tempering copper which he is confident will revolutionise the use of metals. Mr. Shevlin has already applied for a patent for his formula, which has been pronounced a valuable discovery by experienced mechanics, who have learned something of its results. The inventor has shown a reporter several tools made of copper which have been successfully tempered by the process. One was a knife, the blade of which was hard and sharp as steel, and as pliable. Another was a chisel, which had been tested by hard usage. Mr. Shevlin says he has worked on this formula for five years. He says the process is very simple, and can be utilised very economically. He states he is satisfied it will undergo successfully the most rigid scientific test. He says he can temper copper until it can be employed for the same purposes as steel and the harder metals, in cutlery, tools, and machinery, and states that it has an advantage over other metals, as it will not corrode, rust, or soften when subjected to the most intense heat.—*Pittsburg Dispatch.*

JOBBING WORK.

USEFUL hints are often found in places where they are not expected, and the following by Mr. S. A. Betterman, in the *American Machinist*, may be deemed interesting:—One of the various jobs which I noticed passing through the Judge's hands was making occasionally one or two tube-expanders of the Dudgeon type. The interesting feature was the making of the three oblong holes A A A in the body, Fig. 1, of the expander. This piece was held as at F, Fig. 2, in the tool block of the "rise and fall" rest of the lathe, and clamped by the stump of a boring tool B, tightened by the tool-post screw. The flat drill, shown enlarged at E, was held in the chuck, and by feeding the carriage towards the head-stock, the two outer circles of the oblong hole were drilled, and then by using the cross-feed the sides of the hole were milled straight. The piece was reset for the second and third holes, which were drilled and milled in the same manner.

This flat drill, ground with reasonable care by hand, can be made to cut nice short keyways, holding the drill in the lathe chuck and clamping the shaft to the tool block. It can be made to bore or mill holes or grooves considerably larger than itself, adjusting the size by setting it out of the centre with the independent chuck jaws and cutting with but one lip. As a makeshift it is sometimes very useful.

The heads of covers, Fig. 3, for the cylinder or casing of a rotary engine having the groove H to be finished came to the Judge. Hand work was useless, so a former A, Fig. 4, was made, the shape and size of the inside of the groove H, Fig. 3, and screwed to the side of the lever B, the screws passing through the lever and tapped into the cylinder head and holding the three pieces firmly together. A piece of ⅝in. round iron was bent at a right angle and the shank threaded and held fast in the lathe tool block, as at C, by the two nuts. This formed a fulcrum for the lever B. A worn-out lathe centre still had stock enough to make a stud D, the width of the groove H in diameter. The flat drill or mill E, ground carefully, was chucked true, and a helper at the end of the lever B held the former firmly against the stud, while the carriage and tail-stock spindle were fed toward the head-stock till a hole was drilled the depth of the groove intended. Then, by feeding slowly forward and backward with the cross-feed screw, the former at all times held firmly against the stud while following around it, a very fair job of profiling was accomplished. Five days' hand work wouldn't have made as good a job of those two heads as five hours, making the rig and machining the grooves, did by this method.

INTERNAL COMBUSTION MOTORS.

THE high economy which has been demonstrated to be possible in the case of the Diesel motor has attracted much attention to internal combustion motors of all sorts during the past year, and there appears to be little doubt that much better results can be attained from various forms of such machines than had hitherto been thought practicable.

Among those who have devoted attention to this subject is the chief engineer of the well-known firm of Ganz and Co., of Budapest, Prof. Donat Banki, and a very complete discussion by him of the principles involved in the economic performance of internal combustion motors is given in a recent issue of *Le Génie Civil*, being a translation of the original paper in the Hungarian review *A Magyar Mérnök*.

Assuming that the phenomena in the cylinder of a motor of the internal combustion type may be considered simply as those belonging to the variations in pressure and volume of a given mass of air under varying conditions of temperature, Prof. Banki proceeds to investigate the influence of various modes of introduction of heat in the cycle. This he does, as others have also done, by the study of various curves, constructing what are practically indicator diagrams for the different conditions assumed. By comparison of these curves he then seeks to determine which one, for a given compression, may be expected to give the highest degree of efficiency.

By a similar analysis Herr Diesel concluded that the greatest economy would be secured by isothermic combustion, the loss of heat by conversion into work exactly corresponding to the generation of heat by combustion, the temperature during expansion therefore remaining constant, and these conditions he sought to realise in his motor. This method involves a continuous combustion, and not a very rapid or almost instantaneous explosion, and Diesel has designed his motor so as to feed the combustible gradually into the cylinder, where it is slowly and completely burned.

Prof. Banki, however, deduces that the highest economy is attained when the terminal temperature is the lowest, assuming in each case the same quantity of heat, and demonstrates mathematically that this is secured by a motor of the explosion type, the combustion being practically instantaneous.

This conclusion is based upon the same degree of compression in each case, and a further examination is then made into the influence of compression upon economy. Here some interesting deductions appear. The compression may be either isothermic or adiabatic, and Prof. Banki shows that the latter should theoretically give the best result. The degree of compression, however, has an important influence. For moderate pressures it appears that the indicated and mechanical efficiency is greater for explosion motors than for combustion motors, while for high degrees of compression the two varieties approach more nearly in efficiency, and for very high compressions the advantage is on the side of the combustion motor.

In the case of high compressions it is necessary to compress the air separately from the fuel, in order to avoid premature ignition, and this is the practical method adopted in the Diesel motor.

The conclusions of Prof. Banki might readily be checked by experiment, and, in fact, such tests as have been made with motors of the types discussed confirm his deductions. For motors operating with slow combustion the compression should be as nearly adiabatic as possible, and there should, therefore, be as little cooling of the cylinder as possible, only sufficient to prevent injury to the cylinder and piston being employed.

If the combustion can be controlled, the best result should be expected by providing an isobaric combustion, the pressure neither rising nor falling until the fuel is consumed, and this with adiabatic compression will give a high degree of economy if the compression is sufficiently high. If the compression reaches 30 atmospheres the thermal efficiency may reach 40 per cent., a degree not yet attained in actual practice.

Prof. Banki is most ready to give Herr Diesel full credit for the work he has done in indicating and applying the correct theoretical principles to internal combustion motors, and considers his work to be as important in petroleum motors as was the introduction of the four-cycle compression gas-engine by Otto in its line.

Prof. Banki has himself devised a motor in which high compression may be employed in connection with the simultaneous admission of the combustible without danger of premature ignition, by using a sprayed injection of water into the working cylinder. The presence of the moisture delays the ignition to any desired point, while after, or rather during, the combustion the spray is converted into steam, the motor practically becoming a steam-engine using superheated steam generated in the cylinder itself. Several engines of this design have been constructed, and show an efficiency equal to that of the Diesel motor, a consumption of only 208 grammes of petroleum per horse-power-hour being required, with a mean effective pressure of 10 atmospheres.

In these circumstances it appears as if it were only a question of a very brief time before petroleum motors designed upon the principles demonstrated by Diesel, Banki, and others will come into general use, not only for small powers, but also for general service.—*The Engineering Magazine.*

THE NATIONAL CYCLE SHOW.

THE National Cycle Show was opened at the Crystal Palace on Friday, and the whole of the nave is devoted to up-to-date exhibits of the principal firms in the trade. The chief novelty is the introduction of the free wheel and various rim-brakes, while a considerable space is devoted to motor-cycles and cars of every description. A new feature which is likely to prove a special attraction will be the electrically-driven machines for manufacturing the component parts of a cycle. Our readers who are acquainted with the well-known "Juno" cycles will find a varied assortment on show at the stand of the Metropolitan Machinists' Co., with all the latest improvements at a reasonable price for cash or credit; and the Dunlop Tire Co., whose exhibit is appropriately the largest in the show, have an interesting display of their various rubber goods. Messrs. R. Melhuish and Sons, of Fetter-lane, who are known to our readers as the best makers of tools of every description, have an interesting exhibit of lathes, drilling and planing machines, wheel-cutting and dividing apparatus, brazing forge and lamps, cycle stocks and dies, vices, dies, shop tools, and general engineering supplies.

WHAT is said to be the largest rope cable in the world has been in use for some time for the Glasgow District Subway. It was manufactured by D. H. and G. Haggie, of Sunderland, and its weight is about 55 tons. Its life has proved to be 14½ months, the previous record being 10½ months, and during this time it has run 85,000 miles, whilst the previous best record was 61,000 miles.

SCIENTIFIC SOCIETIES.

ROYAL METEOROLOGICAL SOCIETY.

THE opening meeting of this Society for the present session was held on Wednesday evening, the 15th inst., at the Institution of Civil Engineers; Mr. F. C. Bayard, LL.M., President, in the chair. Mr. R. Curtis read a paper on "The Diurnal Variation of the Barometer in the British Isles." The principal features of a curve exhibiting the diurnal march of barometrical pressure are two minima and two maxima—the first minimum occurring early in the morning, and the second in the afternoon, while the first maximum falls in the forenoon, and the second not far from ten o'clock in the evening. In the Tropics, the oscillation may amount to as much as a tenth of an inch; but its amplitude decreases as the latitude increases, and the greatest amplitude in the British Isles amounts to not much more than three-hundredths of an inch. The author discusses the mean hourly readings of the barometer from 25 years' observations (1871-'95) at four observatories maintained by the Meteorological Council—viz., Kew, Aberdeen, Falmouth, and Valencia. The author is of opinion that the primary cause of the diurnal oscillation of the barometer is solar radiation, and that its amplitude is chiefly determined by the temperature of the lower strata of the atmosphere. The relative magnitudes of the different phases of the barometer oscillation, as observed, depend largely upon the geographical position and physical surroundings of the place of observation, in so far as these are capable of modifying its temperature conditions, and especially the relative distribution of temperature over the regions immediately surrounding it.

Mr. G. J. Symons, F.R.S., described some experimental observations which he made during the hot weather in July with two thermometers 1ft. below the surface of the ground, with the view of ascertaining (1) the influence of slight shade, (2) the amount of daily range, and (3) the approximate curve of daily fluctuation.

QUEKETT MICROSCOPICAL CLUB.

THE 372nd Ordinary Meeting of this club was held on Friday, Nov. 17th, at 20, Hanover-square. Dr. J. Tatham, M.A., President, in the chair. A series of photographic reproductions of the plates in Ehrenberg's "Radiolaria from Barbados," published many years ago as a supplement to the "Mikrogeologie," and now scarce, was presented by Mr. Mottram. Messrs. Baker exhibited Leitz's new travelling or portable microscope, with folding base and removable stage, coarse adjustment by rack, fine adjustment on the Roberval plan, Abbe condenser and Iris.

Mr. A. Earland read an elaborate paper on the "Radiolaria or Polycystina," dealing with their classification, morphology, physiology, and distribution. The next meeting will be held on Friday, December 15th.

IN designing a system of town sewerage, a flow of 3½ft. per second should be the minimum velocity permissible in a small sewer, and 3ft. per second in a large sewer.

Life and Immortality.—"We know that of late years," says Sir E. Fry, continuing his account of the Mycetozoa in the November issue of *Knowledge*, "many interesting theories and questions have been propounded in relation to the great fact of death, and that the entrance of death into the great chain of organic life has been watched and studied. One view, to which Prof. Weismann has given great prominence, is that unicellular organisms possess an unending duration, or, in other words, that though susceptible of death by external force —as, e.g., by fire—there is no natural death, but on the contrary a potential immortality. . . . Another view put forward (not by Weismann but by Götte) holds that death is always connected with reproduction, and is a consequence of the latter in the lower animals. Lastly may be noticed another view, also propounded by Götte, that the first form of death is to be found in the phenomenon known as encystment, which occurs when an organism which has been alive and exhibiting the phenomena of motion becomes stationary, develops a cyst or coat around it, and after a period of rest and suspended animation again revives when the favouring circumstances occur. . . . In the higher organisms we know of death in two forms, the death of a part cast off, as when we shed a hair or lose a tooth, or as when a tree casts off its dead leaves; and, secondly, the death which affects the whole organism; and further that reproduction is in a great majority of the higher organisms accompanied by the casting off of some parts of the organism which have been devoted to the nutrition and protection of the young offspring. In plants we know how the floral envelopes drop off, and how the seed vessels are allowed to fall and decay when their duty is done; and corresponding phenomena exist in the animal world."

SCIENTIFIC NEWS.

THE elaborate preparations made in some places for observing the meteors seem to have met with little recompense, for although some observations have been made in America, fogs generally prevented the "seeing" in this country and on the Continent, even if there was anything to observe. The authorities of Vienna Observatory sent a party to Delhi, and others to elevated positions such as the Kahlenberg, near Vienna, and the Schneeberg and the Sonnwendstein, from which positions considerable numbers of meteors were noticed, but nothing to be compared to what was expected. A violent snowstorm burst over the Alpine region, and seems to have prevented the view of any meteors that were to be seen. From Treptow Observatory there is a report that falling stars were seen in "large numbers," and from Madrid Observatory a note that a "number of the Leonids" were seen.

Mlle. Klumpke, of the Paris Observatory, who was sent up in a balloon by the Meudon Observatory and the Aërial Navigation Society to observe the Leonids in the region above fog or cloud, alighted at Saint Germain-sur-Ay, near the Channel. She saw only twelve shooting stars, seven of them of the 1st magnitude. She saw more on a following night. M. de Fonvielle thinks that the greatest display was on Tuesday night, when 80 were counted by another balloon observer.

It is announced that at Yale Observatory a dozen photographs were secured; but, taken altogether, the reports received indicate a "failure."

It appears that three more small planets have been discovered by Dr. Max Wolf and Herr Schwassmann, of Königstuhl, Heidelberg, in addition to those mentioned last week. Two of these were noted on Oct. 31, and the other on Nov. 4. They require verification, especially as one of them had been photographed some weeks earlier than the date given.

The death is announced of Sir John William Dawson, M.A., F.R.S., &c., Emeritus Principal of M'Gill University, at the age of 79. Born at Pictou, Nova Scotia, in October, 1820, he studied in Edinburgh, returning to his native land with a youthful love of natural history, strengthened by a sound scientific training. He soon became an authority on the geology of his native province. He devoted himself at first to general educational work, and by 1850 had come so well to the front as to be appointed Superintendent of Education in Nova Scotia. Five years later he was called to a yet more responsible position. In 1813, a citizen of Montreal—James M'Gill by name—had left his property for the foundation of a college in that city. But it was not till 1821 that the institution received a charter granting it University powers. Dawson was appointed Principal in 1855, and during his long rule did much to raise M'Gill to its present prosperous condition. He was not only a teacher and administrator, he was also a diligent worker at more than one branch of geology, the author of several books and of many contributions to scientific journals. He was knighted on the occasion of the visit of the British Association to Montreal, having received a C.M.G. two years before. He was a Fellow of the Royal Society of England, and first President of that of Canada, President of the American Association in 1882, and of the British Association in 1886.

Prof. Johann Carl Wilhelm Ferdinand Tiemann died last week at Meran. He was born at Rübeland in 1848, became a Ph.D. of Göttingen in 1870, and in 1882 was appointed professor of chemistry in Berlin University, undertaking from the same date the editorship of the *Proceedings* of the German Chemical Society. Prof. Tiemann was the author of numerous important researches of the most abstract nature in pure chemistry, having for their object the discovery of the constitution of the camphors, the terpenes, and other organic bodies. That branch of chemistry, owing to the expense, is much neglected in this country; but now and then a "discovery" is made which produces enormous profits. Prof. Tiemann, for example, discovered methods of making artificial flavouring matters and artificial scents—notably ionone—and he was recently in this country defending successfully an attempt to obtain a revocation of his patents.

Dr. Henry Hicks, F.R.S., who had been hon. sec. and president of the Geological Society, is reported to have died at his residence in Hendon at the age of sixty-two years. Dr. Hicks was an M.D. of St. Andrew's, and a specialist in mental diseases; but he was most widely known as an expert in geology, a subject he made a special study, as he showed by numerous papers presented to the Geological Society and to the British Association.

Dr. Sophie Torma, one of the few women who have distinguished themselves as antiquarians and anthropologists, died last week in Transylvania at the age of fifty-nine. With her sister she made excavations at Tordos, in Transylvania, and was a correspondent of Dr. Schliemann, Prof. Sayce, and other well-known antiquarians.

The death is announced of Mr. Alexander McDougall, who was known about 60 years back as the inventor of what was termed an atmospheric railway, and has been associated since then with a long succession of mechanical and chemical appliances. He was born 90 years ago, at Coldstream, and for many years was in high repute as a schoolmaster at Chorlton Hall, and also at the newly-founded Mechanics' Institute and other establishments, Manchester, where some of the more prominent local men of the present and previous generation gained, as they acknowledged, much benefit from his teaching. He studied under the famous chemist, Dr. Dalton, and among his local friends he then numbered Playfair, Joule, and Angus Smith. He eventually entered into the business of a manufacturing chemist, and produced some important results in the making of disinfectants, baking powders, and aërated bread.

The death of Dr. Camara Pestama at Lisbon on the 15th inst. adds another name to the list of martyrs to science. He caught the plague while studying the disease at Oporto. Dr. Pestama was chief of the Bacteriological Institute at Lisbon, a man in the prime of life, an ardent and most accomplished bacteriologist. It was his verdict on specimens sent to him from Oporto for examination that conclusively established the existence of the plague there in August last. He paid several visits to Oporto to study the outbreak, and was present when the foreign representatives of science visited the city. His contributions to bacteriology are of great value, but being, unfortunately, written in Portuguese, they have attracted little attention.

Sir Richard Moon, Bart., the famous manager and chairman of the London and North-Western Railway, died last week in his 86th year. He has lived in retirement since he left the chair in 1891; but practically he spent the whole of his life on the railway—the "biggest" in all senses of the word—which first commenced the modern system of travelling.

We have already announced that the Copley Medal of the Royal Society is awarded to Lord Rayleigh (p. 312), and it can be stated now that the council of the Royal Society have awarded the Royal Medals this year to Prof. George Francis Fitzgerald, F.R.S., and to Prof. William Carmichael Macintosh, F.R.S. To the former for his contributions towards the advancement of physical science; and to the latter for his work in connection with marine zoology and the establishment of a marine laboratory at St. Andrew's. The Davy Medal is awarded to Mr. Edward Schunck, F.R.S., for his researches into the properties of madder, indigo, and chlorophyll.

The Goldsmiths' Company has, it is stated, made another contribution of £1,000 to the expenses of the investigations which Prof. Dewar is carrying on at the Royal Institution in connection with the liquefaction of hydrogen. Recent discoveries in connection with liquid air point to the possibility of reaching the absolute zero of temperature, and it is not impossible that we may hear soon of the solidification of hydrogen. (See p. 395, June 16 last.)

The first scientific meeting of the Zoological Society for the present session was held last week, Dr. Albert Günther, F.R.S., in the chair. The secretary, Mr. P. L. Sclater, F.R.S., gave an account of his visits to geological gardens on the Continent, and of his explorations in S. Africa, whence he has brought some antelopes and birds that will help to fill gaps in the society's collection. Mr. Smith Woodward exhibited for Dr. Moreno, Director of the La Plata Museum, the skull, jaw, and nasal bones, with some droppings,

of the Ground Sloth, which is said to be extinct so far as Patagonia is concerned. M. Ameghino expressed an opinion that the specimen from which the bones come is the Neomylodon listai, described by him last year. The subject will attract much attention.

The duplicates of the collection of marine zoological specimens brought home by the *Challenger* expedition are now being distributed among the scientific institutions of the United Kingdom —at last.

At a recent meeting of the Royal Horticultural Society, attention was drawn to the injurious effects of fogs. Grapes of the Muscat class have been severely injured at the gardens in Chiswick, and Prof. Church said that at one time the fog was so "pungent" that a hundred buds of a camellia fell in one day. The real cause of the injury is attributed to the presence of sulphurous acid in the atmosphere and to the accumulation of sooty matter.

Some well-known plants have been recognised in the Egyptian Museum at the Louvre, Paris, by MM. Loret and Poisson. They found the remains of the White Lily (L. candidum), the cedar of Lebanon, the citron, and some other plants. There is nothing specially remarkable in these discoveries, as there is no reason to suppose that plants of the kind were not known to the ancient Egyptians, who very likely had a good collection of plants more or less indigenous.

According to a report issued by Reuter's Agency, Dr. Carl Peters will arrive in this country about the middle of December. His expedition was mainly based on an old atlas published in Amsterdam in 1705 with French text, the author being unknown. In this atlas it was stated that "near this place (south of the Zambesi and near the river Manzoro, now Mazoe) is the great mountain of Fura, very rich in gold, which some people regard as a corruption of the word Ophir." This view was also held by the Portuguese writer Couto, who was quoted by Theodore Bent in his "Ruined Cities of Mashonaland." With regard to Fura, Couto said: "The richest mines of all are those of Massapa, from which the Queen of Sheba took the greater part of the gold which she went to offer to the Temple of Soloman, and it is Ophir, for the Kaffirs call it Fur and the Mons Afur." Dr. Peters states that no traveller had visited this region within the last 200 years. He has now rediscovered ancient ruins of Semitic origin, including fortifications, and what he regarded as a temple or storehouse. The whole region is practically uninhabited. He also claims to have found distinct traces of ancient gold-working there.

It is stated that the Board of Trade is communicating with some of the Government departments as to the official recognition of the metric system in contracts. The Standards Department have in preparation a set of "educational models" of weights and measures, &c., for use in schools, which presumably will be introduced soon into the elementary schools.

At Cambridge University an Isaac Newton student in astronomy and physical optics will be elected next term. The candidates must be B.A. and under the age of twenty-five. The studentship is of the value of £200 for three years, and applications should be sent to the Vice-Chancellor between Jan. 16 and 26, 1900.

According to the will of the late Mr. Cornelius Vanderbilt, Yale University will have a legacy of 100,000dol., and Vanderbilt University just half that sum.

THE overhead electric tramway system is about to be adopted in St. Petersburg.

MR A. H. AVERY, of Tunbridge Wells, has just issued a new catalogue for 1900, the special feature of which is the prices for the Avery-Lahmeyer dynamos and motors, which are in favour with those who require appliances of the kind. The machine can be had finished, or parts can be obtained by those who would like to "build" for themselves.

THE wheel-pit of the Niagara Falls Power Company is recessed at a level of about 120ft. below head water, with four large arched chambers cut in the rock. One of these is occupied by the oil and air pumping auxiliaries of the turbines and generators above, and the others are to be occupied by 6,000,000-gallon water pumping-engines, for the service of the Niagara Falls Water Company, which is allied to the Niagara Falls Power Company. This will do away with the steam plant formerly used for pumping the water, and occasion a considerable reduction of the cost.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]

All communications should be addressed to the EDITOR *of the* ENGLISH MECHANIC, *332, Strand, W.C.*

**** In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks; a vice from whence great inconveniences derive their original." —*Montaigne's Essays.*

IS THE UNIVERSE FINITE?

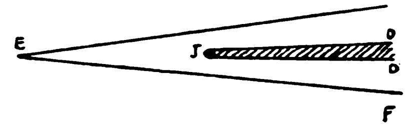
[43041.]—I THINK Mr. Dormer's reasoning on this subject is invalid. In the first place, even the light of the sun is made up of light coming to us from spaces too small to be separately visible. I do not suppose, for example, that the millionth part of a square inch of the sun's surface would be separately visible. It is the putting together of a great number of these small parts that produces a visible effect, and a million of stars, none of which were separately visible, ought, if pretty nearly in the same direction, to produce a visible effect. This is pretty much what occurs with the "Milky Way," with distant clusters, and probably with the Zodiacal Light. Secondly, the telescope makes visible a great many stars that cannot be seen with the naked eye, and the same thing is done by photography, while a further extension of both methods may be expected. Surely it cannot be thought that the objects thus discovered have no effect on the general illumination of the sky. If the distribution of the stars is at all uniform, as the stars become more remote, their number will more than compensate for their remoteness, and the stars whose average distance is 100 times that of a first magnitude star will contribute more to the general illumination of the sky than the first magnitude stars do.

"F.R.A.S." points out that there is nothing like uniform distribution among the stars. True; but the very roughest kind of uniformity would give the results which I indicated. It is only necessary, for example, that a sphere with the earth as centre, and a radius represented by two, should, on a general average, contain eight times as many stars as a concentric sphere with the radius one, and that the brightness of the stars in the two spheres (seen from the unit of distance) should be the same. We are dealing with wide averages extending all over the sky. Now as soon as we abandon the idea that the earth or the sun is the centre of the universe, the natural assumption is that this rough average uniformity will be found to exist equally at all distances from the Solar System, there being no reason why the distribution of the stars should depend on the distance from the sun. But though the sun is not the centre of the universe, he may be one member of a great cluster of stars, and there may be a great thinning-out of the stars when we go to such a distance as to get clear of this cluster. Beyond the limits of the cluster there may be a vacuity or a more sparse scattering of stars, or perhaps other clusters at a very great distance. But the ether which conveys light to us may not extend to infinity. It may be of the nature of a very fine nebulosity, beyond the limits of which neither the telescope nor the photographic plate will carry us.

A finite universe as regards space would seem to indicate an origin in time also, for otherwise we should expect to find it in the final state of equilibrium where no further change could take place. But I see no impossibility in a physical system of limited extent whose changes might recur for ever in very long cycles, and which would not, therefore, tend to any final condition.

With regard to Leonid meteors, while the sky here (Dublin) was very unfavourable, it cleared considerably near the critical period, according to Drs. Stoney and Downing, on the morning of the 16th, all the brighter stars in that region of the sky being visible. I only saw two meteors, one of which did not seem to be a Leonid. I do not think there could have been any considerable number after five o'clock on the morning of the 16th. Several persons appear to have seen bright meteors in Ireland on the morning of the 13th. W. H. S. Monck.

[43042.]—I DO not think this matter is possible of solution by the method pursued by Mr. Gavin J. Burns (42995). It is a great marvel to most men that the distant stars are visible to us, seeing the vast extent of gaseous nebulæ which we know to exist, the certainty of meteoric dust largely prevailing in space, and the certainty of the presence of planets or dark bodies accompanying our sun or stars, and the possibility of dark stars in space. With regard to a star it will probably shine through all space, but we cannot suppose it to occupy 1000 millionth of the space its disc covers, therefore we may assume its light-giving angle will diminish in great distance until the optic nerves have no power of recognition. At this point if a million star images fall on the retina they will all be equally invisible. Further, the interference of the dense matter is absolute; therefore it entirely cuts out all the light beyond. This may be shown by a simple scheme diagram. Let E be the earth or point of



vision, E F, E F¹ the field of view, J a planet, say Jupiter; then the angular space represented by J D, J D¹ will be cut out from light-illuminating space;—every dense body throughout space will act in similar manner. And as regards gaseous media, evident in the spectra of nebulæ, these must refract the light of stars beyond or diffuse their rays to invisibility to us. Wm. F. Stanley.

[43043.]—I DO not see how we can logically assume the stars to be infinite in number. Space—or, to put it more in accordance with metaphysical language, infinite extension—exists of necessity, and matter may be infinitely extended, and the stars may be distributed, but not infinite in number. G. Calver.

THE LEONIDS, ETC., 1899.—II.

[43044.]—THE results of further watches kept here for the Leonids and other meteors are *nil*. The skies have almost constantly remained obscured, either by cloud, fog, or mist. Indeed, at no hour of the nights of November 13, 14, 15, or 16 was there a sufficient space of clear sky to render the observation of a meteor likely.

An observer at Dawlish saw a meteor pass over Perseus from the direction of Leo on November 7. Whether this was actually a Leonid or no cannot, of course, be decided.

From the Surrey hills near Croydon seven meteors (perhaps all Leonids) were seen on November 14, 12h. to 16h. I have received several accounts of watches, but all others record negative results. Walter E. Besley.

Clapham Common, Nov. 20.

[43045.]—THE writer kept watch at intervals from 10th till present date; but almost without result. He is satisfied that if any large meteors had appeared in the open patches of sky which were sometimes available, he should have seen them. Two Clino-Leonids only were observed—one on 10th and one on early morning of 19th—both strong, swift, flash-like streaks, latter from near Gamma Leonis, say, at 155° + 20°. On morning of 14th he had Leo well under view from 5.15 till 6.30, and again from 11.0 to 12.15 midnight, without seeing anything particular. On morning of 16th at 8.35 he noticed a strong reddish flash; but on going out of doors nothing further was observable in direction of radiant. Heavy dense clouds overhead nearly all the time; open spaces and moonlight only at intervals.

Belfast, Nov. 19. W. H. Milligan.

[43046.]—ON Wednesday morning, the 15th inst., between the hours of 4.30 and 6, I, with others, witnessed from 40 to 50 Leonids under the most favorable conditions from Hampstead Heath. During the greater part of the night Hampstead, as in other parts, was enveloped in a fog; but about 4.30a.m. it lifted on Hampstead Heath, and from that time until dawn (the moon setting at about 4.50) we were favoured with one of those very clear nights so rare in this country. The stars were exceptionally brilliant, and the air very steady. Most of the meteors witnessed radiated from the constellation Leo. They were characterised by their swiftness, and the vivid and persistent train they left behind them—they were of a bluish tint. There was one near the radiant point particularly interesting, it burst out into a blaze of light of fully a quarter of a degree in diameter, and after going out left a haze somewhat resembling a comet, and was four or five seconds before it had quite faded away.

Some of the meteois were very short and very swift, so much so that they were merely flashes of light leaving no discernible train. Three of those witnessed were Orionids, these were characterised by being slower and leaving no train.

I may add that there was never anything approaching a "shower," in fact never were two seen in the heavens at once, but the 40 or 50 witnessed were seen during the space of about 40 minutes.

Wm. H. Daw.

9, Belgrave-road, St. John's Wood, N.W.

THE EXPECTED METEOR SHOWER.

[43047.]—WATCH was kept here with the following results:—

Tuesday, Nov. 14, 14h. 30m.—17h. 0m. G.M.T.: Sky completely overcast.

Wednesday, Nov. 15, 15h. 0m.—16h. 30m. G.M.T.: Sky brilliantly clear; not a single meteor observed.

Thursday, Nov. 16, 15h. 0m. G.M.T. onwards: Sky beautifully clear; one or two sporadic meteors; no trace of Leonid shower.

I think the period will prove to be 33½ years, and we shall have the pleasure of seeing the shower next year under much better conditions than obtained a few days ago, owing to the absence of moonlight. Charles L. Tweedale.

Ormskirk, Nov. 20. Curate of St. Paul's.

AMATEUR'S OBSERVATORY—THE LEONIDS.

[43048.]—IN reply to the first question in letter 43018, I am unable to state whether an observing house as a fixture becomes the landlord's property. My own observatory is erected on War Department land, and, that being so, I am under an agreement to remove it at any time if the site is required by the War Office. On change of station I should probably remove the house, and re-erect it elsewhere, having had it made so that the woodwork comes to pieces pretty easily. With regard to the chair, I do not take any precautions against neck-ache, and sometimes suffer a little of that complaint if an object is very high. That is one of the disadvantages of the refractor—the difficulty of bringing the eye normal to the axis of the telescope. I observe in one of three positions generally. 1. Standing if an object is not very high in the sky. 2. Using the before-mentioned chair placed on a wooden stool about 6in. high, when an object has intermediate altitude. 3. The chair alone for high altitudes. On the whole I get on very well with the chair at present in use, which is one of the Austrian bent-wood pattern, light and easy to move. While on this subject it is to be observed that a tripod stand has one great advantage in that one can place one's legs directly underneath it when watching an object pretty high in the sky. A pillar would prevent that to a certain extent. On the other hand, a disadvantage of the tripod is that the slope of the legs prevents the telescope being pointed near the zenith. But this is not of much consequence, for it is practically impossible to observe with a refractor at such an altitude without a specially-designed observing chair or couch.

The Leonids appear to have been a failure this year, so far as a brilliant display is concerned. On Nov. 14 I watched from 12h. 7m. to 14h. 57m. During the greater part of that time the sky was unusually clear. Fifteen meteors were seen, of which twelve were Leonids, none above 2nd mag. in brightness. Nov. 15 again a very good sky on the whole, but flooded with moonlight. Watched from 12h. 48m. to 14h. 47m., and again from 16h. 43m. to 18h. 28m., at which latter hour dawn was rapidly coming on. Seventeen meteors observed, of which twelve were probably Leonids. Particulars of the individual meteors will be sent to Prof. Pickering, in accordance with his request. These are more or less negative observations; but seeing that the sky was very clear, they are of a certain amount of use in settling that there was during the period of observation most certainly no "display," in the popular sense of the word.

The hourly rates of the meteors I make roughly as follows:—

	12 to 13h.	13 to 14h.	14 to 15h.	17 to 18h.
Nov. 14 ..	2	5	8	—
Nov. 15 ..	-	4	1	10

Devonport, Nov. 18. **E. E. Markwick, Col.**

THE LIGHT OF STARS NOT DIMINISHED BY ABSORPTION.

[43049.]—IF an intercepting medium exist, there appear to me to be only two hypotheses tenable as to its constitution:—(1) It may be a gas. (2) It may consist of particles of sensible size, or "cosmical dust."

(1) Modern researches show that a substance can only exist as gas when it is above a certain temperature. At absolute zero all things are in the solid state. A body isolated in space will absorb heat from the surrounding stars, and will radiate the heat received into space. Its temperature is determined by the equality of these two quantities. Now, assuming that radiant heat is proportional to radiant light, the total heat emitted from the stars may be put at $\frac{1}{3000000}$th of the heat received from the sun at the distance of the earth. If this heat were to be absorbed by a body having an area of 1sq.ft., it would raise the temperature of one grain of water 1° C. in about three hours. It is incredible that this exceedingly small supply of heat can raise a body more than a fraction of a degree above absolute zero (or −274° C.) It is certain that no substance can exist as a gas at this low temperature. If it is asked how a nebula can exist at a high temperature, the obvious reply is that the temperature must be maintained from some internal source. The source of energy which supplies heat to a nebula is in all probability the same as that which maintains the heat of the sun—viz., the mutual gravitation of its parts. The most likely way in which the energy of gravitation is converted into the energy of heat is by the continual collision of clouds of meteorites.

(2) There remains the hypothesis that the intercepting medium consists of cosmical dust. Now, I believe it can be shown that the amount of cosmical

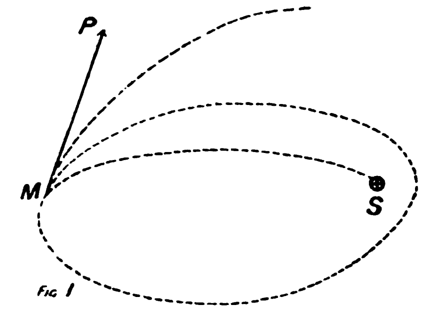


FIG. 1.

dust now existing in interstellar space must be excessively small, if we grant that the stars have existed for an indefinite number of ages past. This can be proved in the following manner:—

Suppose that at some given epoch in past time all space was comparatively full of cosmical dust. Then it is evident that if the dust were at rest it would speedily (as time must be reckoned in the evolution of a sidereal system) be gathered by the power of gravitation into any larger masses that might then exist, whether such masses were lucid stars or not. It follows that the cosmical dust that now exists must have been in motion, and we have to show that the ultimate result would be the same as if the particles were at rest.

Let S be a star (or other large mass of matter), and let M be a particle having an initial velocity in the direction M P. Then one of three things will happen—the particles will fall into S, or it will move in an elliptic orbit round S, or it will move in hyperbolic orbit, having S as a focus. (For the present purpose a circle is regarded as a species of ellipse, and a parabola as a species of hyperbola.) It depends on the initial velocity which of these three things will happen. We shall first show that the particle will move in an elliptic orbit round S only in very exceptional circumstances. In the first place, the initial velocity, v, of the particle must not exceed a certain critical velocity, V (which is independent of the direction M P), in order to describe an elliptic orbit. In the second place, for a given point and a given direction, there is a certain velocity, U, which must be exceeded, otherwise the particle will fall into S. It is evident that the particle can only describe an elliptic orbit round S when V exceeds U. The following table gives the actual values of V for the sun:—

Distance N.S. Earth's distance = 1.	V in miles per second.
1	26
10	8·22
100	2·6
1,000	0 822
10,000	0 26
100,000	0 082

It will be seen that an elliptic orbit of large dimensions is only possible when the aphelion velocity is small compared with planetary or stellar

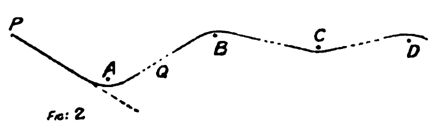

FIG. 2.

velocities. Again, only those orbits whose perihelion distance is greater than the sun's semi-diameter are admissible. Then, again, an elliptic orbit is only possible when the attraction of the central body predominates over all neighbouring bodies throughout the orbit. Taking all these things into consideration, it appears that an elliptic orbit must be the exception, and not the general rule, in the case of cosmical dust.

We have next to consider the case of hyperbolic orbits. This is illustrated in the above diagram. P is a particle of cosmical dust moving in the direction P R with a velocity v. A is a star lying near (but not in) the direct path of the particle. Then there is a certain velocity U_a, which v must exceed in order to escape A. U_a will become greater with the mass and volume of A, and will become less as the distance of A from P R becomes greater. If v exceed U_a, P will move round A in a hyperbolic orbit. At Q, where A Q = A P, its velocity will be v, as at first. It will then move in a practically straight line, at a nearly constant velocity, till it approaches some other star, B. It will again escape, provided v exceeds a certain velocity, U_b. It will thus describe a series of hyperbolas round A, B, C, D, &c., until it at last falls into Z. That this will ultimately happen is obvious, if time be unlimited and the number of stars indefinitely great. It is also evident that the greater the initial value of v, the longer the particle will escape.

Returning, now, to elliptic orbits, it appears that particles moving in them would by degrees also be eliminated, but in a somewhat different manner. Suppose a particle to be moving round A in an ellipse whose major semi-axis is comparable to the distance that separates one star from another. Then, owing to the proper motion of neighbouring stars, some other star, B, might approach near enough to the orbit of the particle to overcome the attraction of A and divert it towards B. As the velocity of the particle must be small (relatively to A), the probability of its falling into B will be comparatively large. It is obvious that the larger the orbit the greater is the probability of the particle being picked up by a neighbouring star.

Taking everything into consideration, it appears that the quantity of cosmical dust in interstellar space cannot perceptibly diminish the light of such stars as are visible to us.

Gavin J. Burns, B.Sc.

TELESCOPE HOUSE.

[43050.]—COL. MARKWICK'S description of his telescope house (42996) interests me very much, because having had a long experience of sliding roofs, and knowing how small improvements are sure to keep suggesting themselves from time to time, I can foresee that his present structure is destined sooner or later to develop into something more worthy to be called an observatory. But, in the mean time, there is really no necessity for the Colonel to march backwards and forwards along that plank shoving the roof before him, when it may be so easily avoided. If he will adopt the following simple plan, he will find that he may not only give up his walk along the plank, but that he—or even the little assistant whose face peers out between the legs of the telescope—may stand perfectly still and draw the roof off and on with the utmost ease. He has only to screw two pulleys about 2in. diameter on to the woodwork of the building close under the roof, as near together as possible, and exactly in the centre at the end where the roof draws off. Over each pulley pass a light rope, fasten one to a ring screwed into one end of the roof and the other to a ring at the other end. One pulls it off, the other pulls it on, that's all. It is quite simple, and, what is better, it is efficient.

I see that Col. Markwick makes his roof to run upon small brass rollers. I should have preferred large ones if I used them at all. They may answer for a time with a very light roof, but with a roof of any weight I should not at all like to try them. I never did, and have always used small cast-iron flanged wheels 2in. diam., which run upon iron bars ½in. square screwed down to the woodwork. These run beautifully, and there is nothing to wear out or go wrong. However, we need not say any more about these until the Colonel is building his next house.

I notice that Col. Markwick has taken precautions against the possibilities which might happen in a gale of wind by clamping his building to a wall. He does not mention whether he has taken any special precaution about the roof. Very likely he has; but if not, I hope the necessity for it will not be impressed upon him in the way in which it was upon me. In the first observatory I erected, which was a rather more ambitious structure than the Colonel's, the roof of that part which covered the telescope was flat, and covered a space sufficient to work comfortably a 4¼in. equatorial in, and being boarded and covered with zinc was, as I thought, sufficiently heavy to take care of itself, the situation not being an exposed one. My feelings, therefore, received a rude shock one morning on looking out of window during a gale of wind, and seeing the said roof lying in the middle of a flower-bed some 12 or 15 yards off. I thought, once of this sort of thing was enough, so I got four strong pins, which I fixed to the woodwork in the four corners of the observatory, arranged so that they ran home into four corresponding eyes when the roof was closed. After this, I was able to regard all gales of wind with perfect indifference.

It is going, perhaps, rather into the development period, but I may add that in my present observatory, the space being larger than before, the roof is in two parts, each half running off in the opposite direction and meeting in the middle. I find this very convenient, as I can open just as much or as

little of the roof as I want for observation at the moment. This roof is ridged and is tolerably heavy, but it runs quite easily and each half bolts itself as it runs home.

If there is anything I have not made clear in the above, I shall be very glad to give Col. Markwick any further information that he may wish for.

I see in this week's issue of the "E.M." that a correspondent (43018) asks Col. Markwick two questions. To the first question I believe it may be replied that a wooden erection, such as the one alluded to, if raised from the ground—as, of course it should be if it has a floor—merely on loose bricks, can certainly be removed by the tenant, not being fixed to the soil or to any other building. The second question I leave to Col. Markwick to answer. One could hardly expect to find a Dawes observing chair in an edifice of such humble pretensions!

Crewborough, Sussex. J. H. Jenkinson.

SODOM DESTROYED BY THE LEONIDS.

[43051.]—This was a view I took up in 1866 when the connection of the Leonids with Tempel's comet of that year was established by Schiaparelli, and the more I have considered it the plainer does it seem to me that, not only did meteors destroy the cities, but these particular ones. The date of the event is correctly given, in Ussher's notes to Genesis, as 1896 B C., and it was a more important event than readers commonly infer. It cleared Palestine of all its inhabitants, the Amorites, who fled in all directions, as we should avoid, in a room, the place where a bit of ceiling had fallen. Though four cities perished, we are told it was only on two, Sodom and Gomorrah, that the fall took place. Lot and his daughters fled to Zoar, but dared not stop in its ruins. Fearing another fall of sky, they took refuge in a bomb-proof cavern, and believed themselves the only human beings left in the world. While Lot's wife lingered looking back, a fragment of one of the meteors of salt fell on her and instantly buried her. The heap of salt was shown to her grandsons, and thus arose the saying that "she became a pillar (or monument) of salt."

The comet of the Leonids, we must remember, has only twice been seen: in April, 1366, and in January, 1866. The interval was 499 years nine months. This, divided by 15, gives for an average period 33·316 years. Before this was known, a period of 33·18 was reckoned from the single appearance alone. This was a wonderfully good approximation. But when Leverrier computed from this a date 126 A.D. for the comet's approach to Uranus, the error became prodigious. It was 52 periods (or rather 52½) ago. The difference between 33·18 and 33·316 is ·136 of a year. Fifty-two times ·136 make full seven years, during which Uranus moves about a twelfth of his orbit. So Leverrier's origin for the Leonids in A D. 126 is utterly disposed of.

Now multiply 33·316 by 113, and we get 3,761 years, the exact number to carry us back from 1866 to 1896 B C. The interval is one year less, remember than 1866 + 1896, because from 1 B.C to 1 A.D. is not two years, but only one. The catastrophe at Sodom was the right year out of 33. Again, it was at the right hour, sunrise, and the latitude of 31° answers to the declination of the radiant, so that the fall would be vertical, not sloping, but so that it might be said "the Lord *rained* upon" the cities.

The geology of the "Sea of Lot" has to be considered too, because there is no other valley on earth, I believe, to which the strata descend on both sides, as if it were punched in by a blow. We read in Genesis xiii. 10, "That all the plain of Jordan was well watered everywhere before the Lord destroyed Sodom and Gomorrah, like the garden of the Lord, like the land of Egypt as thou goest unto Zoar." The present barrenness is entirely due to the salt and not to the bitumen, which already existed, xiv. 10, for the vale of Siddim was full of bitumen pits, which nowise interfered with fertility. The water of the sea is now deepest near the north end; but the chief hill of salt is at the south end, a rivulet of salt water issuing from a cavern at that end. The alluvial deposit is declared to be deeper under the Jordan north of Jericho than under any part of the sea. I would suggest that the lake was, before the catastrophe, north of Jericho, and received rivers from the south. It was lower than general sea-level, but not so low as at present. The meteors fell on these southern streams and depressed them, bringing the lake 40 or 50 miles southward.

If it be thought unlikely that huge meteors fell only at that point, we must remember that Herodotus describes remarkable hills of salt in different parts of Africa. One of these is near Biskara, in Algeria, that is described as appearing exactly as if fallen from the sky. Why may not all of these have fallen the same day as the destruction of Sodom? Similar falls may be expected whenever the comet's appearance is deferred till October, or, still worse, till the first half of November. When we arrive at the node very shortly after the comet, these exceptionally heavy showers may be expected.

E. L. Garbett.

PHOTOGRAPHING A "SPIRIT," AND THE SOCIETY FOR PSYCHICAL RESEARCH.

[43052.]—As on former occasions, "F.R.A.S." has rather disparaged the Society for Psychical Research. I think it fair to mention that it is they who, in their *Journal* for November, have taken the trouble to correct his statements.

So far from the society being devoted to superstitions, it is really devoted to their study, the necessity for specialisation in which is shown by the present instance. "F.R.A.S.," having into the very natural error of publishing such matter without laborious verification, now announces that in future he shall reject all similar stories without examination.

I write to point out that these are precisely the errors that have hitherto prevented any exact knowledge in these outlying departments of psychology. The whole region of folk-lore, whether superstitious or supernormal, will never be either exploded or explained without plenty of hard work. And whatever the outcome of the society's work may be, its subject-matter, the human mind, is, as Stanley Jevons said, of more importance to mankind than all "F.R.A.S.'s" stars and nebulæ.

I have heard a leading physicist object to biological work as "messy," and "F.R.A.S." objects to this sort of psychology as "full of rogues and dupes," just as an ordinary pedestrian would object to rope-walking. Psychical research is the slack-wire of the sciences, and if "F.R.A.S." would become perfect in all the scientific virtues from agnosticism to suspense of judgment, he cannot do better than engage in psychical research. He will need them there as nowhere else.

A Fellow of the Geological Society.

[43053.]—I hope "M.I.C.E.," in letter 43036, p. 320, does not wish us to believe that the particles or weights in his diagram are in stable equilibrium. The centre of gravity must surely lie to the right of the vertical line which passes through the axle or centre. Again treat the particles as being supported on incline planes, find the resultants acting at right angles to the planes, multiply each resultant by its distance from the centre or axle; add the moments of those to the right of the vertical line together, and also those to the left, and compare the moments.

If that does not satisfy, take a straight steel wire, bend it with equal arms to contain an angle of 45°, hang it with the angle across a fulcrum, place a 1lb. weight on each arm but at different distances from the fulcrum, and note the position of equilibrium. Compare this with his diagram, and see if it is not composed of a number of similar appliances.

William E. Tanton.

[43054.]—If Mr. G. will get Dircks's "Perpetuum Mobile" from the nearest reference library, and will diligently study the numerous designs submitted of this wheel-and-weight idea during the last century and a half, he will see the futility of spending his time on this side of the subject. If after reading this book he will look through back numbers of the *Scientific American and Supplement* he will find several other and more modern developments of this idea—all to the same purpose—non-success.

If, then, he is not convinced, let him pull his coat off and construct a model wheel, say 12in. diam. Let him make this go (if he can), and then send you, Sir, an untouched negative of it for your process man to make a block from, and let Mr. G. add full particulars as to size, &c. Then he will have have some grounds for speculating about a wheel 88ft. in diam., and might have some success if he approached the proprietors of the Blackpool Big Wheel with a view of giving it a gigantic trial.

Hightown, Manchester. W. Ainsworth.

[43055.]—With reference to the design of a perpetual-motion device on p. 320, will any reader explain the difference between that and the practically identical device shown on p. 48, of Dircks's "Perpetuum Mobile," which is really about five centuries old (known; how much older, I should like to know). As to hearing "speech 500 miles off," and so on—no one has, unless there was some "energy" about, and that's the "screw" the perpetual-motion machine wants.

P. M.

[43056.] — May I make a suggestion to Mr. Gibert, who writes letter 43035? I do not wish to make it in any carping spirit, but in order to be of some slight assistance when he comes to make his machine for exhibition at the 1900 Paris Exposition.

I would suggest that instead of fixing a brake to prevent his machine racing or running away with machinery it was driving, he should dispense with roller bearings, using plain bearings in place of them; these would not only be much cheaper to make for a machine the size proposed, but would also act to a certain extent as a brake by their increased friction. This, to my mind, would probably be a quite efficient brake without anything more.

The spectacle of a machine (model or otherwise) driving a dynamo lighting glow-lamps without any power beyond what power it gained from *its own mechanical parts* (with or without a brake), would certainly be one of the wonders of the Exposition, if not *the* wonder, and I am sure Lord Kelvin, our greatest scientist, as well as all our lesser scientists, would gladly pay to see it, and would hail the proud discoverer as the greatest scientist of them all.

Martin.

STONEHENGE.—TO "F.R.A.S."

[43057.]—Is there any other possible cause for the change in azimuth of the sun's rising point at the summer solstice than *the change in the obliquity of the Ecliptic?* If not, I certainly cannot see how the data to be obtained at Stonehenge can help to determine *its* date.

I know Stonehenge well, and have witnessed sunrise there at the summer solstice. The sun, as viewed from the "altar stone" so-called, may be said to rise at the point indicated by the "pointer stone," but the means of observing are not accurate enough to decide whether the sun's centre or northern or southern limb is in line with the pointer.

The change in azimuth due to change in obliquity of the Ecliptic must be but slight; and the above means of observation *much too coarse* to detect it or measure it with accuracy.

I hold that Stonehenge dates from far earlier than any Annus Domini.

Peasmarsh. F. B. Allison.

[43058.]—The letter from "F.R.A.S.," in your issue of the 17th inst., refers in very kind terms to my estimate of the date of Stonehenge—viz., 476 A.D. A subsequent and more accurate calculation gives 425 A D. But I wish to state that, as the change of the obliquity of the Ecliptic is very slow, I think that we should allow a margin of a century or two on either side of this latter date. It should also be borne in mind, as "F.R.A.S." points out, that we have to assume that the original orientation was accurately directed to the solstitial summer sunrise, and that we can exactly recover that orientation. Prof. Petrie's date, founded on the astronomical evidence, is 730 A D ± 200 years, with a possible date of 400 A.D. This estimate points to the ruin being post-Roman. The problem of the date of Stonehenge is a very difficult one, and, when all the available evidence is taken into account, it seems not unlikely that the structure is partly pre- and partly post-Roman. C. T. Whitmell,

President Leeds Astronomical Society.

Leeds, November 17.

DENSITY AND SPECIFIC GRAVITY.

[43059.]—Your correspondent in letter 43037 seems to be puzzled as to the meaning of density and specific gravity. The specific gravity of a solid or liquid is its weight volume for volume, as compared with the weight of water, which is taken as unity. A liquid half as heavy again as water will be 1·5 s.g. With any kind of a gas air is taken as the standard of specific gravity, and is also unity. The s.g. of nitrogen being lighter than air is ·97, whilst oxygen being heavier is 1·1 specific gravity. The "density" of a gas is its weight volume for volume compared with hydrogen, and cannot be looked upon as having anything to do with compactness. As to molecules, the "Law of Avogadro" says: "Under similar conditions of temperature and pressure equal volumes of all gases contain the same number of molecules." But from this fact, all gases are not of the same density, as your correspondent must know. "The molecular weight of any gas is the weight of that volume which occupies the same space as do two parts by weight of hydrogen." As the molecule of hydrogen weighs two, the density of any gas, whether elementary or compound, is identical with the half of its molecular weights. As the molecule of hydrogen weights two, and that of hydrochloric acid = 36·37, the density of HCl gas is 18·18.

Handel.

REDUCING INTENSITY OF LIGHT: TO MR. ELLISON.

[43060.]—May I be permitted to thank your correspondent just named for his much-too-flattering references to the "depths of mathematics" to which he supposes me capable of descending in trying to solve the very shallow problems connected with "dark-glasses"? He appears, however, to imagine that I have added complications to the conditions. The "conditions (I) introduced" were precisely his own. Indeed, the very terms of his own counter-criticism on mine upon his former letter refer to the *ordinary use* of dark-glasses—viz., to look at the sun. (Who uses them to look at stars?) His thanks to me as expressed in letter 42948 were in these words: "for his criticisms on *my* various proposed devices for reducing the intensity of the *sun's* light and heat" (italics mine).

Already I have commented on his use of the word

my (see 42997), and I now draw attention to the fact that the dark-glasses I criticised in that letter were for use under the identical "conditions introduced" by himself—viz., the conditions present in solar observations, where, of course, the image is anything but a mere axial point, and these conditions have in no way been complicated by anything added by me, as is inferred in 43029.

For the mere axial point of an image, as with a star, your enthusiastic correspondent allows there can be no disturbance from such dark-glasses; but who would ever dream of this application of dark-glasses, even with very large aperture telescopes?

Therefore, after all, my contention and reasoning concerning the disturbing effects of dark-glasses so placed upon all the transmitted rays other than those coming to focus at the axial point of the solar image was upon precisely the same conditions (solar) introduced by himself, and I am curious to see how I should be blamed with introducing "complicated conditions" of my own (see 43029).

Again, in that letter, Mr. Ellison says, "my plan was for a plane glass behind the eyepiece" (meaning, evidently, in front of it), forgetting, perhaps, that his plan, as just given to us in 42948, was to employ a glass concentrically *curved*, not a *plane* one, the centre of both curvatures being at the axial point of the solar focus.

As stated already on several occasions in "Ours," my own copy of Webb is of the third edition, 1871, and I find I have quoted correctly. The acquisition of newer editions of such works has not been rendered necessary by my astronomical pursuits, as I get all the information I require *scientifically* respecting such "objects" from the various standard catalogues, societies' memoirs, &c., and I fear I must confess I do not find any loss to science in the absence from these works of the many ornate passages, transcendental comparisons, and abstract reflections upon the "objects" there enumerated, which abound in works of the previous class.

H.

HABIT OF AMUSEMENT IN ROTIFERS: A REPLY.

[43061.]—Dr. Weir's note, on p. 311, on the remarkable sportive habits of Melicerta might be supplemented with other more wondrous feats of this wonderful rotiferon. Anyone who has seen this helpless, awkwardly swimming creature when it has had the misfortune to become detached and to be driven out of its tube, will be much interested to hear that it can dart about, in and out of its house, hide behind grains of sand with one eye over the edge or round the corner, and do other frisky gambols. Dr. Weir might well have added that, with a little perseverance and a grain or two of imagination, Melicerta can be seen to use its foot as a prehensile organ, in fact, like an elephant his nasal trunk. When a small rotifer of the genus Rattulus or Mastigocerca comes by, Melicerta will seize it, break off its long pointed toe, and use it as a tooth-pick to clean its teeth, of which it has quite a number, quietly sitting the while on the above-mentioned grain of sand.

The eyesight of Melicerta, with its vertebrate retina of rods and cones, is so powerful that it often tries to look at the observer through the other end of his (the observer's own) microscope, and, no doubt, succeeds. A wonderful creature is Melicerta, and, in order to observe all these and other marvellous habits, a good microscope and a little imagination only are required, such as Dr. Weir seems to possess in so high a degree.

C. F. R.

PROF. BONNEY ON GEOLOGY.

[43062.]—"Silverplume," in p. 417, thinks Prof. Bonney, writing on "Our Planet," had nothing to do with comets. Nevertheless, Comte, the inventor of "Positivism," found nothing so closely bearing on geology as comets, the only class of bodies that can encounter our earth, or that ever have done so.

In his "Positive Polity," Vol. I. of English edition, p. 410, he says, "Scientific knowledge of planetary relations destroys the sense of absolute security from all possible risk of disturbance." . . . . "Collision with a comet, for instance, is a danger from which it can never be proved that we are really free. This final view of our true astronomical position adds energy and dignity to the human character, teaching us that it is from ourselves that we must draw our chief resources against the evils that surround us. It should not fill our minds with useless terror; but it should check the tendency to exaggerated forethought, and to presumption which is inconsistent with the true happiness of man or of society."

P. 411. "Abandoning the ill-defined aim of studying the heavens, it must now propose to itself [astronomy] the study of the earth; regarding the other heavenly bodies simply in their relation to the human planet."

P. 412. "But now that the earth's motion is known to us, it is not necessary to study the fixed stars, except so far as they are required for purposes of terrestrial observation."

P. 413. "And thus we are brought back at last, on theoretical as well as practical grounds, to the old view, adopted from the earliest rise of astronomy, of the preponderating importance of the sun and the moon—the central body round which we move, and that which, in turn, is dependent on us."

P. 414. "Unless this restriction (to sun, moon, and comets) be carefully maintained, we shall be as much encumbered with digression on the planets as we have been with those on the fixed stars."

This was written about 1850, ere any of the 400 asteroids, beyond the four, were discovered, and is more prophetic than anything else in this century I have seen.

E. L. Garbett.

MEAN-TIME DIAL.—TO "F.R.A.S."

[43063.]—The objection made by "F.R.A.S." (letter 42973) is, of course, perfectly correct in itself; but I am sorry he did not give the amount of error due to the proposed mode of marking the dial.

If distances were set off according to a table of the equation of time for a year half-way between two leap-years, and if, through the extremities of such off-sets, hour-lines were drawn, we should get the same result as by the method I gave in my former letter.

As the equation of time differs but little from year to year (it was 14m. 55s. in 1871, and 14m. 51s. in 1898 on this 17th November), it seems as if the error would be inappreciable (allowing for the indefiniteness of the edge of the shadow) until the lapse of a long period of time.

As "F.R.A.S" doubtless knows, the reverse case of making a clock show apparent time was contrived 200 years ago; but, then, one can set a clock right, but not, I suppose, a sundial. I am, however, not sure that an adjustable support *might* not be contrived to secure even this.

As "E. L. G." promised to tell us how to make a mean-time dial, no doubt it is possible to do it.

A. S. L.

STATIC MACHINES FOR X RAYS.

[43064.]—A week or two ago a correspondent stated that static machines required an exposure of three-quarters of an hour for the thickest parts of the human body. That this is not the case with the best machines is shown by the statement of Dr. Pitkin in the *American X-Ray Journal*, that radiographs can be taken through the body at a distance of 1ft. to 2ft. in from one to five minutes.

M.

LATHE MATTERS.

[43065.]—Before purchasing a lathe get a price list from Mr. Milnes, Ingleby Works, Bradford. He advertises in this paper. His 4½in. screw-cutting lathe will turn 16in. in the gap, and 3ft. between the centres. With the back-gear on the pulley revolves nine times to one turn of the spindle, and it is more powerful than most 5in. lathes. You will find it quite large enough for foot-power. You will not do much work sitting down. A seat is very well for ornamental turning.

Willes's tool-holder is the best; you will find a drawing of it by Mr. Evans on page 145, English Mechanic, April 6, 1894.

If you live in London I shall be pleased to let you inspect my lathe, if you will advertise your address.

Metal Turner.

PERAMBULATORS AS "CARRIAGES."

[43066.]—I cannot answer either of "F.R.A.S.'s" queries (letter 43015, p. 313), as I am not aware of any such decisions. My reply (p. 278) is certainly open to his interpretation; but what I intended to convey to "Rota" was that bicycles and prams differ in this respect—viz., that bicycles are *expressly* made "carriages" by the 1888 Act, while prams are not. Their inclusion as such, under the words following in the section: "Bicycles, tricycles, velocipedes, and other similar machines," is a point of legal construction. In my opinion, "other similar machines" means motor-cars, or prams and Bath chairs propelled in a similar manner to velocipedes. I think that had it been thought expedient to class prams and Bath chairs as carriages, they would also have been specified in the above Act; but the Legislature considered the Police Acts against pavement obstruction were sufficient in their case. If these articles are considered "carriages," then must baby and grandpapa duly light up an hour after sunset or be fined 40s., and I have not heard of a case of the kind yet. There is no definition of "carriage" in the Acts of 1835 or 1888 that I know of.

B. H.

THE LIGHTNING FLASH.

[43067.]—I am very pleased that my letter on the above subject elicited that of "C. S. H.'s" on p. 297, because I feel that the inquiry has advanced a step forward. It appears to me, in order to make headway in what is a new line of physiological investigation, the first thing necessary is to clear away all, it may be, preconceived or accepted notions about "epiblastic" or "mesoblastic" origin, and to begin *de novo*—that is, to trace the science or knowledge over again, and to see if it cannot be built up upon simple, plain, and undoubted facts.

May it not be that the principle at work in the system of animal economy of cold-blooded creatures, such as the frog, snake, and lizard, produces its comparate rate of oxidation? Every animal substance, of course, the same as every known substance, must have a chemical nature. Some have gone so far as to assert that crystals live; but I fail to see the evidence of any such thing, but clearer evidence of the affinity of nature acting in accordance with mechanical force. Are there not distinct indications that magnetism causes the contractions and relaxations of our muscles, and that this mysterious power is subordinate to the tension of the will power? After death, if applied soon enough, the circulation of the blood, the digestion of the food, for a limited time, can be carried on by magnetism. It will make the dead kick, strike out the biceps, grate the teeth, roll the eyes, but it cannot make the dead feel or think. These experiments can be carried on even after the brain has been removed. I have never tried them myself, but I have often read this is so. I accept it on the evidence of my fellows who have. I cast about me in a vain search in any or every scientific book, for any other force which is capable of doing anything similar in regard to the animal economy. I cannot but conclude that magnetism must be the mechanical force or *connexus* between the acting will power and the body. I should like very much to hear that someone who has the necessary apparatus would investigate the magnetic and liquid air theory of hot and cold-blooded animals. How comes it that a certain proportion of charcoal in our system is necessary for the support of our life, and that our life ceases when our system gives up its charcoal—the black sweat preceding death? Is it because the charcoal in a healthy human being is as necessary for its dynamo action as are the charcoal or carbon points of an electric light? When the dynamo action of the system stops, the physiology gives out its charcoal in the death-sweat. There is then no further pain, because the magnetism, or æther, or liquid air, has ceased to flow along the nerves, and the system dies. That animal economy is often to be met with capable of generating sufficient magnetism to produce the electric flash will be at once admitted, as in the electrical eel.

In reply to the last question, how do I consider the nerves to be a continuation of the venal system? Look at a decayed bone, you see it is like a piece of lacework throughout. What might be supposed to be solid when fresh proves by decay to be a mass of fine tubes. The next time "C. S. H." has a tooth drawn let him mount the nerve for his microscope. Then let him put the tooth, without extracting the nervous pulp, in a small bottle of nitric acid. Let him watch the tooth dissolve in bubbles. Let him look at the tooth with a magnifying glass while it is dissolving, and he will come to the conclusion that not only the tooth, but the enamel also, is of the same structural formation as the bone. Let him examine a portion of the nerve after it has been acted on by the acid without being entirely destroyed; ditto the remains of the tooth in the nitric acid after it has stood for a day, so that the acid has lost its power of acting further. Use ½, ¼, $\frac{1}{16}$, and $\frac{1}{25}$ obj. glass.

Respecting the frictional resistance of the æther on the ether, and the atmosphere reducing all celestial motion to an ultimate stand-still, I am afraid that is just what is really taking place. Hence, we are mortal. Hence, death. Hence, what is called the "Coal-sack" on the heavenly chart or map. Hence, the order of all things—birth, growth, maturity, decay, and then comes the great question of "to be, or not to be," death, and whether it is a change into something better? It cannot be much worse for some of us, and whether the change is to take place immediately, or the whole universe pass away as the "Coal-sack" increases, and to be succeeded by another universe of immortal love, beauty, and life—for the latter is not worth having without the former?

I see nothing unreasonable in the same law pervading the whole universe; but the clock of the universe and the terrestrial dial, although obeying the same law, must be totally dissimilar in application. To make my meaning more explicit: You know how many divisions of time (months, years, &c.) there are in our centuries. Now suppose a world of such a size that every minute of their 24 hours was made up of a century of our time. What adequate opinion could a human being who lived, at best, a painful life of 74 or 80 years of our little century, form of the events of such a dial of time? Manifestly he could have no conception capable of embracing the events of an hour.

Many leading scientists have held the opinion that there will come a time when time will be no more; the clock of the universe will have run down; the sun will roll a cold black ball, having devoured all the planets. Where will our life be then?

"Infinitude of past time." What is time?

Away in space, away from any revolving world or globe, there can be no past and no future, only the ever "present"—duration. This is simply, time begins when a globe begins to revolve. Otherwise, as there is an equally long eternity in the past to what there is in the future, how did we ever get through the time without end? What has preceded and ended in the present? "Æther and ether." Exactly so. The higher you go the colder it is, and the lower the thermometer sinks. I do not look upon the liquid air, pellucid cold air, as being in its first stage. Depend upon it, that pellucid liquid being in such a hurry to get back to the atmosphere shows that it is itself in a state condensed from a still finer condition, and it strikes me further experiments will elicit the proof of its primitive condition being that of the æther pervading all space; the *æther fire spirit*, the cause of all things.

This world, big as it is, is really but a *mote* in space, so small, that Göthe says: "I greatly wonder it holds a place in thought omnipotent," and when we come to discuss "elements," our intellect comes to a sudden *halt*. I can conceive the idea of an interstellar æther becoming the cold ether surrounding our atmosphere like a cloak, and permeating all the elements of earth of which it forms a part, even to the creation of fire in this succession:—Æther, magnetism, oxygen and æther or ether, electrical fire, oxygen and other elements, ordinary fire, oxygen frozen, liquid air or æther, and the final change back again into æther and electrical fire.

If I could answer "C. S. H.'s" questions, I should be possessed of the definite knowledge that my letter on the lightning flash was written with the hope of eliciting.

A Constant Subscriber.

SAILING BIRDS.

[43068.]—On p. 311 you reproduce a very interesting paper by Mr. L. Hargrave on sailing birds, wherein that gentleman gives a clever explanation of the manner in which some sea-birds sail with motionless wings in the wake of a ship. In the cases he mentions, wave motion is no doubt the prime motive power, communicated through the air to the bird's wings; but it is not applicable to the soaring of land-birds. Some of these can be observed almost any windy day sailing in all directions, against the wind, with it, or in circles. The only motion of their wings seems to be an occasional quick change of angle or a solitary flap, apparently to accommodate itself to the gusts. We know that the wind is anything but a steady forward movement of the air. It varies in force from moment to moment; it blows in "gusts," and swerves in its course continually. Now can it be that it blows in waves or vertical undulations, And the birds take advantage of these in the same way as the sea birds instanced by Mr. Hargrave? I write to ask if there is any evidence of such waves in the air, at the height that soaring birds are usually seen.

The subject of bird-soaring is one that does not seem to be yet explained, and Mr. Hargrave's paper is certainly the best attempt at an explanation I have yet seen. **F. J. G.**

FLYING MACHINE.

[43069.]—In reply to letter 43038, Mr. Maxim and others have shown that it requires at least 1H.P. to fly every 100lb. in weight, so it would require quite 2H.P. to fly the machine as per sketch by Mr. R. D. Hall, taking it to weigh 60lb., as stated, along with the weight of the man. As a man can exert only ⅛H.P. for continuous work, he cannot fly a machine without extraneous power. The difficulty with all flying-machines is to get a sufficiently simple and light motor. As soon as this is done, the design for the machine is a secondary consideration.

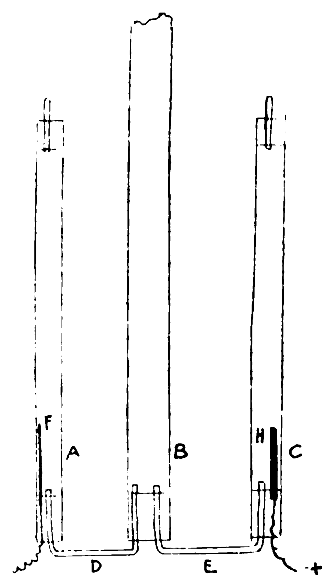
Thornton Heath. **R. F. Moore.**

LONDON SUMMERS.

[43070.]—"F.R.A.S." asks (p. 314) whether the summer of 1899, during a minimum of sunspots, has not been hot and protracted enough. I might point out that this summer is included in my curve (p. 295), being the fifty-ninth of the series; and that, from the point of view adopted, it is not one of the excessively hot ones, in the sense of having 24, or more, very hot days (80° or more). It had 21. Is it not, further, premature to assume that we have reached the turning-point of the sunspot curve? **Alex. B. MacDowall.**

ELECTROLYSIS OF HYDROCHLORIC ACID.

[43071.]—I want to show that when hydrochloric acid is subjected to electrolysis, hydrogen and chlorine are given off in equal volumes. Being unable to get a proper Hofmann's tube, I rigged up the inclosed arrangement. A, B, and C are lengths of ordinary glass tubing. A and C are about ½in. bore, whilst the centre tube B is about an inch. These are connected together by means of quill tubing passing through corks. As nascent chlorine attacks platinum I fitted tube C with a piece of graphite from ordinary carpenter's pencil, wrapped the lower end round with copper wire, which passed through the cork. I then covered the copper



wire with melted paraffin, so that no copper was exposed, but about 3in. of graphite. In the tube A I placed a piece of platinum foil; the upper ends of A and C fitted with glass stopcocks passing through corks. I filled the apparatus with pure concentrated hydrochloric-acid solution, and found joints tight; connected graphite electrode of apparatus with carbon of Bunsen six-cell battery, and platinum with the zinc. Hydrogen given off freely at once from platinum electrode, and this I allowed to escape until the chlorine had thoroughly saturated the liquid in tube C, or until it had become of a deep greenish-yellow colour. But I cannot get much chlorine—never more than half the quantity of the hydrogen. I kept up the operation for five days, changing battery when necessary.

The next week I tried again—this time with as much common salt as could be dissolved in the acid; but, after another five days' operation, could get very little chlorine.

Will Mr. Bottone or other gentleman point out the cause of my failure? I thought perhaps the small size of my quill tube connections might have something to do with it (about one-eighth bore), the small section of liquid offering a high resistance. But as I obtained hydrogen freely (the tube filled in an hour), the chlorine must also have been liberated. Where did it go? Surely a week was enough time for it to saturate the acid in that tube? Further, how is it that the water does not also split up, giving, with the acid, three volumes of hydrogen to one of oxygen and one of chlorine?

Technicus.

ALDEBARAN: CORRECTION.

[43072.]—In my letter 43018, page 314, line 4 from below, please read 3¾in. Gregorian," instead of "3¼in. Gregorian." **C. H. Stielow.**

The output of coal in India has increased from 2,562,000 tons in 1894 to 4,569,000 tons in 1898. Of this amount the railway companies consumed 1,452,000 tons.

Pyro Stains on the Hands.—Pyrogallic acid is still mostly used for development. The objection most people have to it is that it stains their hands. This to a great extent is their own fault, as it may easily be prevented by wearing some of the thin guttapercha finger-stalls now on the market. If before developing the fingers are well rubbed all over with vaseline it will prevent the pyro, or any other chemical, soaking into the flesh. A pair of old gloves is another good preventive, but it takes some time to get used to them, as they feel clumsy at first. A duster should be kept handy while developing, to wipe the hands on and prevent the pyro soaking in. This will to a certain extent prevent staining. If there happens by any chance to be stains on the hands they may easily be removed by making a 10 per cent. solution of sulphuric acid, dipping a piece of cotton-wool in it, and well rubbing the stains. The hands must be examined before using the above solution to see that there is no cuts on them, as the acid will make them smart. —O. T., in *Photographic News*

REPLIES TO QUERIES.

*** *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[96577.]—**Seltzogene.**—Possibly a cement like this will do. Dissolve five or six bits of gum elastic, size of large or small pea, in as much spirits of wine as will render it liquid. Separately. Dissolve as much isinglass (previously softened in water, though none of the water to be used) in rum or other spirit, to make 2oz. phial of very strong glue, adding two small pieces of gum ammoniacum, rubbed or ground till dissolved, then mix whole with heat. Keep in phial closely stoppered, and when wanted set the phial in boiling water—is said to stick glass to polished steel. Regent's Park.

[96583.]—**Tips.**—Soak pulverised gum shellac in ten times its weight of strong ammonia, when a slimy mass is obtained, which in three or four weeks will become liquid without the use of hot water. This softens the rubber, and becomes, after volatilisation of the ammonia, hard and impermeable, and sticks rubber to wood or metal.

Regent's Park.

[96597.]—**Paint for Hot-Water Cisterns.**—Clean metal with turpentine or benzine. Put on two coats of mixture of white-lead, spirits of turpentine, and carriage varnish. Follow immediately with a thick coat of carriage varnish and white-lead. Regent's Park.

[96712.]—**Lantern Slides.**—In my reply on p. 322, for "detected" read detached.

Earlsfield, S.W. Silverplume.

[96765.]—**Bagatelle.**—The player who wins the lead takes the nine balls and plays them one after the other up the table from baulk, first striking at the red ball which is placed on the spot about 1ft. below the first hole (see *Enc. Britt.* Vol. III)

Regent's Park.

[96856.]—**Emery Wheels.**—This report of a committee must have been misunderstood, or there is something wrong about it; for emery wheels are not made with shellac or indiarubber. The idea of using corundum as a "substitute" for emery is rich: it is practically the same thing. Not having seen the report of the committee, I cannot say what the passage quoted means; but, judging from similar reports that I have seen, I should say that probably the committee did not understand the subject. The best emery wheels are made with cement, and are moulded under high pressure.

C. M.

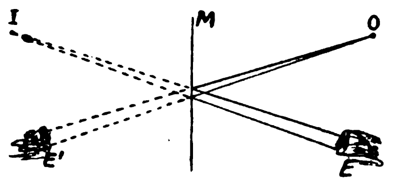
[96857.]—**Test for a Diamond.**—I am much obliged to "Regent's Park" for kindly noticing my query on this subject; but, unfortunately, his reply on p. 236 has nothing whatever to do with my query, which is plainly stated on p. 215. Will some reader who has a little knowledge of the subject read my query, and give some explanation, if possible? I am doubtful if the "dot" method of testing is of any use at all. Dubitans.

[96858.]—**Doublets.**—The simplest way of detecting a doublet is to place it face down on the back of the hand, and observe the light through it—if possible. The difference of refraction in the two stones is sufficient to detect the "doublet." A little experience may be necessary, but that is soon acquired. The reply on p. 236 seems to have been written by someone who is in a bit of a fog.

Sinjins-square.

[96871.]—**Image in Mirror.**—If Mr. Ewer had read my reply to this question in No. 1804, I think he would not have made use of several of the statements which appear in his reply to the same query. He states the fact, that if an object be placed on a mirror and viewed through a telescope from such a position, that the sun's reflected rays are also received by the telescope; if the paper be focussed sharp the sun is out of focus, and, conversely, if the sun be in focus the paper is seen as a blurred image. From this fact he draws two conclusions: First, that there is no image on the glass, and second, that there is no image behind the mirror, through the earth and beyond. To the first of these I can only say that I have never come across any statement to the effect that an image is formed on the mirror, and, therefore, do not see the necessity of proving something which must be obvious to anyone who has studied optics. I will now say something with regard to his second conclusion. In my last letter I stated that the image has no actual existence, but is a virtual one. I now give a fuller explanation of the formation of the image. Let M represent a plane mirror, and O an object in front of it. From O rays of light diverge in straight lines in every direction; but it will suffice if we follow the course of two of them. These two divergent rays travel straight until they reach the mirror, when they are reflected, but still continue to have the same divergence with regard to each other that they had previous to reflection. Thus they reach the eye as if they diverged from I, and, as the mind

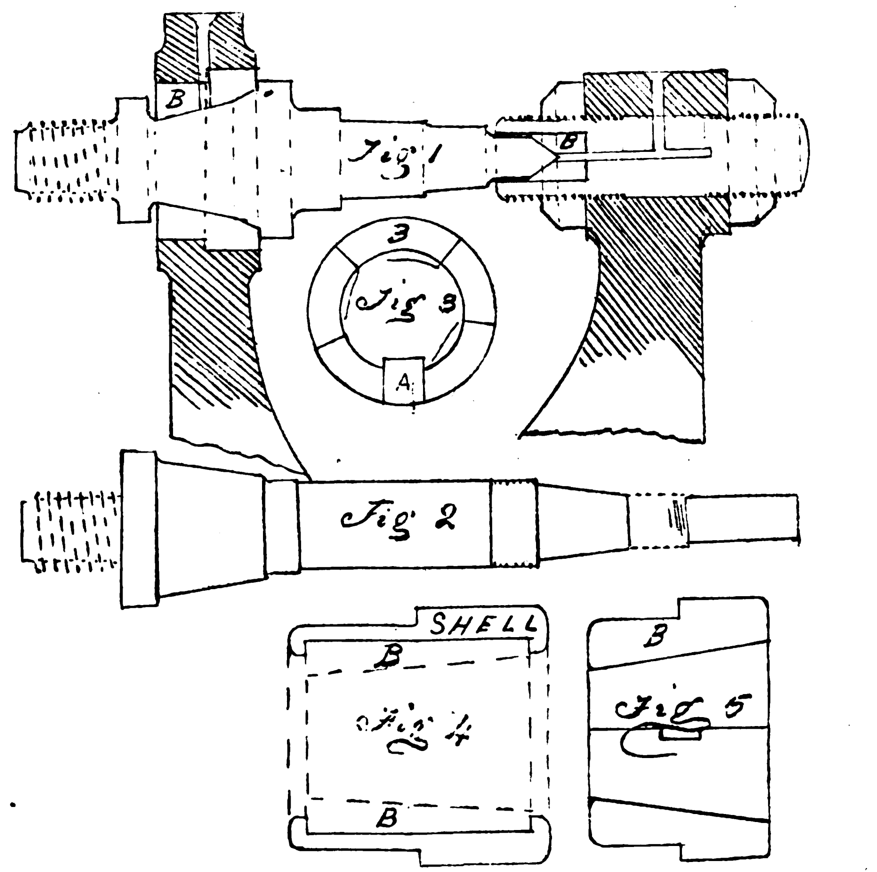
always refers any impression formed on the retina to the place from which the rays appear to come, we see a virtual image at I, which appears to be as far behind the mirror as the object is in front, but which does not really exist at all. The rays enter the observer's eye in precisely the same way that they would do if he placed his eye in the position shown at E[1], that is, as far behind the mirror as he now is in front of it, and removed the mirror so as to view the object direct. The course of the rays would then be as shown by the dotted lines. Mr. Ewer says there is no light outside the eye. Where, then, is it? There is certainly no light inside the eye, except that which enters through the cornea, and where does it come from if not from outside? But, unfortunately for Mr. Ewer's statement, there is light outside the eye. Light is composed of vibrations of luminiferous ether of such frequency as to excite the sense of sight, just the same as heat is composed of vibrations of ether, but slower than those of light. It would be just as reasonable to



say that there is no heat in a fire a mile away, because we cannot feel it, as to say that there is no light because it does not enter the eye and we do not see it. Perhaps Mr. Ewer is confounding light with sight, which is the mental appreciation of external objects by means of visual organs. He says that if the incident and reflected rays make an angle of 60° with each other, and the reflected rays came from a point as far behind the mirror as the object is in front, the angle would be 30°. What angle? An angle of 30° would be formed if the rays from the object went straight through the mirror until they got to a point as far behind as the object is in front, and then turned round and came straight back to the observer's eye, which is absurd. In no other way could they possibly form an angle of 30°, and I have shown above that they do not come from behind the mirror at all, but only appear to do so. With regard to the experiment he suggests of looking through a telescope at a person's eye on which a light is allowed to shine, any image which might be seen in that eye would be seen by reflection from the cornea, and not from the retina, for the reason that under ordinary conditions no light is reflected out of the eye which can enter an observer's eye. This is the reason why we see the pupil as a black spot, and it is only by the aid of the ophthalmoscope that we are able to see the retina. But no such experiment as this is necessary to prove what Mr. Ewer is trying to prove. An inverted image of any external object is formed on the retina in just the same way as it is formed on the screen of the camera. This can be shown to be the case by taking a dead eye and carefully cutting off a portion of the sclerotic at the back of the eye so as to expose the choroid. If it be now directed to an object an inverted image will be seen through the semi-transparent retina. Here again Mr. Ewer seems to be confunding light with sight, for he makes a distinction between an image being formed on the retina and the vibrations reaching the retina, whereas light consists of vibrations, as I have explained above. Undoubtedly it is the vibrations that give nervous impulse to the retina; but there is actually formed an inverted image as in the camera. This, however, bears no relation to the image formed in a plane mirror, because in the eye the image is real, and in the plane mirror it is virtual. C. A. NAYLOR.

[96875.]—**Armour Plating.**—It is not easy to find an explanation of this blunder—for blunder it certainly is. For 1½ mètres it might be possible to suggest that "feet" was meant; but, then, in a technical paper it would more likely be put as 18in. I would suggest that it is an error of the types, and that it should be 12c.m., meaning 12 centimètres. I do not think that any ship has armour thicker than 2ft. A mètre and a half would be close on 5ft.
M. T.

[96886.]—**French Verbs.**—The following taken from Brachet's "Public School French Grammar," would largely contradict "G.'s" answer (p. 300) to "W. B." The imp. is *ais*, &c. in all the conjugations. The Latin 1st conj. imp.—*abam*, became *avam*, then—*auam*, then (as *au* changes to *o*, and *a* to *e*) became O. F. *oe*, as *chantoe*, softened in 11th century into *oie*, as *chantoie*, *chantoit*; 16th century, *oi* became *ouè*, *chantouèt*, soon shortened to *è*, *chantèt*, the same in pronunciation as the present *chantait*. "This change of pronunciation of *oi* into *ai* was not at first expressed by spelling, and Voltaire is the first author who wrote '*chantait*,' &c., adopted by the Academy in 1835. A century before Voltaire, in 1675, Nicolas Berain had already



asked for this reform." Voltaire was thus right, and had very good reason to spell the words as they had come to be pronounced. GOSSIP.

[96935.]—**Motor Cylinder.**—I see in my former answer to the above I have not given enough information to enable you to make a job of the above. You must not use any clamps or carriers to hold the tube, because you cannot do so without distorting it, and when grinding it it gets warm and slips in jumps, and by so doing carries the distortion round with it. You must proceed as follows:—Make your tube hot enough to burn all grease off, and then while hot give it a dressing of good shellac varnish, and roll in or dust it over with some hot floor sand. When cold get about four yards of the jute clothes line; take the strongest strand out, and, twisting it tight, take a dozen turns round your tube, as near equidistant from the ends as you can—i.e., central—and pull as tight as you can, securing both ends, and shellacing the ends. When that is done take the other two strands together, twist tight, and take a dozen turns in the opposite direction, pulling them on as tight as you can. Let thoroughly dry —that is, the shellac on the first coil's ends, put none upon the latter layer. When grinding see that you hold it the right way—that is, the way that will have a tendency to tighten up outer coils. Watch that closely; if you twist it the other way or wriggle it about, you will have to go over it again. Having done the above, you will want nothing but your hands to hold it with, and by so doing you will be enabled to feel your work, and should be able to make a thorough good job of it.
JACK OF ALL TRADES.

[96996.]—**Bone Bearings.**—There is no preparation necessary for ordinary small bearings, but just select your marrow-bone or shank-bone. But if you cannot get the size you require, then put your bones into a good quantity of water, so that the fat will float off them. Let get cold, then take out and dry in some sawdust, or wipe them dry, and place them in a box full of dry ashes—clean ashes from under the grate—and put them in a warm dry place until they are thoroughly dry. If you are going to make a lathe with a tale pin as Fig. 1 (see sketch, Fig. 1), B, bush and back centred in bone, B. If the other at Fig. 2, and you have to build bush for large cone (see Fig. 3), segments of bone fitted upon a piece of wood with glue, gelatine, or isinglass. Any unequal pieces will do—never mind about shape inside. File the wood down, and fit a key-piece, A, in. When dry, turn up true upon the outside. Make a shell like Fig. 4 out of a gas-socket; turn bone down the length, then take off the wood and rebuild inside the shell, putting the key in and driving it home; then chuck true, and bore out for cone; then you can put cone on and true up upon mandrel. The mandrel should be turned up in dead centre, and the bush finished upon the same if it is a flat shank bone. These run a great width. Sometimes they are semi-elliptic on one side. Then take two pieces and fit together, as Fig. 5, with glue, and bore and turn as for Fig. 1. I fitted a lathe, 6in., up for a millwright in the "forties" like that with a steel bush, bored the head-stocks out under a drill press with a crank brace; made a couple of brackets out of a piece of old waggon tires, and my two centres was a pair of old bedstead screws case-hardened; these were fixed upon a plank mounted upon a couple of posts; an old dilapidated waggon-wheel, plugged up, and stuck to a post with a large-headed pin; another pin driven into the nave for my crank, with a rough piece of elm driven upon my job for a pulley. I did all my turning between these dead-centres for the job, and it far exceeded my expectations or the party that I made it for. Fitted the same as Fig. 1, and bush as at Fig. 5. If you have to build your bushes, you must get rid of the grease. There is nothing to equal it, for it is everlasting and clean. There is no case-hardening required. The bearings must be got up true and well burnished. No fear of your bearing being galled. If pulled up, the slightest drop of oil and you are off again. No trouble.
JACK OF ALL TRADES.

[97010.]—**Spectroscope.**—The missing part is an ordinary telescope. You can easily get one, and, having focussed it on some distant object (the moon is handy at night), put the object-glass on the open end of your spectroscope, and look through the prisms and collimator. It is essential that the sharp edge at the end of the set of prisms should be parallel with the slit. I shall be pleased to give any information if "E. S." will state what. The aperture in the collimator tube is, I expect, merely a stop to prevent stray light getting into the telescope.
GEO. W. COBHAM.

[97012.] — **Accumulators.** — If of the pasted grid type, these might be safely discharged at 29 ampères for five or six hours. The sp.gr. of the electrolyte when mixed should be 1·185. Note that when first put into the cells it will fall to 1·150 or thereabouts, and then rise to about 1·200 at full charge. It is very detrimental to the plates to use acid of too low or too high specific gravity.
A. H. AVERY, A.Inst.E.E.
Fulmen Works, Tunbridge Wells.

[97021.]—**Bromide Printing.**—I should like to add a few words to replies on p. 323. "Expose fully" and similar expressions are too vague to help a beginner very much. The usual rule for contact work is: 4sec. at 18in. from an ordinary old-fashioned fishtail gas-burner. But with up-to-date burners a better effect is got at 2½ft. to 3ft., with a minimum exposure of 5sec., and an average of 10sec. to 15sec. Length of exposure depends on force of light and sensity of negative, and the exact exposure in any particular case can only be settled by experiment. Always work by

seconds, with your watch in front of you, and do not be tempted into "counting ten," and that sort of thing. Before development thoroughly wet paper with clean water and examine for bubbles. Flood on the developer from a measure, well rocking dish at the same time. When development is complete, pour off the developer and thoroughly wash, and then fix for ten minutes. Developer given on page 323 may be used indefinitely if carefully filtered into a stoppered bottle after use, and refreshed when using again with about 1 part in 5 of fresh developer. A clean workman has very rarely need of ferrocyanide or or other fakement. H. H. S.

[97034.] — **Trellis.** — The wind pressure is practically the same when open as when closed, but when open your trellis will be weaker as the wind gets more leverage on the supports. No; upon second thoughts there will be more pressure when open, as the total surface to the wind is then nearly doubled. GEO. W. COBHAM.

[97034.]—**Trellis.**—If "O. J. L." will reverse the conditions, and try to fan himself with a gridiron, he will get a practical answer to his question. WIMBORNE CRICKET.

[97036.] — **The Planets.** — What "positions" are required? If the "heliocentric," they will be found in the *Nautical Almanac*, if the "geocentric," in "Raphael's Ephemeris of the Planets' Places," 1s. each year. If the latter, and not obtainable, I can furnish querist with any "position" and date for the present century which he may particularly require. TEMPUS.

[97049.]—**Ohm's Law and the Decrease of Voltage.**—One cannot help being rather amused at Mr. J. Brown's decided expression of opinion. Poor Ohm! If he were in the land of the living no doubt he would instantly retract his iniquitous formula, and apologise for its shameless inaccuracy, after being subjected to such wholesale condemnation from a master mind. Can it be, however, that the querist has not quite grasped the fact that some of the energy which is being transmitted, say, along a line wire must be expended in overcoming the resistance of that wire, and since the current is a constant value throughout its length, it consequently must be at the expense of the volts. Otherwise how could there be a potential difference of say 100 volts between the two terminals of a dynamo with a closed circuit or battery? If there were no volts lost in the circuit there would be no potential difference between any two points, and current would not flow. A. H. AVERY, A.Inst.E.E.
Fulmen Works, Tunbridge Wells.

[97053.]—**Carbon Paper.**—Melt lard 10 parts, wax 1 part; mix with sufficient of fine lampblack. Saturate unglazed paper with this, remove excess, and press. REGENT'S PARK.

[97057.]—**Leaking Coil.**—To MR. BOTTONE.—If your coil is giving ⅜in. spark with three cells, it is working fairly, and it is doubtful whether, if you have not had considerable experience in coil-winding, and especially in coil insulating, you could better it much. Still, if you like to try, you may use two layers of No. 16 double silk-covered wire for the primary, and about 1¼lb. No. 38 best silk-covered for the secondary. If nicely wound, and especially if the secondary is carefully insulated from the primary, you should get 1in. spark easily. S. BOTTONE.

[97060.]—**Alpha Orionis.**—In the 1897 edition of Ball's "Story of the Heavens," it says: "The leading star in Orion is known either as α Orionis or as Betelgeuse." There is no mention of it being the brightest. In Smyth's "Cycle of Celestial Objects" we have the following relating to α Orionis:—"'H.' pointed out this fine star as being variable and periodic. On his star-list the maximum was stated as above β Orionis, the minimum below α Tauri. Fletcher, in 1852, confirmed Herschel; but Schmidt pronounces strongly against the idea of variability." In a selection of variable stars from Dr. Chandler's catalogue, α Orionis is given as ranging in variability from 0·7 to 1·5, and not periodic. W. B. D.

[97060.] — **Alpha Orionis.** — Proctor, in his "Half-hour," says:—"The star α (Betelgeuse) is . . . one of the most remarkable variables in the heavens. It was first observed to be variable by Sir John Herschel in 1836. At this period its variations were most marked and striking. This continued until 1840, when the changes became much less conspicuous. In January, 1849, they had recommenced, and, on Dec. 5, 1852, Mr. Fletcher observed α Orionis brighter than Capella, and actually the largest star in the northern hemisphere. It appears that there is decisive evidence of the presence in this luminary of many elements known to exist in our own sun. . . . Secchi considers that there is evidence of an actual change in the spectrum of the star, an opinion in which Mr. Huggins does not coincide." I have seen Orion myself two or three times lately, when weather permitted, and there is certainly not much difference, if any, between the brightness of the stars α and β. There is, of course, a great difference in the colour of the two stars, and this may account for your seeing Rigel the brighter of the two.
Earlsfield, S.W. SILVERPLUME.

[97060.]—**Alpha Orionis.**—Rigel (β) is certainly, as a general rule, the brightest star in Orion, the Harvard magnitudes of that star and Betelgeuse (α) being 0·32 and 0·91 respectively. Aldebaran (α Tauri) is of magnitude 1·00. Betelgeuse was found to be variable by Sir John Herschel in 1836-40, being at a minimum (below Aldebaran) from 1839, Nov. 26, to 1840, Jan. 7, and then varying little until 1849. Argelander believed it to have a period of 196 days, its light increasing for 91½ days, and falling for 104½ days, this diminution being imperceptible from the 20th to the 70th day after a maximum. "Occasionally its variation is scarcely noticeable," he added. Observations by Schönfeld and Schmidt did not confirm periodicity. On 1852, Dec. 5, Fletcher rated the star brighter than Capella, and nearly as brilliant on 1865, Dec. 25. A well-marked minimum was observed by Gore and others about the middle of December, 1887, when the brightness of Betelgeuse was exactly equal to that of Aldebaran. In the winters of 1890 and 1891 it was generally of magnitude 0·5, and on the whole brighter than in February and March, 1889 (Markwick). In 1893, December, and 1894, January, the magnitude was 0·6-0·8; but very fluctuating in 1894, January to March, 1895, January to March, and the following winter, being as low as 1·0 in the middle of March, 1895 (Pereira). My own observations give the following limits:—1897, Jan. 2-3, 0·3; Mar. 3, 0·7; Dec. 20, 0·3; 1898, Oct. 12, 0·8. Betelgeuse is No. 2098 in Chandler's "Third Catalogue of Variable Stars."
WALTER E. BESLEY.
Clapham Common, Nov. 18.

[97062.]—**Tommy Atkins.**—The name Thomas Atkins was at one time printed on a nomination paper in connection with the Army, being a name used simply to show how the form was to be filled up. It has caught on from this fact alone. HANDEL.

[97065.]—**Whitworth Standard.**—To find the size across the flats of a Whitworth nut, take 1½ the diameter of the bolt which it fits, and add ⅛in. For instance, for a ½in. bolt the nut will measure ¾in. + ¼in. + ⅛in. = ⅞in., and the spanner may be $\frac{29}{32}$in. W. EWART GIBSON.

[97066.]—**Observatory Lamp.**—I used to use an ordinary lantern, burning petroleum, and never had any trouble with it. At first I tried colza oil, but one of its objections was that it froze in winter nights. After I had used the lantern with petroleum for some years, I made two batteries of four cells each for bichromate of potash. One battery lighted a low-resistance lamp, and by having two batteries; I always had one sufficiently fresh, not to run one in a long night's work. I made the solution in large quantities now and then, so that I had not much trouble in refilling the cells. Chromic acid could be used now. The advantage of this light over the lantern was its greater convenience in reading the circles, and in drawing or writing, where perfect darkness was required every minute or two. I made a lamp-holder with a switch on it, and could have the holder in my hand or in a pocket. There was another switch at the battery. I wound up the plates whenever I was not using the light for any time. The batteries lasted well. M.

[97072.]—**Rotation of Shell.**—Certainly the shell is usually still rotating. The rotation is slowly stopped by the friction of the air on the shell-case, and the power of rotation is absorbed (or resolved) into heat. If the shell is still rotating when it explodes, each fragment will travel in a direction governed by its paths of projection and rotation caused by the gun, by its path of projection, and possibly rotation caused by the exploding agent, and by the force of the earth's attraction on it. If the exploding agent is lyddite, the action of this will practically swamp all others at any point near the explosion. GEO. W. COBHAM.

[97076.]—**Medical Batteries.**—Before "Lancastrian" entirely discards primary batteries for working the above, I should advise him to try the Gordon-Burnham copper oxide battery as supplied by the Edison-Swan Co., Braulik, and other electrical supply houses. Prof. Gordon's No. 1 (quart size) battery gives 100 ampère hour output, with one charge of elements, at 1 volt per cell, and no action goes on except on a closed working circuit. The internal resistance is very small, hence its usefulness for medical work. I have had two of these cells, coupled in series, working my medical coil for the past eighteen months, and it still works well. I can therefore confidently recommend it for this purpose. VALENTINE HOLMES.

[97076.]—**Medical Batteries.**—You are quite right; wherever batteries can be dispensed with, it is advisable to do so. For this reason I have devised and patented a special form of dynamo for medical use that supplies at will, two forms of current, (A), one continuous and unidirection, from the armature of dynamo direct, the strength of which can be regulated to a nicety by driving slowly or fast, or by tilting the brushes to different positions on the commutator; and (B) an alternate current set up by a coil which forms part and parcel of the winding of the yoke of the dynamo. The whole machine weighs about 15lb., and occupies a space of only 7in. by 7in. by 5in. It can be driven either by a hand wheel, or by power. The coil portion is capable of giving a spark ⅜in. long, equal to about 15,000 volts; the dynamo current being equal to about 15 to 20 volts. I shall be pleased to give fuller details, if you will write direct to—
Wallington, Surrey. S. BOTTONE.

[97078.]—**Acetylene.**—The haze referred to is caused by phosphoric acid, no doubt, owing to the acetylene being impure. There is an article on the "Purification of Acetylene" in last week's "E. M.," which will no doubt help you.
W. EWART GIBSON.

[97079.]—**Wimshurst.**—The data given are not sufficient for me to be able to diagnose the complaint or locate the fault. There is no doubt that there is a want of insulation somewhere, but where it is not easy to say. Go over your photos again with good clean methylated spirits applied with a clean diaper (previously rinsed in clean water to remove all soap, and then thoroughly dried). Then varnish the plates carefully with good thick shellac varnish, which you should make yourself by dissolving good shellac in clean methylated spirits. Dry this carefully near a fire—not so near as to crack the plates. Now, have you good well-insulating bottles as Leyden jars? Test these for insulating power by charging them, and noting how long they hold their charge. In a fairly dry room they should retain a charge for a quarter of an hour. If they do not, reject them, and rig up others. Of course, you are aware that to get good long sparks, all the woodwork must be well polished or heavily varnished, and all brasswork highly polished and all snags or roughnesses removed. Paints are fatal. The ball on the "brushing" side of collectors should be twice the size of that on the "star" side. S. BOTTONE.

[97080.]—**Soap.**—I think the following may be of some use to "Embosser":—The materials are (1) pure white tallow (not Russian), (2) caustic soda, (3) filtered rainwater. Quantities for 1cwt. of soap: Tallow 70lb., soda 10lb., water 32lb. Tallow is first melted, care being taken not to let it reach boiling point. Then, having first put the soda into the water and allowed it to remain a few minutes, mix the whole together in the boiler, and stir well for an hour. Lade out into a box lined with common canvas, cool, and cut into bars.
E. B.

[97080.]—**Soap.**—Have not come across exactly what you appear to want, but send you second-best. Transparent Soap: From perfectly dry almond tallow or soft soap reduced to shavings, dissolved in closed vessel in equal weight of rectified spirit, clear portion after a few hours' repose poured into moulds or frames, and after a few weeks' exposure to dry atmosphere pieces are trimmed, &c. May be scented at will; coloured by tincture of archil for red, and yellow by tincture of turmeric or annotta. Does not lather well. Probably powdered steatite or French chalk, mixed with water or other liquid, might suit. REGENT'S PARK.

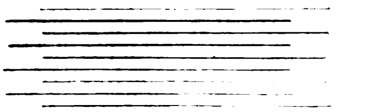
[97081.]—**Strongest Adhesive.**—To MR. BOTTONE OR OTHERS.—I regret that my knowledge does not extend to adhesives. S. BOTTONE.

[97082.]—**Dry Cell.**—To MR. BOTTONE.—(1) Yes. (2) Yes. (3) The Carsak is practically a Leclanché in which the porous cell is replaced by a sack made of canvas or similar coarse material. Procure a wide-mouthed glass jar. Fit it with a cylinder of zinc a trifle smaller. This need not be soldered up the side, nor does it require a bottom. Now make a sack to fit inside the zinc cylinder, of any rather open material, such as canvas, sacking, or even unbleached sheeting. Procure a suitable carbon rod or plate, to stand in the centre of the sack, and fill up with the usual mixture of coarsely-broken graphite and manganese dioxide. Place this inside the zinc cylinder, and fill up the cell with a solution of salammoniac 1 part, water 5 parts.
S. BOTTONE.

[97085.]—**Spark.**—1. With only two pint cells, such a coil would probably not give more than a 1in. spark; but with three quart cells in series, it should give a good 2in. spark. It would not be advisable to exceed this battery-power. 2. The weight of core would be about 2lb. 3. The uranium ammonio fluoride is well known. I have described it in my book on "Radiography." It stands next best to the barium platinocyanide. This salt can be purchased commercially under the name of "Metchebecke's Salts." 4. The seventh edition is now in the publisher's hands, and will probably appear early next year. 5. Because the Wimshurst is so far superior. One with a pair of 12in. plates will easily give 6in. sparks, and never fails to start even in damp weather. S. BOTTONE.

[97083.]—**Quarter-Inch Spark Coil.**—To MR. BOTTONE.—The faults in your coil are several. 1.

You cannot get a decent spark from a coil which has a *solid* core; it must be built up of a number of fine soft iron wires (No. 20 gauge is a good size) drawn out perfectly straight, and cut to the length. 2. The direction of winding of secondary, as regards the winding of primary, has no influence on the result; but if you have reversed the winding of any of the secondary layers, you spoil the coil. 3. The kinks and joins are probably at the bottom of the mischief. Kinks are inadmissible, and these, along with the solid core, account for the failure. If you wrap a condenser round a coil, unless you take extraordinary pains in insulating, you will most likely cause a short circuit to take place. 4. Arrange precisely similar sheets as below, taking care to have a sheet of paraffined paper between



each tinfoil; then roll together all the tinfoils extending beyond the papers at one extremity, and all the others together at the other. S. BOTTONE.

[97084.]—**Imitation Gold and Silver Paint.**—These "paints" are known as Bessemer's, because he was the first to introduce them. They are simply metals very finely ground, and mixed with "varnish"—a copal diluted very much with turpentine. I do not think the powders can be made on the small scale so cheaply as they can be bought (the price per ounce is roughly a shilling, but it varies from 5s. to about 36s. a pound, according to the fineness). There are various shades of gold and copper, but silver is of one tint, though there are some powders which have a greenish tinge. The querist can find full directions in the back volumes; but unless he wants them in cwts. he will find it economical to buy of those who make them by the ton. S. R.

[97086.]—**Dynamo.**—To MR. BOTTONE.—As the coils get hot, it is evident they are taking too much current. Your best plan will be to add on a layer or two of wire, testing after each addition, until you get the machine to run cool. But are you sure the machine was built for the output you state? Perhaps if you wrote to the makers, giving the number of the machine, or a description, they would tell you what it was designed to do. S. BOTTONE.

[97087.]—**Watch Jobbing.**—A watch may go slower in the pocket than when lying on the table from several causes. 1. If it is not well compensated, the heat of the pocket will cause it to go slower than in the cold. But if the watch in question has a compensation balance, a loss from this cause should not amount to many seconds per day. 2. When a watch is in a horizontal position, the balance rests and spins on the end of one pivot only, and there is very little friction. But when the watch is in a vertical position, as in the pocket, the weight of the balance rests upon the sides of two pivots, and the friction is greater, causing the watch to lose. High-class watches have their hair-springs so adjusted as to counteract this tendency to lose; but cheaper watches will often go one minute per day slower in the pocket than lying on a table. F. J. G.

[97088.]—**Motor.**—It would be far better if "Tourvan" used a petrol motor. They are more powerful, have less smell, and easily handled, and petrol can now be obtained at almost any village of importance. 6H.P. would not be sufficient to negotiate a stiff hill (say, 1 in 10) at three miles per hour, especially if the road is in a bad or soft condition. 8H.P., at least, should be used. Could be of assistance to "Tourvan" if he likes to advertise his address, and put himself in communication with— AUTO-CAR ENGINEER.

[97088.]—**Motor.**—I should advise you to purchase back numbers of "E. M.," which contain articles on Oil Motor, prize design Taylor's. Do not on any account put an undersized motor on your cart; you cannot expect a pony to do work of a horse. Have plenty of power. It has been the cry all the time "Not enough power! Sticks on hills, bad roads, and mud!" Put an engine 20B.H.P. on it, and it will be a source of pleasure and use to you. This approximately would come out two cylinders 6½in. dia. by 6in. stroke, run 800 revolutions per minute. See power on all late racing cars used. You will not then be lumbered up with a multiplicity of speed-reducing gears, though you may require one to crawl bad hills. There is little difficulty in getting petrol now in any main town in England, and, with proper forethought, sufficient for run would be carried. It is far better than paraffin for many reasons. MONTY.

[97089.]—**Pneumatic Cover.**—Dissolve solution with naphtha. REGENT'S PARK.

[97093.]—**Motor Cycles.**—You can use phosphor-bronze for cylinder if you like, but I should not recommend it. One or two makers are trying it, though it has long ago been found inferior to cast iron in gas-engine practice. The carbon deposit seems to set on it very hard and quickly—much more so than cast iron—and particles of this deposit will soon score large grooves in cylinder when hot, unless water-jacketed. Nickel or manganese bronze is much to be preferred—and these only when obtained from reliable makers. Gunmetal is not suitable in any form, as the high temperature will sweat the tin out, and leave it rough and porous in a short time. Ball bearings are not satisfactory for any part of the motor which is subjected to sudden shocks. This soon dents up ball-races, owing to bearing only on points; and it is also difficult to get exact adjustment of races. When cold they are too slack, and explosion has bad effect. If you adjust to fit when cold, when warm they are too tight, causing grinding, wear, and hard work. MONTY.

[97093.]—**Motor Cycles.**—If you like you can get the outside made of gunmetal or any of the bronzes; bore out and insert a steel tube. But cast iron is the best material, especially if made of good toughened range metal. This matter should be studied by those who make a speciality of these things. I have some drawings by me—i.e., rough sketches, to perfect, that will open some of your eyes as to building motors presently; but through a series of accidents have been unable to get on. JACK OF ALL TRADES.

[97093.]—**Motor Cycles.**—Phosphor-bronze would do; but, in my opinion, cast iron would be better. Do not try to make cylinders or valves thinner in proportion than dimensions given in recent articles; if you do, trouble will be given when the parts are heated. Ball bearings would do if made very large. I would recommend not less than ⅜in. balls, with large races for about 1in. shaft. The chief objections to them in use are their size and cost. R. J. U.

[97093.]—**Motor Cycles.**—Cast iron is preferable to phosphor-bronze for motor cylinder; it wears much better. The objection to ball-bearings for crankshaft is that, if properly adjusted when motor is cold, they are too tight when it warms up. W. EWART GIBSON.

UNANSWERED QUERIES.

The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered, are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.

QUERIES.

[97094.]—**Dew-cap for Refracting Telescope.**—Will some reader kindly tell me the best material and dimensions for a dew-cap for a 6 n. refractor to be effective in a heavy dew, when the tube and stand literally run with water? F. J. G.

[97095.]—**Photographic Enlarging.**—I have worked for some time with a home-made enlarging apparatus, but only by daylight. I am anxious to continue my work at night, but do not quite know how to begin the construction of a lantern or other source of light, and should be obliged by directions as to burner, reflectors, &c. Also for keeping undue heat from negative. Gas and oil available, electricity out of the question.—H. H. S.

[97096.]—**Amyl Acetate.**—Can anyone inform me whether this substance is soluble in water, whether it is very volatile, whether it will dissolve copal and amber, and what are its principal uses?—PLANTAIN.

[97097.]—**To Sensitise Bromide Paper.**—Will anyone give working formulæ and directions for the sensitising of bromide paper?—H. H. S.

[97098.]—**Adjustment of Newtonian Reflector.**—Suppose the telescope is pointing to the zenith during the daytime; when the flat appears round the reflection of the large mirror is at the bottom of the flat; the image of the flat when adjusted in the centre of the reflection of the large mirror being almost on the lower edge of the flat. When the image of the large mirror is centrally adjusted, the vertical diameter of the flat is less than the horizontal diameter. Will some reader kindly say where the fault is?—W. M. WORSSELL.

[97099.]—**Metal Spinning.**—1. Could Mr. Richard Larsen, who wrote the article on metal spinning in February, 1896, be good enough to let me know if aluminium requires annealing during the process of spinning? And, if so, in what way is the operation performed? 2. How do they obtain that frosted appearance on aluminium? 3. Could Mr. Larsen give full-sized drawings in all sections of the spinning tools, *a*, *b*, and *c*, mentioned in his article? My copy was rather faint, and I cannot make them out. 4. What solder should be used for candlesticks and such articles not intended for cooking?—H. D. CHRISTIAN.

[97100.]—**Lyddite.**—Is there any ferro-cyanide of potassium or other cyanide in lyddite?—F. B. ALLISON, Peasmarsh.

[97101.]—**Acetylene Lamp.**—Is there any way of cleansing the burner of a small portable acetylene lamp without unscrewing the burner, which appears to be choked? The lamp has not been used very much.—C. G. L.

[97102.]—**Speed-Gear.**—To "MONTY."—Some time ago you promised a drawing and particulars of two-speed gear and friction clutch for motor-tricycle. Should be very pleased to see this in the "E. M." Mine is a Beeston motor-tube ignition. Would "Monty" advise the Sims magneto, or the ordinary electric ignition? Can the Editor say when we are going to have the promised articles on the motor-car?—J. H. H.

[97103.]—**Kitchen Boiler.**—Will any of your readers be kind enough to give me information upon the following points? (1) The kitchen-boiler often makes a gurgling noise, which is most annoying, and we have to let some of the hot-water escape. At the instant the tap is opened, instead of water rushing out, a great volume of steam comes forth, and after a time the whole place is nothing but steam. Is this dangerous? And would some kind reader explain the cause of it? (2) And again, when the hot-water tap in the bathroom is opened, upon closing it, the whole of the pipes vibrate most profusely, and make a knocking noise. The knocking can be felt quite distinctly if the hands are rested against any part of the bath; and if the tap be opened it stops. It also stops upon opening the cold-water tap. I am of opinion that it is something to do with the pressure, but know not what. Is this so? If it is anything to do with the pressure, what is the cause of it?—POOCHO.

[97104.]—**Eight-Plate Wimshurst.**—To COL. RICHARDSON AND OTHERS.—Will you kindly say what size sectors should be for this machine? Also what size tube it should work? The plates are glass, 20in. in diameter.—H. M. C., Leeds.

[97105.]—**Bran Tea.**—Can anyone tell me the best way to prepare this? How much bran, say, to a pint or quart of water, and should it be boiled or not? And how to keep the bran back?—BRAN.

[97106.]—**Induction Coil.**—To MR. BOTTONE.—I have made a Wimshurst from the instructions in your book "Radiography," and have obtained good results with it. I am now making the smaller of the two coils described, and should be much obliged if you would tell me what modifications (if any) are necessary to enable it to work a 4in. tube.—A. H.

[97107.]—**Steam.**—Will some reader give me a little information on the following subject? 1. A quantity of water in a boiler is converted into steam, passed through engine into condenser, and thus returned to boiler. When this goes on for some time the quantity of water diminishes. What becomes of it? 2. If a cast-iron vessel containing some water is sealed up air-tight and capable of standing a large inside pressure, and is heated to a great heat, then allowed to cool, will the bulk of water have decreased?—ALEX.

[97108.]—**Cold Glue.**—I should be glad to know of a recipe for a white glue to be used cold.—G. W. B.

[97109.]—**Dynamo.**—How can I find out the correct amount of iron for F.M. and A. in any desired form of dynamo?—E. G. WOODHOUSE.

[97110.]—**Dynamo.**—Will any electrical readers say what output I may expect from a dynamo of these dimensions?—F.M., 3½in. long by ¾in. in thickness, armature tunnel 1⅞in., armature made up of 16-cog drum armature punchings. Also kindly state gauges of wire on F.M. and armature, and what speed. And would a ½H.P. gas-engine be sufficient to drive this?—WOODHOUSE.

[97111.]—**"Norton" Door-Springs.**—I have three doors in my house which are much exposed to strong draughts, and to prevent the banging I have hitherto used "Norton" springs; but these I find, after several years' experience, are unfitted to stand the wear and tear of constant use, and either very quickly get out of order or, as has often happened, are broken in one part or another. I should be glad, therefore, if any reader of the "E.M." could recommend some other form of spring which answers the same purpose as the "Norton"—i.e., that of keeping the door closed, and at the same time preventing it from banging?—N. MACLACHLAN, Rontenbrom, Largs.

[97112.]—**Tin and Sheet Mills.**—Being employed in tin and sheet mills, would someone inform me in your pages if there is a book, not too expensive, that would tell me all about mill-managing, so that I should know how to order bars to be cut and rolled, steel or iron, for either of the mills, and what might the price be? Also if there is a weekly for the above trade, as there is for other trades, such as building, &c., and what is the name of it?—JOE EDWARD.

[97113.]—**Bermaline Bread.**—Would any reader kindly give recipe for making the above?—HOME.

[97114.]—**Telephone.**—I am desirous of constructing a telephone with underground wire from my house to the village, which is about a mile off, and I also wish to be able to communicate with the stables, which is about 100 yards from my house, on the line which the wire will take, and with three other houses, which are 300 yards, 400 yards, and about half a mile respectively from my house, and each about 50 yards on different sides of the line which the wire must take. There is no necessity for the other houses being able to communicate with the village or with each other. I shall be very much obliged for any information as to how this can be most simply and economically accomplished, and as to what the probable expense would be. I should, perhaps, say that there

are local reasons which prevent the use of overhead wires, or of the underground wire following any other line.—E. H. B.

[97115.]—**Dynamo Construction.**—Will any of your readers kindly tell me whether the following particulars for a dynamo are practicable, and whether I can expect to get 110 volts 22 ampères out of it? Manchester type. Shunt wound. Ring armature 9in. long by 7in. diameter, wound with 250 yards No. 11 B.W.G. Field-magnets each 9in. long by 6in. diameter, wound with 6.140 yards No. 16 B.W.G. (i.e., 6,140 yards for the two magnets). Top yoke 2ft. 10in. long by 11in. wide by 1in. thick.—FORWARD.

[97116.]—**Tortoise.**—I have a (Kimberley, S.A.) tortoise that is kept in the kitchen, and has not eaten for five weeks, but remains active, and refuses to settle in a box of dry earth prepared for it. What provision and protection for it should be made for its winter sleep and to keep it alive during winter?—J. A.

[97117.]—**Medical Electricity.**—To MR. BOTTONE.—I have a three-pair plate Wimshurst, 18in. plates, and four Leyden jars. Can I safely use this for medical shocking without endangering life? If I put the spark-gap balls nearly touching each other, and then take a damp string with a sponge at the end from each of the rods carrying the brass balls, could I then use this arrangement with absolute safety, or would you advise using a water regulator?—MEDICAL.

[97118.]—**Cylinder for Oil-Engine.**—Will "Monty" kindly tell me the smallest efficient diameter and stroke of cylinder for an oil-engine using ordinary petroleum to give three or four B.H.P., with pair of flywheels 3ft. diam., 4½in. rim? Also would 1½in. diam. crankshaft be sufficient?—HENRY A. S. UPTON.

[97119.]—**Water Gas.**—Can any reader give me any information as to the most improved method of manufacturing water gas, and what number of thermal units are yielded by combustion of one cubic foot of same?—F. MASON, Electrician.

[97120.]—**To Mr. S. Bottone.**—I want a light for no more than two hours at a time, a 5-candle incandescent lamp. I don't care about the voltage, as I can have any I choose; but I will be most obliged if Mr. Bottone shall kindly suggest what battery and number of cells should be more convenient for my purpose. Impossible for me to use accumulators, because I have no means of recharging them. If the suggested battery is, as probable, a liquid one, what must I do to avoid the spilling of the liquids while carrying about the battery?—HIMOS.

[97121.]—**Geometrical.**—A B is base, C apex, of any triangle A B C. Given P¹ a point in the side A C, find P², a point in the side B C, such that the perpendiculars from P¹ P² on the base A B shall be together equal to the line joining P¹ P².—X.

[97122.]—**Small Motor Winding.**—A small Simplex machine has bipolar armature 1¼in. by 2in., wound open circuit about 2½oz. No. 20 S.W.G. Fields ordinary cast iron, core 1¼in. by 1in., wound 7oz. No. 22 S.W.G. (450 turns). Shunt; massive pole-pieces; small air gap. This machine gives 4 to 5 volts, 3 ampères, as a dynamo, but runs very badly as a motor, taking about 4 volts, 4 ampères, on no load. Would someone kindly state better winding for armature, using same field winding, so as to make machine run well as dynamo or motor? Either shunt or series.—R. W.

[97123.]—**Wireless Telegraphy.**—To MR. BOTTONE.—Would you tell me whether the decoherer, as shown on p. 19 of the "E. M." for Feb. 17, 1899, strikes the glass only when the electrical waves cease, and, if so, why, as the decoherer seems to me to be arranged to act instantly? If this is so, how are dots and dashes distinguished?—RIFLE.

[97124.]—**Medical Coil.**—To MR. BOTTONE.—I have made a medical coil as per your instructions in your book "Electrical Instrument-Making." It is a sliding type. Primary ⅜lb. of No. 24 single-silk-covered. Secondary ⅜lb. of No. 36. Now can I, by making a condenser, get a spark from it of any size-length? If so, how many sheets of tinfoil, and the number of bichromate batteries will it stand? As the coil is now, with two batteries and the wires of the secondary coil about ¹/₃₂in. distance, I can get a spark. Also, can you tell me how to make a dial for the coil to mark the strength?—F. E. A.

[97125.]—**Colouring Metals.**—Would some brother reader kindly inform me how the cases of some watches are coloured black, and some other class of goods in gun-metal coloured something like bright steel?—THOS. J. O'CONNOR.

[97126.]—**Problem.**—Find x from the equation $x^{\frac{1}{3}} + (x-1)^{\frac{1}{3}} = (x+1)^{\frac{1}{3}}$. Professor Chrystal, in his Algebra, gives for the answer—

$$x = \pm \frac{2}{\sqrt{20\sqrt{6} - 45}} \text{ or } \pm \frac{2i}{\sqrt{20\sqrt{6} + 45}}.$$

I cannot succeed in getting this result.—F. OGRAM.

[97127.]—**To Electricians.**—Will some electrician kindly tell me whether the acid used in accumulators is the pure sulphuric acid, or is it the commercial (oil of vitriol)? And I should be very grateful if someone would answer my query—Pasting Accumulator Plates (96912), which appeared on p. 238.—P. A. S.

[97128.]—**Rate of Interest.**—Will someone kindly show, in a simple and easy manner, how the following calculations may be made? I buy a 4 per cent. security at the price of 108, carrying £1 10s. of accrued interest. It is redeemable at par in 10 years. What rate of interest does this investment yield?—not approximate, but strictly accurate, taking into account that the premium (£8) is deducted in one sum at the end of the term (10 years).—CHERCHEUR.

[97129.]—**Wheeled Carriages.**—I have been told that a three-wheeled carriage is more stable than a four-wheeled one. Is this so? And, if so, why? I am also informed that a four-wheeled carriage with a long narrow wheel-base is more stable than one with a short wide wheel-base. This is opposite to what obtains in boats. Why? Finally, is a car with small wheels more stable than one with large wheels, if the centre of gravity is the same height in each case?—MOTOR CAR.

[97130.]—**Drawing Wire.**—Will some reader advise me what sort of steel I am to get for making dies for drawing wire that will stand a great pressure, and will not chip or wear in a short time, and what is the best method of hardening steel for this purpose? I have tried best tool steel, and find it wears and chips in a very short time. Or can you tell me if steel is used for this purpose? If not, what is used, as it is to be drawn uniform size?—C. A. FAULKENER.

ANSWERS TO CORRESPONDENTS.

⁂ *All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries, put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

⁂ Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

The following are the initials, &c., of letters to hand up to Wednesday evening, Nov. 22, and unacknowledged elsewhere:—

ERG.—Alex. Smith.—Hugh Alexander.—Lightning.—A Fellow of the Royal Astronomical Society.—Rex.—H. H. S., Paris.—F. H. Wenham.—Coherer.—Carton.—J. M. S. P.—J. E. Gore.—Try Again.—H. Lattey.—A Reader.—M. S. Don.—Algol.—Alex. Reith, M.D.—A. R.

J. B. CLIVE.—The query was published on p. 98. The title and number were given on p. 237, and again on p. 325. It is not unlikely that readers did not understand it, and so did not reply. An alloy of lead and antimony is readily covered with a film of copper, and then it is easy to cover that with a wash of silver. For "good work" it will be necessary, probably, to use a battery. See many replies in back volumes, or text-books of electro-metallurgy.

APPRENTICE.—Query seems to be wrong. As to a sanitary inspector, procure the publications of the Sanitary Institute, Margaret-street, W. A "clerk of the works" is a man with technical knowledge, who is competent to pass an examination in Building Construction. They are altogether different "lines."

R. W.—We have not heard of their publication in book form.

MAC.—Probably the village blacksmith or a travelling tinker can convert your copper coal-scuttle into an ornamental flower-pot. As to the "expense," that will depend on the condition of the scuttle, and on the amount of work to be expended on it.

W. R. PIDGEON.—To what does your letter of Nov. 14 refer?

P. H.—There are vacancies for engine-room artificers, but we do not know what the "test job" is. That would be kept secret until the candidate was asked to perform it. If you can pass as a "fitter" or a "turner," you would no doubt be accepted—especially at the present time.

JAMES PARIS.—We cannot find space for discussion between customers and advertisers as to quality of goods supplied. Nor can we accept any responsibility in such cases. Where fraud is evident, as in the case of money being received and no goods sent, we do our best to see readers righted; but disputes as to quality or value must be settled in the ordinary way. Your remedy is to sue the advertiser for the return of your money if the lathe, in your opinion, does not warrant its description. By the way, there is *no* such advt. as you refer to on p. vi. No. 1,801, in the position you indicate, or we might possibly have been able to form some opinion as to the character and standing of the advertiser.

O. TOM OBILE.—The correspondent you mentioned subsequently qualified his offer by a suggestion inviting private correspondence, which we did not insert, having reason to apprehend that he sought his own personal advantage rather than that of correspondents he offered to help.

F. W. E.—It produces the sounds that are mechanically imprinted on the cylinder: but as to how long the materials will last there is no information. The articles on the Grammaphone commenced in No. 1779, April 28, 1899. See the numerous replies on the subject: some instruments appear to be better than others. Obviously the sounds of a solo are reproduced more accurately than those of a band or an orchestra.

HOPEFUL.—All in good time; they will begin shortly. For one thing the author has been on his honeymoon trip, and, besides, we have the series now appearing to finish first.

H. T.—We do not think the immediate future of the brickmaking trade is likely to be a prosperous one, and should recommend you *not* to take shares in the company you name.

OXFORD.—Sorry, but we cannot make out your sketch, and correspondents must please observe our rules above, if they expect their communications to appear.

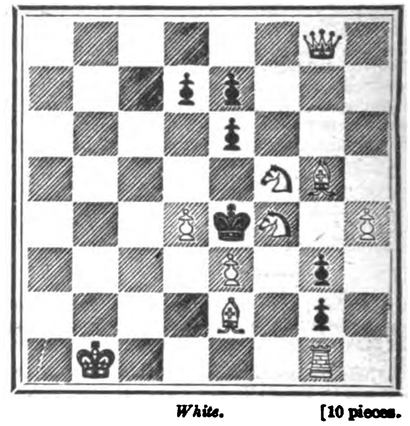
IN TYPE.—Alex. Smith, T. G. P.

CHESS.

All communications for this column to be addressed to The CHESS EDITOR, at the Office, 332, Strand.

PROBLEM No. 1702.—By L. HAWKINS.

Black. [6 pieces.



White. [10 pieces.

White to play and mate in two moves.

(*Solutions should reach us not later than Dec. 4.*)

Solution of PROBLEM No. 1700.—By H. V. GOTTSCHALL.

Key-move, B-K 5.

NOTICES TO CORRESPONDENTS.

PROBLEM No. 1700.—Correct solution received from J. E. Gore, J. Mason, Richard Inwards, N. M. Munro, A. Tupman, Whin-Hurst, Rev. Dr. Quilter, Quizco, F. B. (Oldham), T. Clark, Wm. Peters, H. B. F., S. Woollen.

H. FELLOWES.—Captn. G. H. Mackenzie was born 24th March, 1837, and died in New York, April 14, 1891. Paul Morphy was born in New Orleans in 1837, and died in 1884.

J. CHIPPERFIELD.—Solutions of No. 1699 and 1700 not correct.

NOTICE TO SUBSCRIBERS.

Home Subscribers receiving their copies direct from the Office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a PINK Wrapper, as an intimation that a fresh remittance is necessary if it is desired to continue their subscription.

Foreign Subscribers will have the Pink Wrapper sent ONE MONTH before expiration, in order to give them time to forward fresh remittance before subscription expires.

The English Mechanic
AND WORLD OF SCIENCE AND ART.
FRIDAY, DECEMBER 1, 1899.

INLAYING.—VIII.

THE next stage of inlaying is termed the "chopping in inlays," so termed because if we desire to enrich the flat surface of any

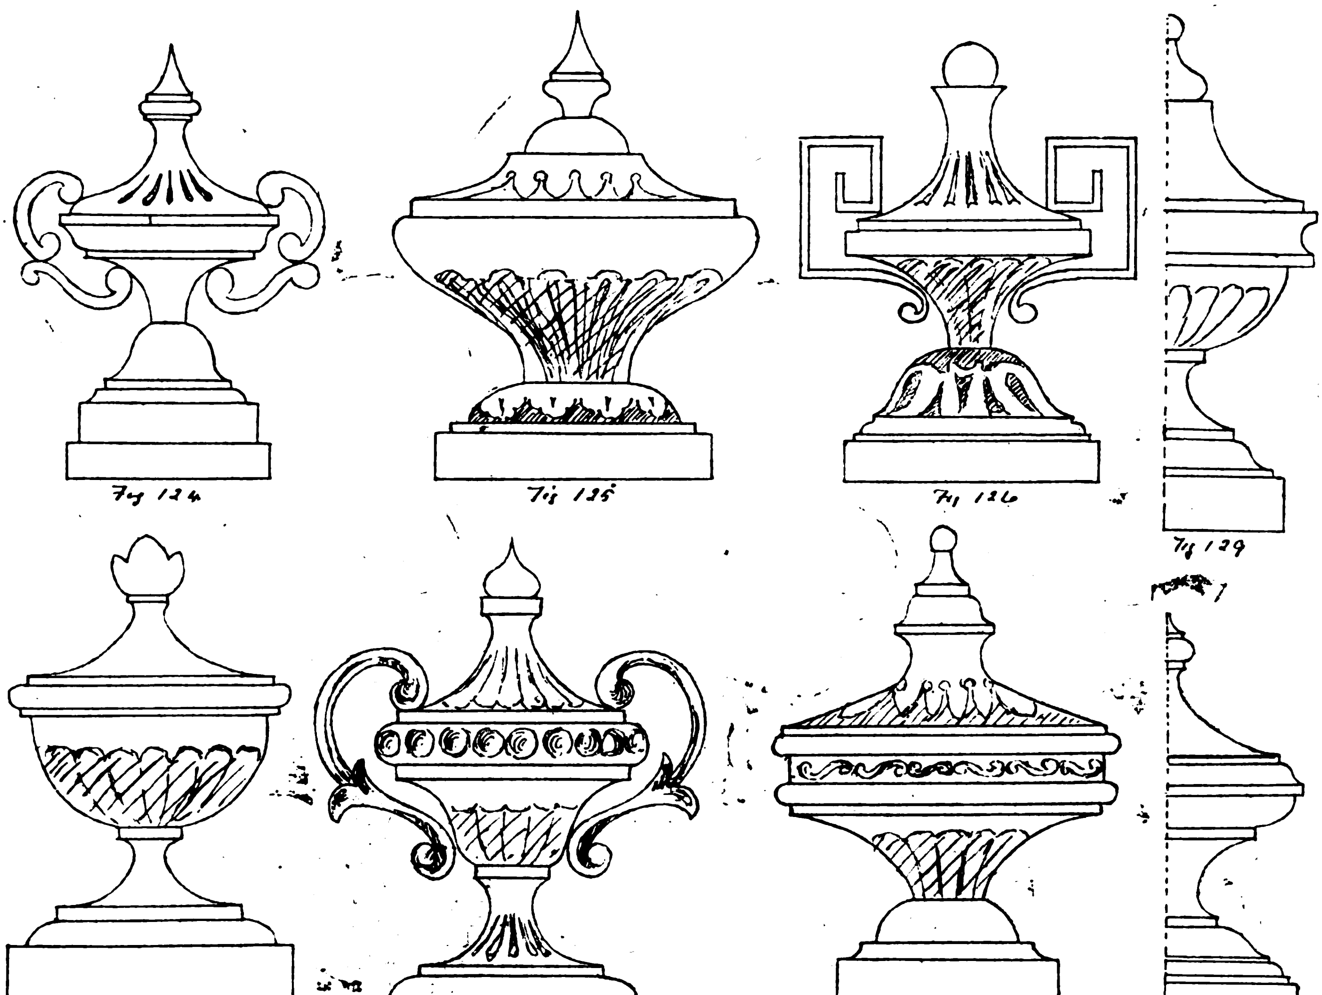


Fig 124 Fig 125 Fig 126 Fig 129 Fig 127 Fig 129 Fig 128 Fig 130

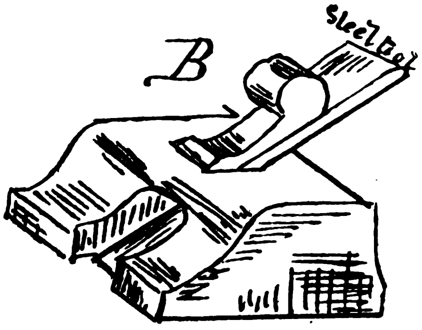
article devoid of any inlay or other ornamentation, then we must "chop" out (or in) a space to take the ornament desired. Figs. 124 to 130 are for the above, and the ornamentation is suggestive.

The ornament, generally of some simple form or outline, is assembled and glued to a fairly stiff paper. When so done the cutting is laid down on the work and marked distinctly with a marking-awl. It now remains to cut away a shallow space, so that when the cutting is laid in all should be flush or level. To assist us in gaining the requisite depth, we employ a tool called an old woman's tooth (see sketch B). The desired end is best gained by working out a partial depth at first, then by tapping the chisel or tooth the depth required can be cleanly and accurately got. The work of cutting the outline is, and must always be, the first step. If of varied and intricate form, a ready access to gouges will materially help. Where the surface is larger than the "tooth block," a narrow strip must be left for the block to rest upon, the removal of which is an after-process. Having successfully cut out the receptacle for the inlay, it remains to glue the latter paper side outwards. All flat work is safer if pressure can be brought to bear upon the caul or warmed piece of flat wood. If hand-screws, cramps, or other tools are not at hand, a spring bar is at once sound and practical. Having the work on a bench or table, and a beam overhead, it is but the work of a few moments to cut a lath, preferably of hickory, or an old string-bow, if strong enough. By springing the same between beam and work, there need not be any fear of unsound work.

The part that will tax the student mostly is in sweep or shaped work. A ready means can be obtained by making a bag and filling the same with either sand or fine sawdust. A piece of zinc will answer the purpose of a caul. It is a question which is best: to warm the sand-bag or the zinc. We in



Old Woman's Tooth

practice bed the bag to fit, and warm the zinc, applying heavy weight where permissible to gain the desired pressure.

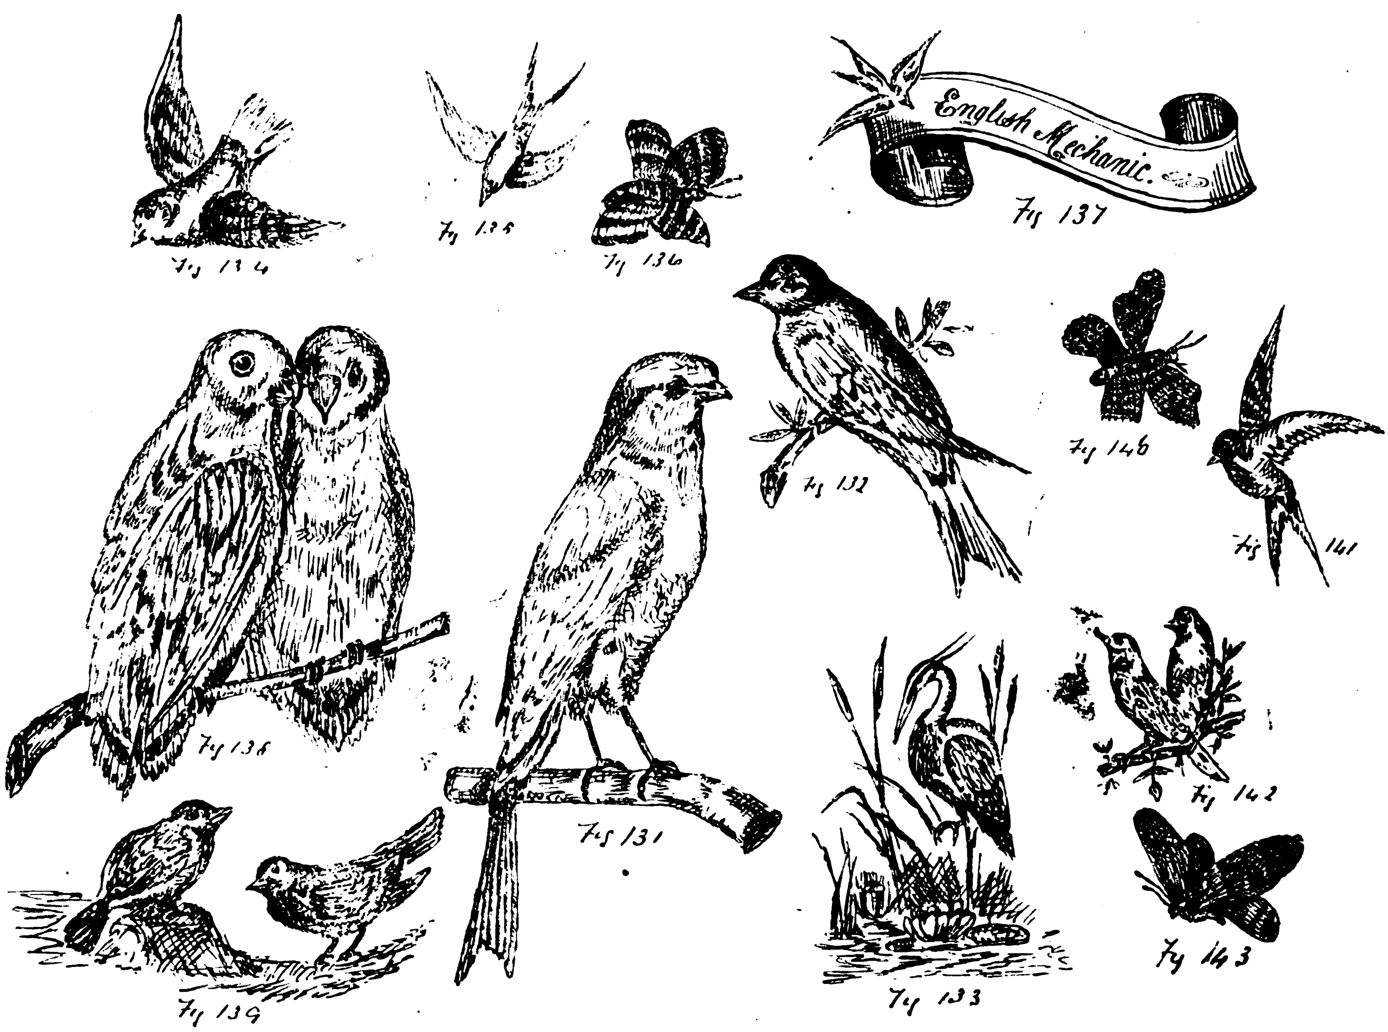
With respect to the bar-work, it must be plain to the merest tiro that the bar, ever endeavouring to regain its straight condition, will tend to force the veneer in that direction, which in this instance is outwards. Therefore it behoves one to set the two ends as near coincidentally as possible (one exactly over the other). In that way, the pressure will be downwards and upwards, or nearly. If that little point is looked to, much trouble will be saved.

Another point is the releasing of the pressure. It should not be too quickly released ere the glue is set, *with the just possibility of the work (cutting) sticking to the veneering caul*, or rising in bulges or blisters; nor should it be left too long, because the glue always oozes through, and may pass the outer paper and adhere to the caul, so that when lifted it may bring away some of the cutting with it; it is for that reason we rub moderately wet soap on the caul before pressing together.

Flat work can well remain under pressure from 10 to 24 hours, with the above precaution of soaping; the work should not be touched under 24 hours, or even more, if convenient; it can then be safely prepared for polishing.

Where wood cauls are used, soaping the surface with a piece of dry soap will prevent it adhering to the work. If zinc is used, a smear of mutton fat will help to the same end, and where the work cannot well be retained in position, a few veneer pins will help to keep all right.

To gain time and lessen the after-work, the surface of the cutting is invariably damped just sufficient to moisten the glue that holds the paper. In nowise must the soaking be prolonged or too hot; therefore, taking it for granted that the cleansing



process has got all surplus glue and paper off, it must be examined carefully to see if all is sound and in perfect contact. If not, then the part must be warmed gently with an iron, afterwards using a caul, as before stated.

We can now follow on with wider stringing or banding. If the groundwork holding the cutting is of a dark nature, such as walnut, rosewood, Coromandel, or any other darker wood, then the relieving band should, for euphony's sake, be gradual; too great a contrast should be avoided. If the ground is walnut, then a band of satinwood, boxwood, or yew, cut across the grain, having a black line each side of the band, and a white ditto outside that, which can be from $^3/_{16}$in. to $^3/_8$in. in width. If the band is rosewood, tulipwood, or kingwood, then a satinwood line, with an outer one of silver-grey as outside bindings. If the banding is of silver-grey, then a black line, with an outer ditto of redwood, will not look amiss. If the ground should be rosewood, either silver-grey, satin, or boxwood can be used in conjunction. Cut either across the grain or lengthwise, with the outer fine line in harmony. There are many more; but it would be superfluous to describe them all. The above should guide as to the making-up. Figs. 146 to 149, which will appear anon, give a narrow band; but they can be made all widths by following instructions.

Birds, &c.

We now approach a task which will demand a fair share of patience. We need not repeat what we have previously stated; but to help as much as possible, we will describe the method of working to obtain the best result. The first example (Figs. 131 or 143) will suffice for the major portion of designs; where even the zigzag exists, it can safely be brought into use. What we mean is, take the upper portion of wing. If cut carefully, the effect will not be lost; but it entails much work. By cutting the upper part of wing, and printing its serrations on to the body portion, a fairly fine joint should be got, and that applies to the collar-ring, and likewise the feathers; but the tail can be cut solid, and engraved up to gain the desired effect. Yet it does not follow that the entire markings cannot be cut; but it would be a work of great patience. The moths and butterflies will not call for much comment; only endeavour to copy the natural object for colour, &c.

We should advise the cutting of the birds to be done in three or four shades of rich brown; the browns can be enriched with the addition of a little cochineal to the brown dye; but do not overdo it. In that way the filling can be of, say, lampblack and glue, and the groundwork either satinwood, silver-grey, or bird's-eye maple. The colours for the moths cannot be too rich, and yet they should not give too great a contrast; otherwise the roundness in natural appearance will be lost. Fig. 133 should be cut in browns, using the darkest tints for the surroundings, so as to throw the bird up in relief as much as possible.

NOTICES OF BOOKS.

A Textbook of Physics. By W. WATSON, A.R.C.S., B.Sc.Lond. London, New York, and Bombay: Longmans, Green, and Co.

THIS work is intended for the use of students already familiar with the elements of the subjects, and is by the assistant professor of physics at the Royal College of Science, London. The principal point the author had in view was the arrangement: the best sequence or the most convenient for teaching. Anything "taken for granted" in any section has been previously explained in a preceding section, instead of postponing the explanation. The author writes from practical experience of the art of teaching, and, as he says, no textbook can take the place of experimentally illustrated lectures and of actual work in the laboratory. Therefore the illustrations are diagrammatic, and the work is really to be read by the student who is attending courses of lectures and classes in a laboratory. Nevertheless, it is an excellent textbook for those who cannot spare the time to attend classes, and we should not be surprised if it becomes a formidable rival to Ganot's "Physics." Some of the illustrations are taken from that famous work, but the majority have been specially prepared. There are 564 figures altogether, and there are nearly 700 pages of text.

Mechanical Movements, Powers, Devices, and Appliances. By GARDNER D. HISCOX, M.E. London: Sampson Low, Marston, and Co., Ltd.

ABOUT thirty years ago a useful work entitled "Five Hundred and Seven Mechanical Movements" was brought out in America, and portions of it were reproduced in our columns in Vol. XI. and subsequent volumes. Such a work is of great assistance to the inventor and to the engineering and mechanical student, and the author of the present work has endeavoured to help the engineer in ideal and practical mechanics in the "true line of research." He has therefore presented the reader with no fewer than 1,649 engravings specially drawn for the work, which illustrate the "movements" themselves, but also show their application in machines actually constructed or patented. Hence his textbook is well adapted to the wants of inventors, mechanics, engineers, draughtsmen, &c., and should find a place in all public libraries and in mechanics' institutes, and in places where science classes are held in all subjects connected with the mechanical arts.

On the Theory and Practice of Art-Enamelling upon Metals. By HENRY CUNYNGHAME, M.A. Westminster: Archibald Constable and Co.

THE author of this work, who is well known as a craftsman of no ordinary skill, says that the development of "modern machinery and of the factory system has produced, among other changes, the practice of making jewellery out of

stamped metal—a practice which has deprived modern work of most of its artistic value." When Mr. Cunynghame first commenced the work of enamelling he found great difficulty in obtaining information, but he pursued his hobby—if we may so call it—and searched far and wide for hints and notes and "secrets," not merely in English publications, but in those of Germany, France, and Italy. Every process he describes has been repeatedly verified practically, and he has tried and suggested some new ones. The earlier pages of the work are devoted to an introduction which is historical, but the remainder are occupied with chapters on the choice of a style in enamelling; the mode of executing "Limoges enamel"; cloisonné enamels, jewellery, and imitation glass gems; and the manufacture of enamel. The practical descriptions of the methods of enamelling are complete, and are amply sufficient to enable any intelligent man to perform the necessary processes, and it is to those workers who are something more than "hands" that this book is addressed. The frontispiece is one of a series of eighteen enamels representing scenes from the life of Christ by J. Pénicaud II., date about 1530, in the South Kensington Museum. It is reproduced in colours; another plate in colours is from the Salting collection. There are many illustrations, and those showing methods of manipulation, &c., will be especially useful to the beginner.

We have also received *Electric Wiring, Fittings, Switches, and Lamps*, by W. Perren Maycock, M.I.E.E. (London: Whittaker and Co.), a practical book for electric-light engineers, and also for students.——*Arc Lamps and How to Maintain Them*, by H. Smithson and E. Sharpe (London: Whittaker and Co.) is a practical handbook for the use of those who have charge of arc lamps.——*Electric Bells and Alarms*, by F. E. Powell (London: Dawbarn and Ward, Ltd.), is a little work which may be useful to those who wish to fit up electric bells and alarms.——*The Story of Eclipses*, by George F. Chambers, F.R.A.S., (London: Geo. Newnes, Ltd.) is a popular account of eclipses, written by one who has all the information to his hand.——*Problems in Machine Design*, by Charles H. Innes, M.A. (Manchester: Technical Publishing Company, Ltd.), is the second edition of a useful work for students preparing for the Honours stage.——*Natural and Artificial Methods of Ventilation* (London: Robert Boyle and Son, Ltd.) is a "compilation," as it professes to be, of the views of experts who have turned their attention to the subject. It is a useful work for the householder who studies the healthy condition of his rooms, and will afford some valuable hints to those interested in the important, but troublesome, matter of ventilation. ——*Key to Engines and Engine-Running*, by Joshua Rose, M.E. (London: Sampson Low, Marston, and Co., Ltd.), is a work that may be found useful by students, for the author has taken much pains to make everything as clear as possible.——*Heat for Advanced Students*, by Edwin Edser (London: Macmillan and Co., Ltd.), is intended for students who are already grounded in the principles of physics. ——*Practical Mathematics*, by John Graham, B.A., B.E. (London: Edward Arnold), is an elementary treatise in which the attempt has been made (successfully) to make the subject a little more practical and interesting.——*Practical Plane and Solid Geometry for Advanced Students*, by Joseph Harrison and G. A. Baxandall (London: Macmillan and Co., Ltd.) is written for the use of science students who are required to give accurate draughtsmanship throughout their work.——*Practical Geometry for Science and Art Students*, by John Carroll (London: Burns and Oates), is the 39th edition of a well-known work.——*Experimental Science*, by R. A. Gregory and A. T. Simmons, B.Sc. Lond. (London: Macmillan and Co., Ltd.), is a useful work for students, as the authors recognise that its merits, whatever they may be, are due to the plan of construction.——*Building Construction for Beginners*, by J. W. Riley (London: Macmillan and Co., Ltd.), is an elementary work well adapted for its purpose, as there are plenty of illustrations.——*Dissected Model of a Direct-Current Dynamo*, by Arnold Philip (London: George Philip and Son), is a method of instructing the reader in the construction of a dynamo by means of coloured plates which overlap, and have the parts numbered the same, descriptive matter being furnished. It is a useful method of teaching.

SOME METEOROLOGICAL INSTRUMENTS AND THEIR USES.—VIII.

It is a question among meteorologists as to whether the spectroscope is or is not of any assistance in forecasting the weather. As applied to meteorology this instrument is chiefly used for investigating the so-called rainband, and since it is considered to offer a means of arriving at a solution of the problems of the weather by pointing out, as it were, a short cut, it has always enjoyed a certain amount of popularity. But the short cuts pointed out to meteorologists are many, and some have an astronomical basis and suggest that the changes in the sun and the moon or one of the planets synchronise with alterations in the weather; while at other times the secrets of sunshine and storm are said to be revealed by studying the vagaries of terrestrial and atmospheric electricity. None of these suggestions, although it may have the truth of the matter in it, stands the test of being actually employed in the work of preparing a daily weather forecast. It is but fair, however, to observe that many of these ideas have not had a proper opportunity of demonstrating their worth, for it is only by daily experiments and tests over a lengthened period that the value of any meteorological novelty can be discovered. The rainband spectroscope is one such idea which may be said never to have had a fair trial, for, owing to certain difficulties of manipulation, those observers who have procured these instruments, either at their own expense or who may have had them supplied to them from a Government office, have been discouraged by their lack of success in using them, and have pronounced them of no utility. Seeing, however, that other observers have claimed a large percentage of success in estimating the degree of moisture in the air by means of the spectroscope, there is encouragement to persevere a little longer along this line of meteorological research. So far as can be judged at present, it would appear to be impossible to foretell the weather by observing only a single phenomenon, and it is only when numerous observations are combined that a weather prophet can hope for even a moderate success in his predictions. If, therefore, the rainband spectroscope is not asked to read right off, so to speak, the sphinx riddle of the weather, but is merely required to supplement records obtained by other means, it ought to prove a useful adjunct to the meteorological armoury.

The rainband is principally found in the red, orange, and yellow portion of the atmospheric spectrum, and the intensity of the lines composing the band is said to vary according to the amount of vapour in the air. As a rule, rainband spectroscopists confine their attention to the group of lines which are to be found on the red side of the D line, and although there are other portions of the spectrum which are considered to change their appearance with the alterations in the atmospheric humidity, it is the former lines which receive the most notice. Now, it need hardly be said that these lines have received special attention in some of the principal meteorological observatories, the spectroscopes employed for this purpose being fitted with elaborate appliances for measuring the rainband; and it is also well known that there are smaller and more compact spectroscopes, such as can be used by the ordinary observer. These latter instruments are about 2in. long and ½in. or so in diameter, and there is at one end a milled head which regulates the breath of a small slit formed of two pieces of brass placed parallel to one another. Inside the tube which carries the slit is another tube closed by a lens, the other end being protected by a thin disc of glass. The inner tube it is which holds the series of prisms, which are, of course, the most important part of the instrument. The apparatus therefore for studying the rainband may easily be carried in the pocket, and is always at hand when it is desired to make an observation.

By using a direct-vision spectroscope the rainband is split up into many hundreds of lines, and one investigator, by employing a fine spider thread or platinum wire fixed in a movable frame, has succeeded in obtaining some very refined measurements. To measure the more important portions of the rainband the wire is moved slightly out of focus, so that its image becomes less distinct as the distance increases, and in making an observation a micrometer screw is manipulated until the image of the wire is as intense as that of the principal line in the rainband. A number on the divided head of the screw then indicates the degree of visibility or intensity. By means of this arrangement the observer to whom the credit of this method of measuring the rainband is due, has been able to differentiate some thirty or forty different shades in the lines, and some interesting observations have been made at different seasons of the year and at different altitudes above the horizon. No such detail as the foregoing is, however, possible with a pocket spectroscope, and, indeed, with these instruments the observer has to detect changes in shading which occur in a band of colour which is but an inch long and only half an inch broad. At best also the rain-band in these instruments appears but as a burr or shadow, and, unlike the larger spectroscopes mentioned above, there is no definite standard to which their indications may be referred, so that the measurements or estimates are made with a mental scale which depends for its consistency upon the ability of the observer, and which, moreover, changes with his mental moods from day to day.

Some observers adopt a scale in which 1 represents a faint rainband and 10 a strong. Seeing, however, that the intensity of the band changes with passing clouds, it has been found somewhat difficult to determine the approximate value of any given intensity, and many observers have accordingly employed a scale which only ranges from 1 to 5, and these five values are probably as many as can usefully be recorded. But before the attempt is made to use either one or the other of these scales the rainband has to be focussed in the spectroscope, and this is an operation in which all observers are not equally successful. Some never succeed in seeing it at all, and they are therefore ready to agree with the facetious remark once made to the effect that the rainband was an optical delusion strengthened by long practice. A wise man, however, once observed that the eye sees what it brings with it the power of seeing; and as regards the use of a rainband spectroscope, a little training and the exercise of a few simple precautions are necessary to secure the best results. In the first place, it is important to keep the spectroscope clean, and the prisms, lens, and slit need constant attention to keep them free from dust, for dust will produce appearances in the spectrum which, by the unwary, are often taken for the rainband. A camel's-hair brush will be found effective in keeping the slit free from intruding and vitiating dusty particles.

In making an observation, it is not necessary to point the spectroscope towards the sun, and all that is required is that it be directed towards some portion of the sky that is free from cloud, preference being given, as a general rule, to some quarter in the north or north-west. Supposing the observer has plenty of time at his disposal, it is recommended that he examine the sky from the zenith down to the horizon. Many observers are content with making only one observation; but experience indicates that two at least should be made. If no more than two are possible, they should be made at the horizon and at 45° above it. At all times there is a danger in taking observations simply at the horizon lest a rainband produced by columns of vapour rising from the surface of the earth should be taken for the effect produced by rain-clouds, and while the amount of vapour at all levels plays an important part in the condensation of rain it is well to investigate the atmosphere at distances above these low-lying bands of vapour. In addition, therefore, to directing the spectroscope towards the horizon many observers examine the atmosphere at 45° above this point, and at each observation they further use a scale which ranges from 1 to 5. The sum, therefore, of the two readings gives the value of the observation as compared with a scale in which the maximum intensity of the rainband is represented by 10. By thus taking the observations in two portions the difficulties of estimating the values of the band are considerably lessened.

As regards determining what is to repesent the maximum value of the scale, this can only be discovered by experiment, and it may be fixed by directing the spectroscope to the western sky at sunset when the rays of light are passing through a great depth of vapour, or it may be determined by looking at the sky on some occasion when a heavy downpour of rain is imminent. In focussing the spectroscope, the shadow or burr to the red side of the D line is, of course, the main feature for examination; but this portion of the spectrum is often made more distinct if such lines, for

instance, as those known as E and *b* in the green area are clearly focussed. Many people who have invested in these pocket spectroscopes appear to think that the chief aim is to get the colours of the spectrum as brilliant as possible; but in actual practice the colours should be rather subdued and the lines among them made as black as possible. Moreover, before making the daily observation it is advisable to focus the spectroscope at a point about 20° above the horizon, and then, having primed the instrument, as it were, at this elevation, its indications will not be far wrong either for the subsequent observation at the horizon or at 45° altitude. Assistance in examining the variations in the spectrum will be rendered by shading the eyes with the hand, and if the observer does not object to having a charge for eccentricity brought against him by his neighbours, he will add to the accuracy of his records if he imitates the action of the photographer and surveys the heavens with his head shaded by a black cloth. Seeing, however, that the early morning hours, say, 7 a.m. or 8 a.m., are the most suitable for making these rainband investigations, the observer may probably defy personal criticism.

The hope of those meteorologists who use these spectroscopes is that their utility as hygrometers may be demonstrated. A hygrometer such as that, for instance, formed by combining the familiar dry-bulb and wet-bulb thermometers is commonly erected in a screen some 4ft. or so above the ground, and the indications of such a hygrometer, therefore, merely refer to a very small portion of the atmosphere, and tell next to nothing of the hygrometric condition of the strata of air overhead. Supposing, however, the hygrospectroscope, as these instruments are sometimes called, could be developed into an instrument of precision, the atmosphere could be explored at all heights, and the rate of increase in the amount of moisture from the horizon to the zenith be discovered. When the spectroscope indicates that the intensity of the rainband decreases but little from the horizon up to an altitude of 45°, it is said that there is reason for supposing much vapour to be present, and when there is no decrease right up to the zenith a heavy downpour of rain may be prophesied with confidence. In passing, it may perhaps be noted that observations made with the hygrospectroscope in balloons indicate that the rainband grows fainter as the height above the earth increases; and at 20,000ft. it disappears altogether, these observations being corroborated by the investigations made with the aid of this instrument at the top of Ben Nevis. It is, therefore, from its supposed ability to sum up the aqueous condition of the atmosphere as a whole that the spectroscope gains its superiority over the hygrometers, and although during many years it was considered to be nothing more than a scientific toy, it must always be of interest, as being an attempt to record the meteorological conditions existing in the upper regions of the air. But, as already indicated when writing in previous articles concerning the different processes at work in forming the clouds, there are many other things besides aqueous vapour which help to produce rain. The spectroscope tells nothing, for instance, about the alterations in temperature, pressure, and electrical potential, and movements of the vapour-laden air, and at best it gives information concerning only one factor in the problem. It is because of the incomplete information provided by the hygrospectroscope that it sometimes fails as a weather prognostic, so that even when it indicates much aqueous vapour a wise prophet will not forecast rain unless his other instruments tell him that the conditions are favourable for its condensation. The rainband spectroscope should not, therefore, be expected to clear the difficulties from the path of the meteorologist without other support, for at present it is but a comparatively undisciplined auxiliary, and has yet to demonstrate its worth.

ORNAMENTAL TURNING.—XXXI.

By J. H. Evans.

I LEFT off in my last at a very interesting point in the construction of the spherical slide-rest, viz., the making of the tangent screw and frame which actuates the rotary motion. After the full details therein explained, I hope I may conclude that this particular part is so far finished and ready to put in its place.

It is important that the screw, and consequently the frame, stand perfectly square or tangential to the wheel. I have on more than one occasion rejected work of this kind, although very little out; but still it was not correct. The argument put forth in favour of its passing being that it would work just as well—as far as causing a rotary motion, yes; but, for our present purpose, certainly not. It must be remembered that an extended winch-handle has to be employed when this motion is in use, also a gun-metal arm supporting the end of a long spindle

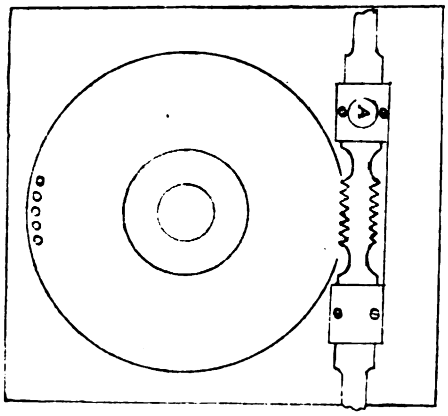


Fig. 1.

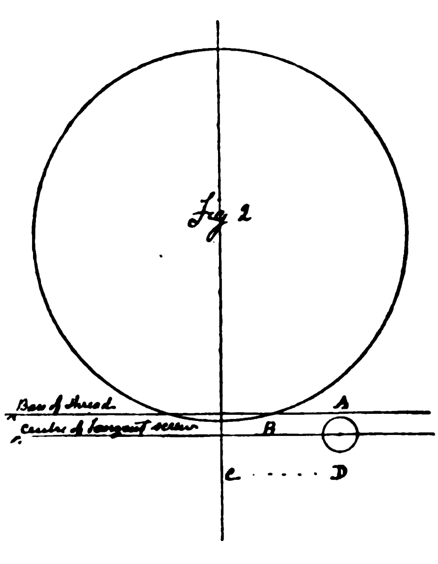
carrying a mitre-wheel, when fitted to work in connection with the spiral apparatus; therefore it will be obvious that a small error in the pitching of the frame would become so multiplied that we should find ourselves in difficulties, which might cause much trouble to overcome.

Having made this as impressive as I can, I will endeavour to point out as clearly as possible the best way to set out the work to overcome the difficulties.

In the first place, it is essential that the exact point at which to drill the hole in the plate that is to receive the stem of the tangent frame should be determined, I have set out, in Fig. 1, as clearly as possible, the best and safest way to set about this particular part. The illustration shows the frame and screw in its place; if we regard this as what we may call a surface or top view, A represents the stem of the frame, which is, of course, at the base; but the circle shown together with the



other points clearly define the manner of obtaining the correct position in which to drive the plate.

Now, if we strike a line tangential to the wheel at the precise depth of the bottom of the thread (A, Fig. 2), and another line in the same plane to correspond with the centre of the tangent screw B, it will be seen that the position of the hole to receive the stem of the frame is certified in this direction, providing, of course, that the stem is immediately under the centre of the bearing through which the screw passes. This must be fully ascertained, and if any error exists in this respect, allowance must be carefully made for it when setting out the work. So far we have the means provided of pitching the line in the one direction, and to obtain the distance from the centre of the wheel it is simply to take half the length of the frame C D, so that the centre of the screw will work in the wheel when in its place. I have thought it better to give a second illustration of this, as it may materially assist in the ultimate result.

And now I am going to explain what may be regarded as another little piece of dodging, but this is not exactly so; but I wish to point out and make it clear that in order to facilitate matters with respect to any very slight errors in pitching the centre for the stem, if there should be—and it is not at all impossible, although after the above details it should be most improbable—let us err on the right side. By this I would suggest that the operator should be quite certain to keep the centre of the line (B, Fig. 2) absolutely perfect if possible, and it is, of course, to be done; but here I will show that if the hole should draw, as it is termed, outwards, the screw, when in its place, would fall to an angle inclining inwards, for which there is absolutely no remedy. But if there should be a very slight deviation tending in the reverse direction, the angle of the frame would assume the opposite, and in this case, the error being very slight, we may get out of it. The wear of a series of revolutions of the screw in the wheel may be sufficient to allow the screw to become tangential. If so, that is all we want. If this should not be quite sufficient, a few rounds of the router in the wheel may assist without the least detriment to the latter.

All this, I need scarcely say, must be prevented by the exercise of care as to the points explained; but as there is no infallibility attached to any individual mechanic, amateur or otherwise, I like to give all the little hints that may be useful, should occasion arise, when they may be of assistance.

I think we may now pass on to the third slide, which is made as shown in Fig. 3, the dimensions also given. This slide, it will be seen, is made of considerable less width than those preceding it; for this there is every reason, which will soon become clear.

When this slide is planed, and the surfaces got up, it may be fixed to its place before the metal slide which works upon and carries the fourth, or tool-box slide, is fitted. As will be seen by the illustration, Fig. 3, the slide is made about 7¼in. long by 2¼in. wide, leaving an interval at the centre of ⅞in. for the passage of the nut. With regard to the length, I give it as 7¼in. about, for the simple reason that a ¼in. one way or the other is of no moment, and as I shall show a new method of attaching the nut in two different places, it is well not to increase the length of this slide.

We will now set about the fixing of the slide to the top surface of the worm-wheel. In order that this may be perfectly clear, I have shown in Fig. 4 the manner in which the four screws that hold the slide to the wheel are placed. It will be noticed that the two screws, 1 and 2, come within the circular bearing. This is a matter of no importance, and is no detriment. On the other hand, it is an improvement to get the screws as far apart as possible. The two screws at the opposite end, it will be seen, come partly on the bearing only.

The holes in the wheel must be thus carefully set out, drilled and countersunk with a sharp keen cutting-tool. The cutting out of the holes without raising a burr is of great importance, as the removal of anything of the kind is likely to cause damage to the finished surface of the wheel. It will, of course, have to be gone over; but the less required to be done the better. Having the four holes finished, the slide must be arranged on the surface to which it is to be fixed, as shown by the dotted lines. It will be, of course, clearly recognised that, as seen, the wheel is placed on the slide as it is to be fixed, the object being, as before stated, to show both the position of the slide and the screws that hold it. The slide must be set very accurately across the centre of the wheel. Here I must impress upon my readers is another point requiring special care and attention, as any want of truth in this setting will probably cause trouble ultimately. This slide is at times used to pass the cut forward, and it will be quite clear that should the slide be out of the direct line, the penetration would be at a slight angle, and thus render many works substantially inaccurate.

The best way to insure this point is to set out the slide as indicated in Fig. 4, then mark off from the hole in the wheel a distinct circle on the

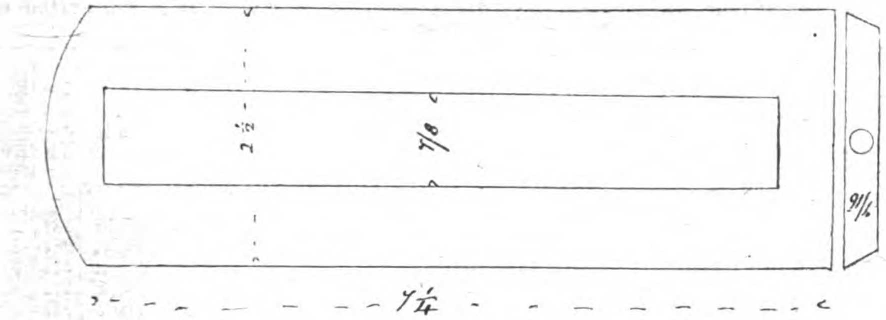


FIG. 3.

slide, and drill very carefully the latter to receive the tap which is to make the thread. As to the size, ¼in. is a very good size; but should any other tap be ready to hand a shade different either way, it will answer just as well. With one screw in its place we have the means of holding the slide securely to the wheel while the three succeeding holes are marked off.

The screw with extended head which holds the wheel to the plate of the second slide must be made to move freely under the slide when fixed. This is simply a matter of slightly reducing the thickness until it is below the surface of the wheel, and when finally putting together, this screw must, of course, be in its place before the slide is fixed to the wheel. It may seem superfluous to mention this; but as I have heard such a deal of indifferent language emanate from this simple point being forgotten, I think reference to it will not be out of place.

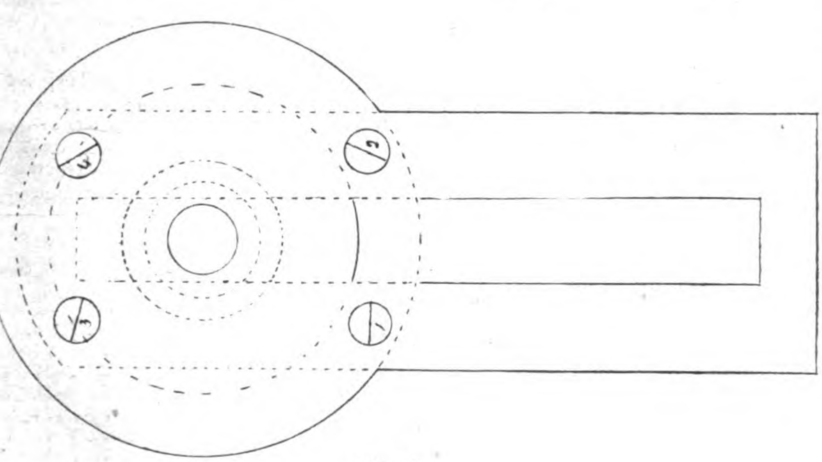

FIG. 4.

Reference to Figs. 3 and 4 will show that one end of the slide is reduced to a curve, and this to correspond with the diameter of the wheel. The object of this is also, its being placed away from the extreme edge of the wheel; Fig. 4, dotted line, is to allow sufficient space for a circle of holes to operate in conjunction with a stop, or stops, which will be fully explained. If for any reason it is preferred to square the end, there is no objection, provided it is fixed in a similar position, in order that there be sufficient room for the stops to be placed in the holes thus provided.

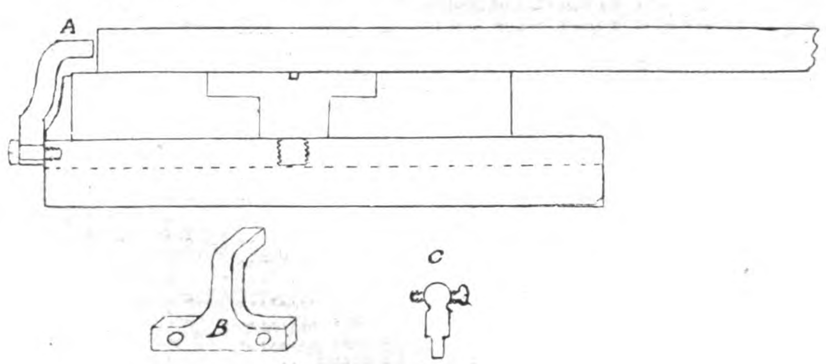

FIG. 5.

In Fig. 5 I have provided a section that will both clearly show the meaning of my previous remarks, and fully illustrate the wheel in its place with the top slide fixed; also the stop, which is in reality a segment stop. If we take observation of A, Fig. 5, it will distinctly show the manner in which the stop is made, also that in which it is fixed to the plate of the second slide, which carries the wheel. It is made from a small steel forging, and filed up to the shape shown in B, Fig. 5, which clearly defines it in all ways. There it will be seen that the two holes through which the screws pass are drilled through exactly in the centre of the base, and this must be rather less than the thickness of the plate to which it is screwed, so that it does not interfere with the traverse of the slide.

As the pins which fit into the holes in the wheel are necessarily at the top, the stop must be carried up, as seen, to about the centre of the third slide, and it must be left as rigid as possible, because when the wheel is moved round under the influence of the screw it may happen that undue force may be applied, which would tend to either force it out of its place, or create a pressure upon the pin that might distort the hole. It will not be found that there is any excess of space, and all these small but important parts must be very carefully worked up and fixed as detailed.

This stop should also be fitted to either side of the plate, in order that it may be removed from one to the other, which is a matter of no difficulty, and, as it is only to repeat the process, no more need to be said on this point, except that it is a most necessary adjustment, and must not be forgotten. It often happens that the distance or space required cannot for various reasons be attained from the one position, but may be easily effected by the simple movement of the stop, as I have explained.

We now come to the pins, which have a distinct character, and this is illustrated by C, Fig. 5. It will here be seen that it is provided with a short and slightly taper pin at the base, which fits into the hole in wheel. Here again is a matter for much care. It will be at once obvious that if this pin does not accurately fit the hole, the pressure cannot be equally maintained throughout a long series of cuts; the body is carried up, and on the top it is turned to a ball, which has passing through it an adjusting screw. This is for the purpose of regulating more closely the relative distances that may at times be required between the spaces set out. For instance, it may be that a short distance representing but a small portion of what would be acquired by moving the pin one hole forward. In this case the adjusting screw is moved, and so the exact segment required is readily obtained.

When the holes in the wheel are drilled, it is better in the first place to use a sharp double-angle drill, and as I have pointed out what is likely to occur by over-pressure, a carefully made taper bit should be ready to take the place of the drill, and passed into each hole exactly the same distance, certified by a stop to the slide which carries the drill frame.

The position and approximate size of holes will be seen in Fig. 1. There should be 60: that number is found to be sufficient for all practical purpose. If there is any particular fancy to have more, it does not matter, provided it does not bring the holes dangerously close. However, the space roughly shown between each in Fig. 1 will be a guide to anyone who has determined to overcome the task. I have taken the opportunity of giving illustrations of all the different parts, as I consider them of much greater service than the matter, considering that each one is also fully explained, and I think that when carefully studied, little difficulty will be found in fully understanding the many points referred to. There is ample room for a good display of workmanship to get to the above stage, and in my next we shall proceed to the fourth and final slide, composing the spherical slide-rest.

ASTRONOMICAL NOTES FOR DECEMBER, 1899.

The method of finding the Sidereal Time at Local Mean Noon at any other station is described on p. 454 of our LXVIIIth volume.

As the Sun is passing through a period of Minimum of Spots, his blank disc ordinarily presents nothing to interest the observer in any shape or way, though on rare occasions small spots may be discerned on his face.

At 1h. a.m. on December 22 the Sun is said, technically, to enter Capricornus, and winter is supposed to commence. By this is meant the "sign," and not the constellation Capricornus, as at the instant specified he will be a little to the east of the 4·6th magnitude star 4 Sagittarii. This is the theoretical date of the shortest day; but in London no difference in this respect will be perceptible from the 17th to the 25th inclusive, during which period the Sun will only be 7 hours and 46 minutes above the horizon, and, of course, 16h. 14m. below it. Should the sky be clear, from the 19th to the 24th will be an excellent time for determining the meridian by the ancient method of equal altitudes, as the Sun

scarcely sensibly changes his declination during the few hours that he is visible, and, being low down, must obviously cast long shadows. On the 21st and 22nd this method may be applied so as to obtain a very fairly accurate result indeed.

There will be

An Annular Eclipse of the Sun

on December 2; but as it will be only fairly visible in the immediate neighbourhood of the South Pole, no further reference is needed to it here.

† Near approaches. A description of the above table will be found on p. 455 of Vol. LXVIII.

The First Contact with the shadow occurs at 66° from the north point of the moon's limb reckoned towards the east. The Last Contact 59° towards the west—in each case as seen with the naked eye.

Mercury

comes into Inferior Conjunction with the Sun at 5h. a.m. on the 6th, and is, of course, there after a Morning Star. He is, however, very indifferently placed for the observer, for although he rises more than an hour and a half before the Sun towards the end of the month, yet he has very considerable South Declination, and is still immersed in the mists of the winter horizon by the time it is daylight. His angular diameter increases from 9·4″ on the 1st of December to 9·8″ about the time of his conjunction, but diminishes to 5·8″ by the end of the year. He attains his Greatest Elongation west of the Sun (22° 5′) at 1h. p.m. on the 25th.

31	17 9·5	21 44·0	10 31·0 ,,

The curiously-looped path indicated in the above ephemeris lies mainly in Ophiuchus, though in describing a small portion of it, Mercury just enters into the confines of Scorpio. The region in which it is described is a blank one.

Venus

is an Evening Star from the beginning to the end of December; but, as in the case of Mercury, her very great South Declination is terribly against observing her. The gibbosity of her little disc is now quite perceptible in the telescope; but she is far from being an interesting object. Her angular diameter increases quite insensibly from 10·6″ on the 1st to 11·4″ by the 31st.

The path indicated above crosses practically the entire width of Sagittarius and a considerable portion of Capricornus. On the evening of the 6th She will be less than 1° north of 3·1 mag. star λ Sagittarii; but this is the only star of any size that she will approach.

As far as the planets are concerned, the night sky is still a blank,

Jupiter

only rising some three hours before the Sun, even on the last day of the year, and

Mars, Saturn, and Uranus

being too close to him to be visible; but

Neptune

comes into Opposition to the Sun at 5 p.m. on the 17th, and, with his considerable North Declination, is now visible during nearly the whole of the ordinary observer's working night.

* Early morning of the 2nd.

The method of finding the Greenwich Mean Time of Southing of either of the stars in the

above list on any other night in December; as also that of determining the Local Instant of its Transit at any other station, is described on p. 456 of our LXVIIIth volume.

It must be noted, however, that the rules there given are not rigidly accurate as applied to Polaris, or, in fact, to any close circumpolar star, although they will doubtless be found sufficiently so in practice for the regulation of any ordinary clock or watch whatever.

And on other occasions when daylight will render the phenomenon invisible.

Shooting Stars

are not particularly numerous or plentiful in December. The principal shower may be looked for on the night of the 10th. It is that of the so-called Geminids, from the situation of its radiant point somewhat to the west of Castor; but, unfortunately, the moon will not set until midnight on the night in question. Smaller displays are predicted for the 4th, 6th, 8th, 12th, 22nd, and 25th.

MILLWRIGHT'S WORK.—XVIII.

METHODS of calculations based on trigonometry are given in textbooks for obtaining the lengths of belting. In the shops the length is always taken with a cord laid round

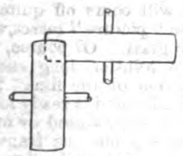

FIG. 112.

over the pulleys—a safe and simple way. After the length is obtained thus, a slight allowance is made for tightening. That is done, because, if the belt were laced up to the exact length given by the cord, it would fit too easily on the pulleys, and would have to be relaxed almost immediately.

The allowance given varies with the character of the belt. The allowance should be greater in a new than in an old one, in which most of the stretch has been taken out. Generally, before new leather belts are used they are stretched a little by hanging them from a beam and loading them with half-hundred weights, or by using a belt-stretcher.

The allowance given when lacing depends on the length of drive. From ½in. to 1in. in 10ft. less than the measured length is a fair allowance, depending on the conditions just named. In any case the tension will soon fall by reason of some stretch taking place.

To measure the length of belting when in the roll:—To the outer diameter of the coil in inches, add the inner diameter, also in inches; multiply this sum by the number of coils in the roll, and by 0·1309. The product will give the length of the belt in feet.

To settle a minimum distance between pulleys is not always easy, because circumstances often do that. Reddaway and Co. fix it at one and a-quarter times the sum of the diameters of the driving and the driven pulleys. If pulleys are nearly equal in diameter, they can be brought closer; if much disparity in size exists they should be set rather farther apart; but an excessively long drive causes the belts to sag, and flap, by their great weight.

When possible, pulleys are best proportioned to give belt speeds not exceeding the maximum limits of from 3,000ft. to 4,000ft. a minute. Reddaway's rule is:—For 3,500ft. per minute, the number 13,400ft. divided by the number of revolutions per minute gives the diameter of the pulley in inches. The same number divided by the diameter of the pulley in inches gives the number of revolutions per minute, at 3,500ft. belt speed.

Horse-power of belting as given in tables is

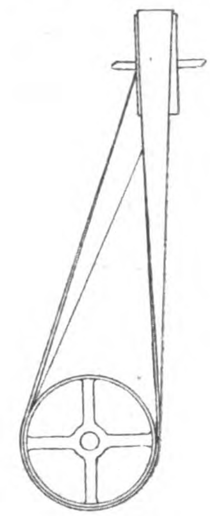

FIG. 113.

very uncertain, because so much depends upon conditions. Tensile strength, speed, grip on the pulleys, which is dependent on width and arc of contact; freedom from slip or otherwise, all affect results, so that to assume that a given belt will

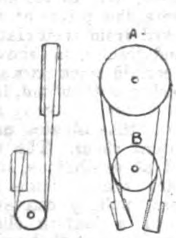

FIG. 114.

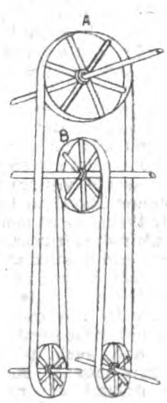

FIG. 115.

transmit an exact quantity of horse-power under all conditions, is to expect too much. Allowances have to be made, and judgment exercised.

A useful and safe rule is to allow 50lb. working strain for every inch of breadth in a single belt, and 80lb. in a double one.

The driving of pulleys at various angles with

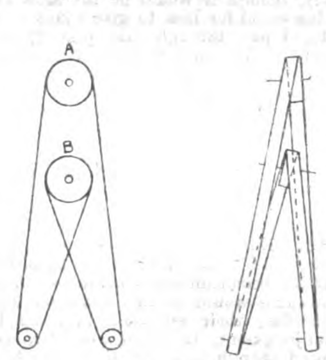

FIG. 116.

twisted belts is one of the curious feats of engineering. One would think such belts must run off. So they do in most instances, if the direction of revolution is reversed. But if the simple rule is remembered, that the edges of the driving and the driven pulley are kept in the same plane, Fig. 112, then the others can come as they will. A few examples of such drives are given in succeeding figures, for some of which I am indebted to Messrs. Tullis and Son.

Fig. 113 is the most common drive met with, being constantly used for transmitting motion between pulleys at right angles. Fig. 114 shows a belt transmission between pulleys, A, B, which are not in the same plane, the belt being brought round guide pulleys. Fig. 115 is a case of two pulleys, A and B, at right angles, and very close together, being driven through guide pulleys. In Fig. 116, two pulleys A and B are situated too closely for a good direct drive to be obtained. Hence the belt is brought round the guide pulleys

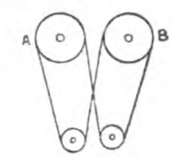

FIG. 117.

seen below. The shafts of A and B may or may not be parallel. Fig. 117 is an instance of pulleys A and B in such proximity that a crossed belt could not be used with effect. The belt is, therefore, brought round indirectly through the guide pulleys beneath.

Fig. 118 shows how shafts at right angles can be driven by belting carried round guide pulleys, through which the strains on the belt can be equalised. Fig. 119 shows another similar case with different arrangement. Fig. 120 illustrates a quarter-twist drive, in which the twist of the belt is removed by a guide pulley before it is delivered to the driven pulley. In Fig. 121 a belt is seen transmitting power between two shafts which are parallel, but not in the same plane, guide pulleys intervening. In Fig. 122 a quarter-twist drive is seen between shafts which are not parallel, a case in which no guide pulley is required if a thick-sided link belt is used.

Instances of this character can be multiplied abundantly. If a given drive is necessary, pulley arrangements can be designed to suit. The awkwardness and the undesirability of such drives is quite another matter. They are generally absorbent of power, and injurious to the life of belting. When they are unavoidable then the thick-sided link belting, described in the last article, has advantages. And so have ropes.

Of the numerous kinds of belting made of canvas, cotton, hair, and cementing materials their principal advantages lie in drives in the open air, in hot rooms, and places where they are exposed to steam and water. The frequent objection to

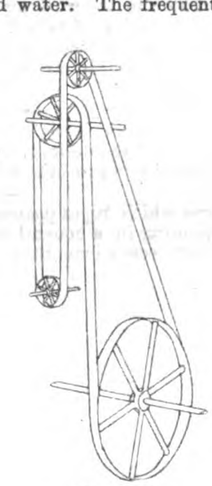

FIG. 118.

them is that the edges fray out. But this is got over in some instances by the use of protective edgings. The Reddaway, the Gandy, the Dick's, and other beltings are well and favourably known, and are used extensively. Another point in favour of these, besides their ability to stand heat and moisture without alteration in length, and without being spoiled, is, that they stretch less than leather, that they are stronger, and that they slip and creep less.

Reddaway and Co., of Manchester, have put down a large number of heavy drives in mills with their camel-hair belting. The compound system of driving, illustrated in the last article, is carried out also by this firm. In an ironworks at Warrington, a compound drive of three belts,

each 16in. wide, is used to operate three sets of ingot rolls from one driving-wheel. Large numbers of the Lancashire cotton-mills use these belts. Thinner camel belts will perform the same work as those of leather—a $\frac{3}{16}$in. belt driving as well as a $\frac{1}{2}$in. one of leather, with the numerous advantages in regard to diminution of stress and ease of movement that follow. But here we must

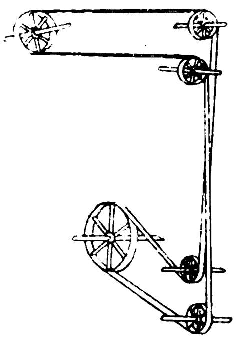

Fig. 119.

leave the belting for a section of modern millwright's work, equally interesting—namely, ropes.

(2) *Ropes*.—Mention was made in Article XV., p. 266, that the users of leather belts might take lessons from the designers of rope drives, in respect of working stresses. The latter is by no means so novel as many might think. It was introduced over forty years ago in the shops of Combe, Barbour, and Co., of Belfast, shops which the writer was privileged to visit a few years ago, and in which the machines are mostly driven by ropes instead of belts.

Rope driving owes nothing to theory, either in

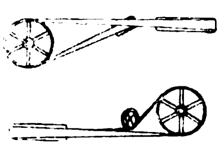

Fig. 120.

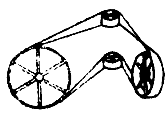

Fig. 121.

inception or development. A mere incident, the use of a rope on an expandieg pulley, led to its invention. The breaking strength of a rope bears but a slight relation to the working strain permissible. The velocities of travel have been made the subject of experiments, and the maximum and the best speeds are thus settled. Curiously, Mr. Combe settled the best angle of sheave, 45°, at the beginning by experiment, and that is still adhered to closely to-day. Experiment, too, has settled the desirability of certain changes in angle of sheaves to suit different conditions of driving.

The advantages which ropes possess over belting are not, speaking in a general way, great; but under certain conditions they are better.

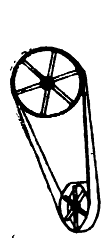

Fig. 122.

They are much better for twisted drives. We have seen how awkwardly half-crossed belting drives, and how the bevelled belting has been designed to obviate this difficulty. Ropes fulfil this function more efficiently. Again, in very wide main-driving belts, the trouble is great, due to insufficient contact with the pulleys. Using ropes, the contact of every rope can be insured. Another point is, that the tightening up of a wide belt involves much loss of time, while a single rope can be removed, and respliced, while those remaining will continue to drive.

Having thus cleared the way, the principal practical points relating to rope driving may be considered immediately. J. H.

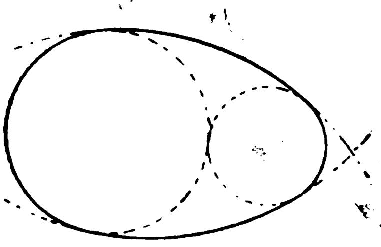

Fig III

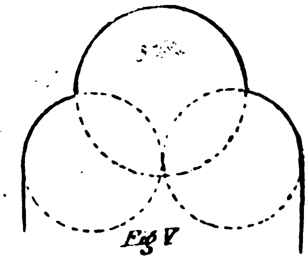

Fig V

A SUGGESTION TO LANTERN-SLIDE MAKERS.

In these days of ceaseless improvement and progress it is not a little surprising to find that the appearance of a lantern slide, as shown on the screen, has made no advance whatever. The screen itself has been improved to a degree which probably touches the possible limit. Lanterns, lenses, and illuminants we have in endless variety and with endless virtues; the attainment of the ideal in this direction appears to be subject only to the means of the buyer. The views produced by capable workers, within their limits, leave nothing to be desired. But how are they set forth? With the same ugly plainness that would evoke a storm of condemnation were it applied, say, to pictures. What would visitors say were the prints at the Salon and Royal to be removed from their elaborately thought-out mounts and frames, and shoved into plain deal frames, all of certain stock sizes and shapes, and retailed at so much per thousand, like bundles of firewood? And yet this is exactly the method, varied only in detail, that obtains universally in the case of lantern slides. The rebuke not infrequently heard at exhibitions, that such and such pictures are simply "made" by their mounts and frames, nobody can ever have dreamt of applying to a lantern slide. Yet a little thought must convince one that many slides are seriously hampered by their lack of a suitable setting. A picture without a frame is like a beautiful woman dirty, unkempt, ill-clothed; or like a hot grog without whisky—choose your metaphor to match your ethics.

The reason that will at once be urged in justification of the present state of affairs, is that slides are turned out in far larger numbers than mounted and framed prints. No man would dream of exhibiting at one show from 60 to 120 pictures (the gods preserve us!), though it would be the most natural thing in the world for him to give a lantern entertainment and pass through that quantity of slides in a single night; and if the same amount of thought and labour had to be bestowed on the making of each of these slides as in the case of pictures prepared for exhibition, then lantern shows and lantern slides would be much rarer than they are.

Inshallah! Would it were so! But there is no question of putting an ornamental border on all one's slides. By far the larger number do not require it, and, indeed, would only look ridiculous if so treated. Nobody in his senses ever puts an elaborate frame round a chart or an oleograph. The point has been sufficiently laboured. Admitted that some slides would be the better for an ornamental border, their selection may be left to individual judgment. In our own case two methods are followed, though, no doubt, there may be others as good which have not occurred to us.

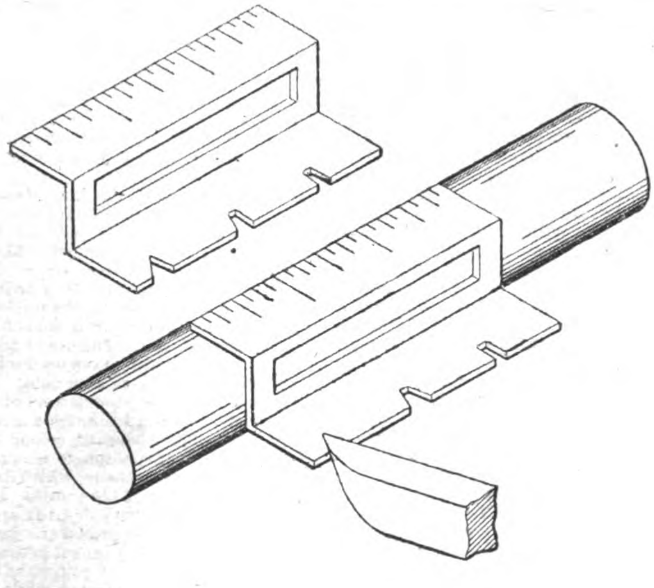
One way is to make little mats of translucent paper, such as the so-called "butter-paper" used by grocers, and sandwich these between the positive and the cover-glass. A second way is to frost or varnish the cover-glass itself, taking the necessary precautions for keeping clear the central portion. Before entering into the details of these methods a word must be said regarding the preparation of the positives themselves.

It seems to be the universal custom when making slides (especially by contact) to let the image cover the whole surface of the plate, and then, by a process analogous to the trimming of prints, to cover up the marginal parts of the view not required with an opaque mask. Such a proceeding must be avoided in making slides that are to have an ornamental border. The opaque mask should be placed in position before the plate is exposed, and precautions should be taken in developing, &c., to keep the margin quite free from fog and stain. Slight veiling can subsequently be removed with a suitable reducer, applied with a brush. If, however, it is desired to put an ornamental border on a positive which has already been covered to the edges, we have found it practicable to carefully cut the film all round the portion which is to be retained, immerse the slide in one of the baths usually recommended for stripping a film, and then roll back and peel off the marginal "trimming" of the latter. It will come off quite neatly at the cut, and leave the "picture" intact, surrounded by a margin of clear glass. Of course, the slide must not be left in the solution long enough to induce spontaneous flotation of the film. The positive is now washed and dried and is ready for use, as if the clear margin had been produced by masking.

Now, as to cutting out the translucent masks. The cutting instrument must be sharp and pointed. The common ink-eraser (Fig. 1) is very useful, though our favourite cutter is an old broken penknife blade (Fig. 2). The easiest mats to make are those of rectangular shape. The straight lines are cut by means of a straight-edge, and the rounded corners are produced by placing in the angles some circular object to act as a guide. When it becomes a question, however, of cutting a circular, oval, or elliptical aperture, some more elaborate device must be used. A raid on the kitchen and neighbourhood will yield ample booty in the shape of circular lids of all dimensions from the tins in which various domestic preparations are stored. With a good assortment of these to act as cutting guides it is fairly easy to cut almost any kind of curved outline by using guides of varying diameters in combination. Reference to Figs. 3, 4, and 5 will explain matters far better than it could be done in words. Having secured the mat, it may at once be bound up with the positive, and will in this state give a very effective grey border, like the pleasant margins we see in half-tone reproductions of photographs. Or it may be further worked upon in a dozen different ways. It may be tinted; a granular pattern may be imparted with a stump, to imitate wood; with a brush and some water-colour, lines and stripes may be marked; and, finally, one skilled in the use of his pencil may produce some elementary form of decorative design. This, however, requires considerable expertness, as, owing to the magnification, the slightest blemish will be much exaggerated. The simplest effects are nearly alway the best.

Our second method is to paste in the centre of the cover-glass a piece of paper a shade smaller each way than the picture, and then at once to pour on matt varnish. This will have set enough in a few seconds to allow the protective paper to be stripped off; it will come away quite easily, leaving the central part of the glass clear. Any irregularity at the edges of the varnish may be scraped smooth. The varnished margin may be worked upon as before.

Yet a third way, and one capable of producing very beautiful results, consists in covering the glass with some crystalline substance in solution. This, when it has evaporated, leaves the glass covered with crystals. It is now exposed to the fumes of hydrofluoric acid, the centre being again pro-



tected with any substance through which the acid cannot act. The result, if a success, is charming, but the process is difficult and uncertain, at least so it has proved in our hands during a by no means exhaustive trial. The experiment is, however, worth making.—Creel, in *Photographic News.*

NEW METHOD OF ARTIFICIAL LIGHTING FOR PORTRAITURE.

At a recent meeting of the Croydon Camera Club, Mr. W. H. Smith gave a demonstration of "A New Method of Artificial Lighting for Portraiture," and in the course of his remarks alluded to a few of the methods of artificial lighting in use for photographic work. There were great disadvantages in the systems already adopted. The arc lamp had its drawbacks in its expense of current and skilled labour required to use it and also in its varying candle power. A certain system of incandescent lights seemed to have an insufficient reflecting surface, and was deficient in actinic rays. Incandescent gas was probably the worst of the lot, as it was found not very durable, the heat was unbearable, and the light far from satisfactory. Flash lamps were rather dangerous, and a nuisance also arose from the fumes and products of combustion. One of the great difficulties experienced with artificial light was the want of diffusion, and he had come to the conclusion that they might obtain what they wanted—viz., a pure reflected light—with magnesium burned in oxygen. With this end in view, he had fitted up a room lined with white paper to diffuse the light satisfactorily and evenly. Mr. Smith then proceeded to explain in detail the various experiments which had led to the present invention. This was a piece of magnesium ribbon, fired by a current of electricity in a glass combustion vessel containing oxygen, with the help of mechanism specially contrived for the purpose. The cost of this system of lighting was very small, the total outlay being about one farthing per exposure. He had arranged his apparatus so that just as much oxygen would be taken up as was needed for the exposure. About 5in. of magnesium wire was used at one time, and the combustion vessel contained a little water to keep it clean.

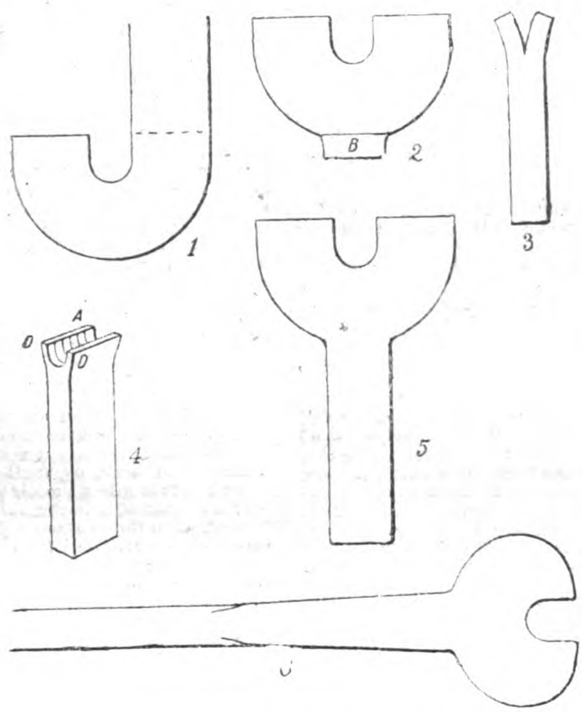
With the assistance of Mr. A. Beales at the camera a number of negatives were taken by the new light of those present, and these, on being developed, showed most clearly the success and importance of the apparatus invented by Mr. Smith.

A KEY-SEAT AND THREAD-TOOL GAUGE.

The cut shows a little tool, recently patented, which should interest the machinist of the shop, and should be found useful for many purposes. It consists, as will be seen, of a double-angle iron, the central web of which common to both angles, is slotted, one of the outer webs being graduated in convenient divisions while the other edge is notched as a gauge for V and other tools. More notches may be inserted than here shown. The slot or slit in the central web, it will be noticed, is nearer one web than the other. The edges of this slit are used for scribing parallel lines upon shafts or other cylindrical figures. When the shaft is small, as shown in the right-hand figure, the inner edge of the slit is used to scribe by, and by using both angles and both edges of the slot, four different distances from the apex of the angle are available. The tool is supposed to be correctly made, and, the ends being perfectly square, when the tool is stood upon end it may be used as a square in places where the common try-square cannot be applied. Other uses of the tool will readily suggest themselves. The inventor is John Beach, Springfield, Ohio.—*American Machinist.*

MAKING A WRENCH.

The following description of a method of making a wrench for nuts on bolts is given by Mr. Arthur Shay, of Orvisburg, Miss., in the *Blacksmith and Wheelwright.* As to how to make a



wrench for a 1¾in. hexagon nut, to be 1½in. in thickness, I submit the accompanying sketches and description:—Bend a piece of 1½in. by 3¼in. iron, and cut off at dotted line, as shown in Fig. 1. Swage down for 2½in., as at B, Fig. 2. Take a piece of iron 1½in. by 2½in. 8in. or 10in. long, and split open for about 1½in. (Fig. 3.) Fuller for the weld and scarf off the points D D. Jump weld A on to B (Fig. 2), and you have an unfinished wrench, as in Fig. 5, with a 1½in. by 2½in. handle 8in. or 10in. long. I would suggest cutting off to, say, 3in. Draw out and weld on handle either of round or flat iron, as may be desired—see Fig. 6, which will give the necessary particulars to the blacksmith, and the directions will do for any size of wrench or spanner.

Rich auriferous deposits are reported to have been discovered in Siberia, on the north-western shore of the sea of Okhotsk.

HEAT LOSSES FROM IMPERFECT BOILER AND CYLINDER COVERING.

The Imprisonment of the Thermal Unit was the name of a lecture delivered by Capt. Wallace W. Johnson before the Railway Engineering Class, Sibley College, Cornell University. The lecturer took the stand that while engineering science has laboured industriously and successfully to convert a potential power of fuel into heat with the least possible degree of loss, little effort has been made to imprison the heat generated till the time when it could be transformed into work. If anything is acting to restrain the free conversion of fuel into heat, the fact soon becomes known through even the crude evidence that the boiler is not making steam freely enough, and a remedy will be sought for. But when steam once generated is permitted to escape as through a sieve, very little attempt is made to hold it back, unless the escape is of a visible character. If the owners or men in charge of a steam plant could see 10 per cent. of the boiler steam and 40 per cent. of the cylinder steam passing through the inclosing walls without doing any useful work, there would be tumult and shouting, and effort directed to find an immediate remedy. These manifestations of zeal to restrain waste of heat are not much in evidence in ordinary boiler and engine rooms, for the reason that the heat is stealing away like a thief in the night, and those responsible for its imprisonment fail to understand that anything is escaping. What is true of engine and boiler rooms in regard to the escape of heat is particularly conspicuous where locomotives and their boilers are concerned. In their case the losses are particularly great, because the conditions of operating expose the locomotive boiler and steam-transmitting parts to more exacting atmospheric conditions than those found in other engines.

It will be an interesting and profitable mental exercise to follow the heat losses partly preventable that happen with a locomotive from the time the coal is passed into the fire-box until the exhaust steam passes into the atmosphere. We have said so much lately about good and bad methods of firing, that we need pay no attention to the man whose hand reaches from the scoop to the treasury of the railroad company. He is working on stronger lines of progression than any other person who has influence in saving or wasting heat. There is very little complaint made against the officials, who are responsible for the escape of heat units after the fireman has done his best to make the most out of every pound of fuel put into the fire-box. This is not because this loss is not often greater than that due to the worst kind of firing, but because the waste does not readily appeal to the senses.

If you stand upon a station platform any day, summer or winter, and a locomotive passes at a lower speed than twelve miles an hour you will feel the warmth thrown off from the boiler and cylinders. Reflection will tell you that the engine moves along giving forth at all times a volume of heat into the surrounding atmosphere. Some engines are more liberal in heating the air than others; but nearly all of them send forth heat rays that can be distinctly felt 6ft. away. The principal source of this radiation of heat is the boiler, and the resulting

loss is due to defective insulation. It is perfectly practicable to make and apply a boiler covering which will prevent the escape of any heat except through the proper channels, and that this has not been done is due to the fact that people in charge are not properly impressed with the magnitude of the losses now going on. To feel the hot air raised perceptibly in temperature by a passing locomotive ought to indicate that the losses from this source are serious; but no data are provided to tell what the aggregate amounts to. This ought to be supplied by accurate tests. Very little has been done to measure these losses, and all we have to guide us are rough guesses. Few locomotives steam so freely in winter as they do in summer, and the cause doubtless is that in cold weather a large proportion of the steam generated is wasted by radiation before it has the opportunity to do work in the cylinders. Mr. J. C. Hoadley, a well-known mechanical engineer, made some tests with ordinary boilers years ago to ascertain the heat losses due to uncovered and defectively-covered boilers, and he found the loss as high as 12 per cent. It must be much greater with a locomotive rushing through the air at a high speed and forcing currents of air under the defective lagging. Considerable progress has been made in the last five years in the introduction of good sectional lagging that prevents the heat units from escaping through the parts where it is applied; but too much of the boiler still remains uncovered.

A surprising thing to us is that some enterprising railroad company does not make systematic tests to ascertain an approximation of the heat losses due to defective boiler covering. This could be easily done by taking, say, three engines and stationing them in an exposed position on a very cold, windy day. One might be covered with the best known kind of boiler lagging, the next with pineboard lagging that had been some months in service, the other might have the boiler bare. The difference in the amount of fuel required to keep the steam pressure close to the blowing-off point would give a good approximation of the value of efficient boiler covering.

If there is one part of a locomotive boiler that deserves more attention than other parts in the way of proper insulation it is the fire-box. Yet the fire-box has been more thoroughly neglected than any other part. This has come about merely because the fire-box presented greater difficulties than the barrel to those planning or applying covering. The flat surface in front of the fire-box gives good resistance for the wind to act upon. The chilling effect of the wind is so great during cold weather that the front of the firebox becomes a veritable condenser of the steam generated inside. Several railroad companies have succeeded in applying effective covering to the whole of the fire-box, and there is no reason why others refrain from doing the same thing, except that the extent of the heat losses is not appreciated.

In this connection it would be well to caution railroad companies against using plaster boiler covering. The plastic part consists invariably of plaster of Paris, which is sulphate of lime. Under certain circumstances that sulphate becomes sulphuric acid, which attacks the boiler-plates, and causes dangerous weakening unless promptly detected.

There is doubtless serious loss of heat going on all the time from the cooling effect of badly-covered boilers; but there is good reason for believing that even greater loss results from cylinder condensation. The best steam engineering authorities say that the result of careful tests proves that from 25 to 50 per cent. of the steam generated in the boiler is condensed before it can be utilised to do work inside of the cylinders. A considerable part of this loss is unavoidable where steam jackets are not in use, and is due to the cooling of the cylinders during the period of exhaust, and the need for heating the metal again to the temperature of the incoming steam. To go more into detail: The steam on entering the cylinders goes into what is a partial condenser, and as saturated steam is ready to return to water as soon as the least portion of heat is abstracted, part of the steam becomes vapour, and has lost its capacity for doing work. As expansion proceeds and the pressure decreases, the condensed steam inclines to vaporise, and it draws heat from the walls to aid this process. By the time the exhaust opens, that end of the cylinder has descended into temperature near to that due to the temperature of the boiling-point at atmospheric pressure.

When the cylinders and steam-chests are badly protected, and most of them are, this condensing process is much more active than it is where good insulation is provided. The saving of heat due to well-covered cylinders and their connections is so great, and the expense of imprisoning the thermal unit so trifling, that it is amazing to find the greater part of our locomotives with no lagging on the cylinder heads, bare metal where the steam passages are, and no intelligent or careful attempt to cover cylinders and steam-chests.

In the course of a conversation the writer had lately with Mr. Aspinall, general manager of the Lancashire and Yorkshire Railway, but better known as locomotive superintendent of that railway, we learned several interesting facts about the difference between well-protected and badly-protected cylinders. Mr. Aspinall built a group of outside cylinder engines for switching purposes, all others on the line having the cylinders inside the smoke-box. The inside cylinder engines cause no annoyance by dripping water from the cylinder cocks, but the new ones, with the cylinders outside, were such a nuisance in that respect that the designer thinks seriously of changing them. That is probably one reason why British locomotives, with their well protected inside cylinders, do their work on less fuel than those in other countries where outside cylinders are the rule.—*Locomotive Engineering*, N.Y.

SILVER PHOSPHATE PRINTING PROCESS.

The patentee of a silver phosphate printing process, Dr. Johannes Meyer, of New York, says it is based upon the discovery of the valuable properties of the silver phosphates when combined with organic acids, such as acetic, tartaric, citric, and succinic acids. The silver phosphates have so far not been employed for photographic or other purposes, and the only mention of any application made of them is to be found in Hardwich's "Manual of Photographic Chemistry." He writes: "Other insoluble salts, such as the phosphate and citrate, render the paper more sensitive than when it has been treated with a soluble salt of silver only." The great value of the silver phosphates consists in their property of forming emulsions with suitable organic acids, which behave in all repects like the well-known emulsions of the silver haloid salts with albumen, gelatine, or collodion. Dr. Meyer proceeds: "I have discovered that the silver phosphates, aside from being soluble in ammonia, phosphoric acid, and nitric acid solutions, as was well known, form solutions with a number of organic acids, as, for instance, acetic, tartaric, citric, and succinic acid; but under certain conditions, silver phosphates will form, in conjunction with an organic acid, a true emulsion.

I have studied the behaviour of silver phosphate towards tartaric acid in this direction most carefully, and, as the tartaric acid—silver phosphate emulsion—is chiefly employed, I will now proceed to give directions how to prepare and how to use it.

To an aqueous solution of 1 drachm of silver nitrate a well-diluted solution of sodium phosphate is added. The resulting silver phosphate is well washed, by decantation, and brought to the volume of 1fl.oz. To this silver phosphate held in suspension we add 5 drachms of tartaric acid dissolved in 5 drachms of water, at the same time imparting to the containing vessel a quick rotary motion. In this way is obtained a white, jelly-like mass of a volume of 2oz., containing a quantity of silver phosphate equivalent to the drachm of nitrate we started from. It is essential that all the chemicals, including the water, be chemically pure.

To render this emulsion more fluid, it is either slightly heated, or agitated with a glass rod, or by shaking the bottle. In this state it is used for coating the paper or other surfaces on which it is desired to print.

The proportions given above are the best for practical use. The preparation of the emulsion is, however, easier, for one not experienced in this special line of work, by mixing a fluid ounce of silver phosphate with a smaller quantity of tartaric acid; for instance, 2 drachms of acid in 2 drachms of water, when the emulsion will set more readily. When the emulsion is left in its jelly-like state, crystallisation will set in, after some time, while a portion of the silver is retained in the solution.

Citric acid seems to have the greatest affinity for silver phosphate. Twelve drachms of citric acid mixed with 1fl.oz. of silver phosphate will produce a clear, transparent solution which has remarkable sensitiveness and qualities.

The emulsion, or solution of silver phosphate in organic acid thus obtained is then applied in any suitable manner to the surface to be sensitised. It may be applied by means of a soft, flat camel's-hair brush to paper, after which it is permitted to dry. When this sensitised photographic paper is exposed under a negative to direct or shaded sunlight, a positive picture of great accuracy and agreeable tone is obtained. When the paper is first coated with albumen or gelatine, or any similar substance, a photographic print can be produced in less time than by the silver haloids heretofore employed, and not only sunlight, but also artificial light, can be used for producing a direct print. The photographic print thus obtained can be toned by any of the well-known toning solutions, and finally fixed by means of sodium hyposulphite. The print is then washed until no trace of the hyposulphite is left in the same. In place of paper, any other material, such as wood, celluloid, lithographic stone, silk, cotton, or other textile fabric, and other materials, can be coated with the photographic film, and pictures of great delicacy and beauty, not inferior to prints on paper, be produced thereon.

The advantages of my improved process of producing photographic films are that silver phosphates can be employed without the aid of a viscous substance like albumen or gelatine; that the silver phosphate emulsion, or solution, can be spread over almost any surface, like a paint or dye; and that only a very weak solution of sodium hyposulphite, and a short immersion of the prints, is required to remove the unchanged silver and render the prints permanent.

When the prints are left in the fixing-bath for a longer time than a minute, the sulphuration of the prints will commence, which is induced by the organic acid, and which will be completed to blackness of the picture in a few minutes more. Though sulphur toning is believed to have many objectionable features, the prints made by the process described do not suffer in appearance if the sulphuration is not too long continued. The use of albumen will prevent the prints which have been toned by sulphur from becoming yellow and faded by atmospheric oxidation. These results were obtained by a number of tests, continued through a considerable period of time. The dominant colour of the prints made by the silver phosphate emulsion or solution is a brown or auburn shade, which darkens considerably with the drying of the prints. Toning may therefore be dispensed with in many applications in the arts. When the prints are made on textile fabrics they are generally brown in tone, but this can be changed, in the case of cotton, to black, by passing a hot flat-iron over the same, while prints on silk will not undergo this change. Though the predominating colour of the silver phosphate prints is brown, many of them show various other tones, and it must be assumed that certain negatives act as a media for the transferring of colour qualities and influence the production of the tone to a certain degree under conditions not yet known. When a silver bromide emulsion is added to a silver phosphate emulsion, the sensitiveness of the solution is so increased that even the light of a common petroleum lamp is sufficient to produce a direct print. The sensitiveness of the emulsion is also increased by the addition of a small quantity of citric acid. The solution of silver phosphate in citric acid, when applied to a plain piece of paper and exposed under the negative to direct sunlight, produces a print of very agreeable bluish tone, which will compare favourably with other prints in accuracy, in the high lights and in the depths of the shadows.

Paper coated with albumen and sensitised with a silver phosphate emulsion or solution has great durability, and will not deteriorate under climatic influences. It can be used, therefore, at any time for printing, without impairing the quality of the print. . . . The print is removed from the printing-frame directly to the fixing-bath, to which sodium bicarbonate is added when the original colour of the print is to be preserved. The print remains in the fixing-bath for a short time, and is then freed from any adhering traces of sodium hyposulphite by washing it in hot or cold water for about five minutes.

CARTER'S FEED-WATER APPARATUS FOR BOILERS.

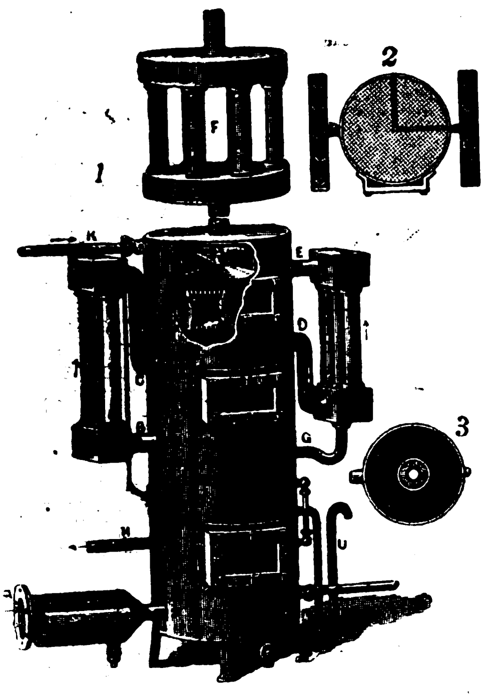
An invention patented by John S. Carter, of 483, Fargo-avenue, Buffalo, N.Y., provides an ingenious feed-water apparatus in which the exhaust steam from the engine is made to heat the feed-water, and is at the same time condensed and returned to the boiler. Means for purifying the feed-water and for separating the oil from the exhaust steam are also provided.

Fig. 1 is a perspective view of the apparatus, with parts broken away to show the interior construction. Figs. 2 and 3 are cross-sections through different parts of the device.

The apparatus is inclosed in a cylindrical casing, in the bottom of which is a chamber provided with a blow-out pipe. The exhaust steam enters this chamber through a drum A fitted with a stationary screw serving to impart a spiral movement to the steam, whereby the oil is centrifugally separated. Leading up from the bottom chamber is a pipe (shown in Fig. 3), perforated near its upper end, and provided with a baffle-plate, causing the steam to pass horizontally into a feed-water heating-chamber. From this chamber the steam passes through a pipe, B, into a condenser comprising two boxes and a number of vertical glass condensing-tubes. From the condenser the steam passes down through the pipe C to a second feed-water heating-chamber, from which it emerges by way of the pipe D. After passing through a second set of condensers the steam enters a third feed-water heating-chamber in the upper end of the casing, by way of the pipe E. The water of condensation from the second condenser is returned to the first feed-water heating-chamber by a trapped or return-pipe G. From the third feed-water heating-chamber the steam passes through a third condenser, F, provided with a vertical outlet-pipe. The steam in passing through the various compartments is condensed, and the water of condensation

runs back into the casing to be employed as feed-water.

The feed-water is led into the apparatus by means of a pipe, K, discharging upon a baffle-plate, from which it passes in a spray to the third feed-water heating-chamber, and is heated by the steam entering the chamber. The several feed-water heating-chambers are separated from one another by means of filtering partitions formed of upper and lower screens, between which filtering material is packed. The water delivered from the baffle-plate passes down through the several screens and filtering



partitions in a spray, is heated by the steam passing through the chambers, and finally reaches a reservoir, from which it is supplied to the boiler, heated and filtered, by the pipe H. The supply of feed-water in the reservoir is automatically regulated by a float-lever, connected by a link with a valve in the pipe K. A water-gauge and a trapped overflow pipe, U, are also provided for the reservoir. The upper filtering-plates or screens, as shown in Fig. 2, are made in two or more sections, to facilitate ready removal when cleaning.—*Scientific American.*

In the United States the smokeless powder stored in magazines, for the use of sea-coast guns, is said to have deteriorated to such an extent as to be dangerous to use. A 10in. gun was lately burst by this powder that had been stored two years, and the resulting examination showed that practically all the stored powder was affected. The cause of deterioration is being investigated.

The Marconi system of wireless telegraphy is to be tested for naval purposes in America, and the cruiser *New York* and battleship *Massachusetts* are being fitted up by Mr. Marconi for the test, with his headquarters on the former. If the experiments are satisfactory a land station will be established, and tests made to determine the value of the apparatus in lighthouses, to warn approaching vessels of danger.

Cheap Opalines.—Old negative-glasses may, with a little care, be used for making pretty opalines. First remove the film by soaking in a 10 per cent. solution of hydrochloric acid, and well wash the glass in warm water, dry, and polish. Make a solution of thin gelatine, and apply while warm over one side of the glass. Then dip the print in water and well squeegee in contact with the glass, and place to dry. When thoroughly dry, bind round the edges with some coloured binding-strips, blue or red, which will greatly improve the picture. It is now complete, unless a strut is required. One can easily be affixed. First paste a sheet of clean backing-paper over the back of the opaline. Then cut a piece of stout cardboard a little smaller than the opaline. Across this a cut should be made so that the card may be bent in the form of a strut. Over the cut a piece of thin linen must be pasted, so as to prevent it breaking in two. Now glue the top part of the card on to the back of the opaline, and allow to set; and then a piece of tape should be pasted on the inside of the loose part of card, and stretched across to the opaline, and pasted there; it will then stand up. Very pretty effects can be obtained at a very small cost by following the above directions.—O. T., in *Photographic News.*

SCIENTIFIC SOCIETIES.

ROYAL MICROSCOPICAL SOCIETY.

At the meeting on Nov. 15, Mr. E. M. Nelson, President, in the chair, Dr. Hebb called attention to the Volume of the *Transactions* of the Jenner Institute of Preventive Medicine, which he thought would be of great interest to those engaged in bacteriological work. Mr. C. L. Curties exhibited a new form of portable microscope by Leitz. It had a folding foot and a removable stage, to enable the instrument to be packed in a small compass. The body was not made to incline, but was furnished with a coarse and fine adjustment, and the stage was fitted with a modified form of Abbe condenser with Iris diaphragm. The President thought the instrument would be useful to those requiring a very portable one; its great compactness was effected in an ingenious manner, while the working parts were well made and finished. The President read a short note descriptive of a set of three simple hand-microscopes, on the Coddington principle, sent for exhibition by Mr. Edward Swan. They were apparently made for a medical man, and could not be very old. Dr. Hebb said Prof. Groves had made some modification in a form of hand-microtome, and had sent it for exhibition. The President called attention to six photomicrographs of the larvæ of gnats, taken from life, by Mr. J. T. Holder. The President exhibited an old Gillett condenser, dated July 20, 1849, which had a collar adjustment. Dr. H. C. Sorby's paper, "On the Preparation of Marine Worms as Microscopical Objects," was read by the President, in the unavoidable absence of the author. The subject was illustrated by beautifully-mounted slides exhibited under microscopes. The attention of the meeting was then directed to a fine exhibition of Foraminifera, by Mr. Earland, shown under a large number of microscopes, with written descriptions explaining the points of interest in each slide.

USEFUL AND SCIENTIFIC NOTES.

Drainage.—In planning drainage schemes provision should be made for removing rainfall per hour as follows:—From roofs—measured horizontally—5in. in depth; from flagged surfaces, 2in. in depth; from paved surfaces, 10in. in depth; from gravelled, ·05in. in depth; from meadows or grass plots, ·02in. in depth.

Lightning conductors are usually made of solid copper tapes in continuous lengths, about ¾in. to 1¼in. wide, and ⅛in to ¼in. thick; or occasionally copper wire rope, ⅜in. to ¾in. diameter. For dwelling-houses and other ordinary buildings a copper rod ½in. diameter, and weighing 189lb. per foot, is frequently used. If an iron rod is used it is generally ¾in. diameter.

We Vary in Weight Hourly.—Mr. W. W. Wagstaffe, B.A., F.R.C.S., advances some curious facts in *Knowledge* for November regarding the—as he calls them—"Ups and Downs in our Daily Weight." He says:—"It is strange to see what absurd fallacies occupy the popular mind. . . . It has been seriously asserted by many people that you are naturally lighter after a meal, and they have even gone the length of explaining this by the amount of gas that is developed from the food. These people must be very uncomfortable after meals! It reminds one rather of the famous fallacy said to have been submitted to the Royal Society, asking why a fish could be put into a basin brimful of water without making it run over. When it was tried at someone's suggestion the water, of course, did run over. Supposing we want to find whether we do really vary in weight or not, there are two ways to set about the inquiry. We can either sit in a weighing-machine and live there—which does not commend itself to most of us—or we can weigh ourselves at regular times during the day, which is more feasible. Here are some figures which represent some actual observations. Average:—

	lb.	oz.		lb.	oz.
9 a.m.—Before breakfast	155	8	(losing	3	6)*
10 a.m.—After ,,	157	4	(gaining	1	12)
12 noon.—Before lunch ..	156	6	(losing	0	14)
1 p.m.—After ,, ..	157	6	(gaining	1	0)
5 p.m.—Before dinner ..	156	12	(losing	0	10)
6½ p.m.—After ,, ..	158	14	(gaining	2	2)

* During night.

By these it will be seen that we lose 3lb. 6oz. between night and morning; that we gain 1lb. 12oz. by breakfast. That we again lose about 14oz. before lunch; that lunch puts on an average of 1lb.; that we again lose during the afternoon an average of 10oz.; but that an ordinary dinner to healthy persons adds 2lb. 2oz. to their weight. What would be the result of a big dinner? It is easier to imagine than describe. And yet on more than one day there was a difference of 2lb. 8oz.; but this is not very excessive, considering that a pint of fluid weighs about 1lb.

SCIENTIFIC NEWS.

The annual eclipse of the sun on Dec. 2 will not be visible from any known land, but it is not improbable that some useful observations may be made from ships sailing over the seas, especially as many captains are now in possession of photographic and spectroscopic apparatus.

A nearly total eclipse of the moon is due on Dec. 16, and will be theoretically visible at Greenwich.

It appears that some observers in this country did see the meteors or shooting stars between midnight of Nov. 14 and the morning of the 16th, but the number of the Leonids seen was insignificant compared to what was expected.

The Russian Astronomical Society has, it is stated, resolved to erect a mountain observatory, but the site has not been finally agreed upon. It appears probable that it will be either in the Crimea or the Caucasus.

The *Bulletin Mensuel* du Magnétisme Terrestre de L'Observatoire Royal de Belgique, by M. L. Niesten, should be useful to those who keep a record of sunspots and of such phenomena of magnetism as the Aurora borealis. It is published by Hayez, at Brussels.

The *Journal* of the British Astronomical Association (Nov. 25) contains the business and official notices, and the usual notes of papers or reports which have appeared in the periodicals which deal with astronomical matters. A brief note announces the death of Mr. Nathaniel E. Green, a past president of the Association, and a Fellow of the Royal Astronomical Society since 1875. Mr. Green was president of the Association in 1896-98, and it is probable that a portrait, with a full obituary notice, will appear in the next number of the *Journal.*

The Parliament of Queensland has voted the sum of £1,000 towards the expenses of the proposed Antarctic Expedition; but it appears that, although so far the proposal has been liberally supported, a much larger fund than is at present available will be required to equip an expedition in a suitable manner.

Mr. Thomas Henry Ismay died last week. He was born at Maryport, Cumberland, in 1837, and came of a race of shipbuilders and shipowners. Apprenticed to Messrs. Imrie and Tomlinson, of Liverpool, he studied shipbuilding from every point of view, and visited many parts of the world. He acquired the White Star line of Australian clippers, and soon afterwards, in conjunction with Mr. William Imrie, formed the Oceanic Steamship Company, and subsequently commenced the Transatlantic service, which has become known to fame as the White Star line, the names of the vessels ending in "ic," as those of the Cunarders end in "ia." The *Oceanic* (the second of that name) is the longest vessel afloat, and made her maiden voyage this year.

The death is announced of Prof. Francis Guthrie, formerly professor of mathematics in the South African College. He was born in 1831, and went out to Cape Colony in 1861. The deceased was an enthusiastic botanist, and, in conjunction with Mr. Harry Bolus, did much valuable work in connection with the "Flora Capensis" in preparation at Kew.

Mr. William Lewis Morgan, M.A., formerly of Oxford, died at sea (on the voyage home from Cape Town) of malarial fever, at the age of 48. He was Lecturer at Exeter College in Biology and at Wadham in Natural Science.

Mr. Dixon Kemp, the well-known author of some standard works on yacht-building, died last week. He was an Associate of the Institute of Naval Architects, and had designed many more or less famous racing yachts, but of late years had interested himself with steam yachts.

To the Paris Academy of Sciences, Mme. S. Curie has presented a memoir on the atomic weight of the metal in radio-active chloride of barium, in which the results of the investigations carried out confirm the original view as to the existence of a new element, which has been named radium.

The Sale of Food and Drugs Act comes into operation on Jan. 1 next, and the Board of Agriculture has issued a number of circulars which concern sellers of cheese, butter, margarine, &c. The board points out, among other matters, that

the provisions of the Margarine Act, 1887, are extended to "margarine-cheese," which expression is defined as meaning "any substance, whether compound or otherwise, which is prepared in imitation of cheese, and which contains fat not derived from milk," and no such substance can be lawfully dealt in, exposed for sale, or sold except under the name of "margarine-cheese," and under the conditions set forth in section 6 of the Margarine Act, 1887. Every occupier of a manufactory of margarine or margarine-cheese, and every wholesale dealer in such substances, is required to keep a register showing the quantity and destination of each consignment of such substances sent out from his manufactory or place of business, and this register is to be open to the inspection of any officer of the board. The Act also enables the Board to appoint officers to execute and enforce the provisions of the Act when local authorities neglect their duty. Another circular addressed to the clerks of local authorities calls attention to the fact that every public milk seller must have his name and address conspicuously inscribed on his vehicle or receptacle for the milk, under a penalty not exceeding £2. Receptacles containing condensed separated or skimmed milk must bear a label clearly visible to the purchaser on which the words, "Machine-skimmed Milk," or "Skimmed Milk," as the case may require, are printed in large and legible type, under a penalty not exceeding £10. A person purchasing any article with the intention of submitting the same to analysis must divide the article into three parts, and must, if required, deliver one of the parts to the seller or his agent. The division of the sample is therefore obligatory, whether the seller requires it or not, and, on the other hand, the delivery of a part to the seller is not obligatory, unless he requires it. It may be doubted whether the penalties are high enough, for the profits when selling margarine for butter are so great that the large dealers can afford to laugh at the "fines."

It is announced that M. Henri Moissan has been appointed to the professorship of inorganic chemistry in the Paris School of Pharmacy, which had become vacant by the retirement of Prof. Riche.

A large number of candidates for the optical diplomas offered by the Spectacle Makers' Company presented themselves for examination at the Northampton Institute, Clerkenwell. Alderman Sir Reginald Hanson, M.P., the Master of the Spectacle Makers' Company, in a short address to the students, declared that owing to the technical instruction imparted under the ægis of the guild, the style and conduct of the optical trade of the country would be improved, while the interests of the public would be further protected, and the British optical trade would be increased and fostered. It was essential that the practical optician should be proficient in the mechanical requirements of his calling and thoroughly competent to distinguish between those cases in which glasses could be supplied by him and those which required the skill of an oculist. Sir Reginald Hanson having strongly deprecated the idea that opticians should take the place of the ophthalmic surgeon, pointed out that the function of the former was to deal with the eye as an optical instrument, and further, that the moment they found the eye was incapable of receiving perfect vision with the aid of the appliances of the trade it was the bounden duty of the optician to seek advice.

It is rather singular to read, after all the warnings that have been given in the scientific papers, the ideas of the uses to which aluminium can be put. In alloys it is a useful metal, but pure it is treacherous. It is not, however, so bad as the following paragraph asserts:—"Aluminium as an industrial metal has been very disappointing. Its undeniable merits, strength and lightness, are discounted to a serious extent by defects which it does not appear possible to overcome, so far as present experience enables us to judge. However brilliantly polished in the first instance, it oxidises very rapidly, and assumes a shabby appearance in ordinary use. It must be remembered that the United States Government made most exhaustive experiments with aluminium and alloyed aluminium for coinage a few years ago, but did not find these experiments at all so encouraging as to entitle them to even a tentative practice." The properties of aluminium have been known for a good many years, notably that it oxidises very rapidly in the presence of sea air, which is always more or less impregnated with salt. Some of the alloys of aluminium appear to be very useful, but pure aluminium has not yet been accepted for anything but special purposes.

It is reported that a fine specimen of the honey buzzard (*Falco apivorus*) has been shot near Boston. As these birds were supposed to be extinct in England, the capture has excited much interest amongst ornithologists. The bird was busily engaged in ransacking a wasps' nest in search of the larvæ, of which it is very fond. There may be some excuse for capturing rare birds, so that the "larger number" may have an opportunity of inspecting them in a museum; but many of them, left alone, would become more numerous in this country, and the honey buzzard is said to be a useful bird.

Another natural history note reads:—"While fishing in Hollesley Bay two fishermen brought up a crab, having fixed to its back a perfect four-year-old oyster. The curiosity is to be sent to Ipswich Museum."

A bottle-nosed whale, 66ft. long, weighing about eight tons, was stranded the other day off the cannon cartridge buildings, Woolwich Arsenal. It came up the river with the tide, and when it found itself stranded on the reed bed "blew" furiously, and turned "somersaults," injuring itself on the stones, and colouring the river with its blood. About two o'clock, the crew of a steam tug fastened a rope to it, dragged it off the beach, and took it in tow, with the intention of consulting the Thames Conservancy as to what was to be done with it.

In the description of a patent taken out (or more properly speaking granted) in the United States to Mary L. Whitfield, of Memphis, Tenn., for electro-medical apparatus, it is stated that it has been impossible to obtain good results, because the current raised was generated by outside means and passed into the body, so that it was conducted by the blood and not by the diseased portions, except those over which it had to pass on entering or leaving the body. By means of the patented apparatus, it is stated that "the entire body or any desired part can be treated by causing induction to take place in the diseased part, so that every particle of the body, when placed within the influence of a changing magnetic field, interrupts lines of force to generate electricity and to form a conductor."

It is announced that the torpedo-boat destroyer *Viper*, which is fitted with steam-turbines on the Parsons' system, attained in her trials on the measured mile a speed of 37 knots. Those most interested are, it appears, not responsible for the statement.

The lead-covered electric wires used at the official residences in Calcutta of the Lieutenant-Governor of Bengal have deteriorated considerably, and a large part will have to be renewed soon, although it is only about three years since they were put in. They were buried in the plaster, it is said.

At the Society of Arts, on Wednesday, Dec. 6, Mr. Joseph Cash is to read a paper on "Artificial Silk."

A THERMOSTAT has been designed in America to give warning of spontaneous combustion in coal pockets. A compound solder-release thermostat, encased and protected by iron pipe, is placed in the centre of every 10ft. cube of coal, both horizontally and vertically. The thermostat has two operating points, one at 155°, the other at 286°, and as these two points are reached bells are rung and warning given of an approaching fire.

What is Fog?—Prof. Barr, of Glasgow University, says it used to be commonly supposed that the particles forming a fog or a cloud consisted of small vesicles or bubbles of water, filled with some very light gas. This extraordinary conception arose from the supposed necessity of finding some explanation of the suspension of these particles in the air. The process of formation of such vesicles, and the presence in them of gas which was lighter than air, though subject to a very considerable pressure on account of the capillary contraction of the envelope, were mysteries never explained. But the principle just given will suffice to indicate that very small particles of water will fall slowly in still air, while a very slight upward current will suffice to keep them from descending at all in the case of very small particles. Aitken has shown that the globules forming a fog or cloud consist each of a film of water condensed upon a particle of dust. The core is therefore solid, not gaseous.

LETTERS TO THE EDITOR.

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks; a vice from whence great inconveniences derive their original."
—*Montaigne's Essays.*

THE LATE MR. N. E. GREEN, F.R.A.S.—THE TIDES—THE LEONIDS (THE LIGHT THAT FAILED)—A SPURIOUS "ASTRONOMER ROYAL."—ALPHA AND BETA ORIONIS—ROTATION OF A SHELL—PRONUNCIATION—THE LIMITS OF HUMAN KNOWLEDGE—"USSHERING" IN THE LEONIDS—STONEHENGE—THE LIGHTNING FLASH—SUNSPOT MINIMUM—DEWCAP FOR REFRACTOR.

[43073.]—BY the death of Mr. N. E. Green, F.R.A.S., the descriptive and observational provinces of astronomy have sustained a severe loss, and are distinctly the poorer. As an astronomical draughtsman he had but few equals indeed, either in this country or any other; his drawings of planetary detail being at once remarkable for their artistic excellence and for their rigid accuracy of detail. His observations and really superb sketches of Mars made in Madeira in 1887 are even yet unsurpassed for beauty and truthfulness, and are now classical. They may be studied with advantage by the young observer, whose ideas of the physical configuration of the surface of our neighbour in space have been derived from some of the recent fancy sketches of Areographical detail which have been published. Mr. Green drew what he saw, and really saw (and did not merely imagine, like some folk) what he drew. The student could have no safer guide than he was in the delineation of celestial objects.

Some few months ago the Rev. J. H. S. Moxly, the Chaplain to Chelsea Hospital, wrote a book, which was published by Rivingtons entitled "The Tides Simply Explained, with Practical Hints to Mariners"; the gist of his theory being expressed in the following sentence: "Well then, if the attractive force raises a tide under the moon, the force opposite the attractive force will produce a similar effect on the opposite side of the world." This "opposite force" being, as we are told a few lines previously, that "which keeps the earth and moon asunder." But Mr. Moxly is not even original in his paradox, for on October 5, 1898, more than a year ago, a paper was read before the North-Western (Manchester) Branch of the British Astronomical Association by Mr. E. McGauran, advocating the identical hypothesis. I cannot but feel that Messrs. McGauran and Moxly might both read Prof. Darwin's admirable book on "The Tides" (and notably Chapter V. of that work) with very great advantage indeed.

I sincerely hope that some, at least, of my brother-readers have been more fortunate than I was in the observation of the late shower of Leonid meteors—always supposing that there was anything worthy to be dignified by the name of a shower at all. Watching from midnight on November 14th, to 2h. a.m. on the 15th, I caught a very few, perhaps not half a dozen, little flashes in the moonlit sky: the next night, and early morning, 15th—16th, were densely cloudy at the place whence I write; while I could not detect a single meteorite near midnight on the day last named. Nor, judging from the newspaper reports, do observers seem to have been much more successful anywhere, either in this country or abroad. The message from Berlin speaks of their having been "seen in large numbers," and then goes on to say that about thirty-one were observed during a six or seven hours watch! Astronomers in Philadelphia, the University of Pennsylvania, Chicago, Greenwich, Oxford, and Cambridge seem to have seen but little more. One hundred and two (only sixty-nine of them Leonids) in three or four hours being the maximum recorded. It would be simply idle to describe this as anything of a display, because in 1866 thousands and thousands of meteorites rushed across the sky, which actually seemed to be snowing fire. One is tempted to wonder what has happened. Has the nucleus of the ring become disintegrated, and are we never again to have such an awe-inspiring exhibition as that of 1866? Is there any mistake about the period of these bodies—or what?

And, apropos of the expected shower, I am sure that a large number of those who will read these lines will be in accord with me in sympathising with my friends Mr. and Miss Bacon in the exciting and most perilous experience they had in their attempt to observe it from a balloon. That they should have been, as they undoubtedly were, so near their deaths in their venturesome journey, and that the young lady should have broken her arm in their terrible descent, must excite at once pity and admiration for those who bravely faced the danger of a balloon ascent in the middle of the night, solely in the interest of astronomical science. Scientific men in general, and members of the British Astronomical Association in particular, will couple such pity and admiration with the heartiest congratulations to both father and daughter that they are safe and sound on terra firma again.

I scarcely wonder at a more or less ignorant sub-editor perpetrating the heading to which "B.Am A." calls attention (in letter 43021) on p. 315, inasmuch as the gentleman who appears in such unwarrantably borrowed plumes there has really so advertised and puffed himself, both anonymously and *proprio nomine*, that I really believe that 85 per cent. of the non-scientific public are in doubt whether he or Sir Robert Ball is the Astronomer Royal! That that most important and dignified post is occupied by Mr. W. H. M. Christie, C.B., seems to come as a kind of revelation to an overwhelming proportion of the people in society to whom one sits next at dinner. The head of that scandalously costly South Kensington job, the (so-called) "Solar Physics Observatory," has as much, or as little, claim to be the Astronomer Royal as I have—neither more nor less, and most assuredly I shall occupy that position quite as soon as he will.

[Moreover, as an addendum to what I have here said, I may, perhaps, mention that the Report of the Madras Observatory for 1898-99, which has only reached this country since the above was written, contains one paragraph of so remarkable a nature as to deserve a wider publicity than it is likely to obtain in its present form; illustrating as it does the kind of "advice" that a non-scientific Government apparently seeks, even if, as in the case to be referred to, it disregards it when given. It is the 6th section of the Report, and in it the Government astronomer, Mr. Michie Smith, says, under the heading "Kodaikanal Observatory":—"As mentioned in last Report, the Government of India requested the Astronomer Royal and Sir Norman Lockyer to report on the various Indian Observatories. The former, after visiting Kodaikanal, approved generally of the plans for the observatory there, and made some suggestions for minor alterations, which were at once adopted. Sir Norman Lockyer, on the other hand, without visiting the place, objected entirely to the plans, and on his return to England represented to the Secretary of State for India that the buildings were 'too costly and too permanent,' and generally were badly designed and unsuited for their purpose. He went on to point out that "the South Kensington Solar Physics Observatory thus equipped with temporary structures is the most powerful in the world. It does more and better work than the similar institution at Potsdam, where the buildings cost £250,000,' and urged that the new buildings at Kodaikanal should be like those at South Kensington, 'shanties' built of wood and canvas. As a consequence, the Secretary of State telegraphed out that the work on the observatory was to be stopped till the reports of the Astronomer Royal and Sir Norman Lockyer had been duly considered. To anyone acquainted with the climatic conditions existing at Kodaikanal the proposal to house valuable instruments in such 'shanties' as Sir Norman Lockyer recommended seems as strange as his estimate of the relative values of the work done at South Kensington and Potsdam, and the Government Astronomer protested strongly against his proposals. Whether or not this protest was forwarded to the Indian Observatories Committee is not known; but the result of the deliberation of the committee was that no reference whatever was made to the buildings, and after a delay extending from the beginning of June to the end of October, the buildings were allowed to go on according to the designs which had been so strongly condemned." It seems almost needless to comment on these words of the Indian Government Astronomer; but if, or when, his Report reaches Potsdam it is easy to picture the amused contempt of Drs. Vogel, Spörer, Lohse, and their *confrères* at an impudent attempt at self-advertising at their expense which might well turn Beecham, Pears, and Holloway green with envy.]

Premising that I have never seen Peck's "Observer's Atlas of the Heavens" in my life, and know nothing at all about it, I may tell "G. J." (query 97060, p. 325) that while Rigel is permanently of the 0·3 magnitude, that of α Orionis varies from 1 to 1·4 at irregular intervals. I have never myself seen Betelgeuse brighter than Rigel, and my experience is a fairly extensive one.

If "Hinel" (query 97072, p. 325) will reflect that the ultimate direction of the particles of a shell must be compounded of its rotary motion, which, of course, it never loses, and those of the fragments dispersed by the bursting charge, he will see that as these latter are incalculable, the paths of the segments must *ex necessitate* take all imaginable directions when it explodes.

In reply to query 97077, p. 325, the best educated people do *faintly* aspirate the *h* in such words as which, when, and why; albeit your average middle-class Cockney invariably renders them as witch, wen, and wye, as though he were speaking of a sorceress, goitre, and a familiar Welsh river. Sure is pronounced shure (to rhyme with pure). I am grieved to be obliged to add, though, that there is at present in society an affectation of clipping and distorting words; and that you hear but too many Johnnies and grand ladies talk of goin' out, eatin' cowcumber, and the like.

The *Philosophical Magazine* for November contains a very remarkable paper by Dr. G. Johnstone Stoney, F.R.S., entitled a "Survey of that Part of the Range of Nature's Operations which Man is Competent to Study," which is well worth careful attention as indicating more or less the limits of human knowledge. It will amply repay the serious study which it alike deserves and requires to be appreciable and intelligible to the student.

We have yet another illustration of Mr. Garbett's unfortunate habit of arguing merely for victory (in letter 43051) on p. 340, where, speaking of the (mythical) destruction of Sodom and Gomorrah, he says: "The date of the event is correctly given in Ussher's notes to Genesis as 1896 B.C." Now I would ask any one of my brother readers to turn back to Mr. Garbett's recent letters on cognate subjects in these columns, and to note how systematically he condemns and repudiates Ussher's chronology when it conflicts with his wild assertions concerning patriarchal history. When, however, he can twist ascertained facts into anything even apparently corroborative of his own nonsensical interpretation of history (?), then the despised Ussher is promptly erected into a valuable authority. I prefer not to comment on the impertinence of the allegation: "So Leverrier's origin for the Leonids in A.D. 126 is utterly disposed of." Garbett v. Leverrier!!!

In reply to Mr. Allison (letter 43057, p. 340), I know of no other cause than that of a change in the obliquity of the Ecliptic (which absolutely certainly exists) for the change of azimuth in the point of sunrise at the summer solstice. According to Stockwell, the limits of the obliquity are 21° 58′ 36″ and 24° 35′ 58″—i.e., its range = 2° 37′ 22″. Of course, all such calculations as those of Prof. Petrie and Mr. Whitmell must be made on the assumption that the "pointer-stone" was originally orientated with mathematical accuracy from the "altar-stone," and that the present apparent change of azimuth in the point of sunrise on Midsummer Day is really and truly an actual one. It is well known that the whole neighbourhood of this wonderful monument is crowded with tumuli, there being some 300 of them within a radius of three miles, *while the rest of the county is comparatively free from them*. Now, if Mr. Allison will turn to pp. 115 and 116 of the second edition of Sir John Lubbock's "Pre-historic Times," he will find that eminent authority pronouncing his opinion, founded on the nature of the contents of such of these grave-mounds as have been opened, that Stonehenge must date from the Bronze Age, which would put the date of its erection many hundreds, not to say possibly even thousands, of years before A.D. 400 or 425 either. Unfortunately, the merely astronomical data are both vague and questionable, owing, as I have previously hinted, to the vagueness of our knowledge of the original mode of determination of the orientation of what I may call the fiducial points of measurement. Were we entirely certain that the azimuthal direction, from some fixed point, of sunrise on Midsummer day, was determined with absolute precision by the builders of Stonehenge, the calculations of Prof. Petrie and of Mr. Whitmell would be conclusive, as coming from men of their scientific standing. But ——? Bear in mind this is a question of seconds of arc.

Will Mr. McDowall (letter 43070, p. 342) tell us *why* it is "premature to assume that we have reached the turning-point of the sunspot curve?"

"F. J. G." (97094, p. 345) will not improve upon a tin tube for a dewcap. But it must be kept bright outside, and must be long enough.

A Fellow of the Royal Astronomical Society.

OBSERVATIONS OF THE LEONIDS, 1899.

[43074.]—The following table shows the watches kept:—

1899.	From.	To.	Meteors Seen.	Meteors Rec'rd'd	Leonids Seen.	Leonids Rec'rd'd	Seeing.	Notes.	Hours of obs.
	h. m.	h. m.							
Nov. 8	16 0	17 45	13	13	0	0	1	—	$1\frac{3}{4}$
" 9	—	—	—	—	—	—	-	Sky cloudy	—
" 10	16 30	18 0	3	3	0	0	4	Sky exceedingly poor	$0\frac{3}{8}$*
" 11	—	—	—	—	—	—	-	Sky unobservable	—
" 12	—	—	—	—	—	—	-	Sky unobservable	—
" 13	17 0	18 10	2	2	0	0	4	Sky very poor; observation only possible at intervals ..	$0\frac{1}{4}$*
" 14	—	—	—	—	—	—	-	Unobservable	—
" 15	13 15	17 15	16	11	10	7	3	Moon up during whole watch	4

* Time of actual observation.

In the above table, under the heading "Seeing," the following numbers are used: 1, seeing very good; 2, good; 3, fair; and 4, poor.

During the whole period of observation (eight hours) there were $6\frac{1}{4}$ hours of clear sky. Thirty-four shooting-stars were seen, and 29 registered; of these, ten were Leonids, and seven of these latter meteors were mapped.

Nov. 13.—Master R. Lamming, of Leicester, watched the sky after 12h. throughout the night, but reports that clouds prevented observation of meteors.

Nov. 14.—A large number of people here stayed up all night in hope of witnessing an abundant shower. According to accounts, the sky cleared for a short time soon after midnight, and six meteors were seen, one of which, nearly as bright as the moon, "fell down slowly from Leo." However, from what I can gather, the shower was not of the expected strength.

Nov. 15.—The evening promised very badly at first. Mr. G. W. Cook, of Rearsby, and myself were observing at this place, a village seven miles N.E. of Leicester. Soon after midnight the clouds became very broken, and at 13h. 15m. we were able to commence observations. We took up a position on a hill in order to get above a low mist. Here we had an uninterrupted view all round, and the sky remained clear throughout the rest of the night, except on one occasion when a mist drifted over for a few minutes. Meteors came slowly. In the first hour only six were seen (four Leonids). The maximum was placed in the fifteen minutes between 14h. 0m. and 14h. 15m., when three meteors (two Leonids) were observed. In the half-hour 14.45 to 15.15 only one shooting-star—a Leonid, by the way—was seen. From 15h. 15m. to 17h. 15m. only five meteors were counted. Of these three were Leonids. At 17h. 15m. we abandoned the watch, although the sky was still very clear. The horary rate of the Leonids works out to 2·5. It is very probable that many fainter meteors escaped recognition, owing to the bright moonlight.

On projecting the Leonid paths, I find a radiant diffuse to the extent of 4°, with its centre at α $151\frac{1}{2}°$ δ + 22° (seven meteors). They were all very swift, but only one was recorded as having left a streak.

Minor Showers.—Other minor radiants were observed as follows:—

Radiant Point.	No. of Meteors.	Appearance.	Nights of Observation.	Name.
α δ			1899.	
$132° + 45\frac{1}{2}°$	4	Swift	Nov. 8, 15	*i-k* Ursids
160 + 11	4	Swift; streaks	Nov. 8, 10, 13	α Leonids

Leicester, Nov. 24. **A. King.**

[43075.]—I notice in Mr. W. H. Daw's letter (43046) on p. 338 that on the morning of Nov. 15, between 4.30 and 6, he saw a meteor near the radiant point, which he describes as bursting out into a blaze of light of fully a quarter of a degree in diameter, and after going out leaving a haze somewhat resembling a comet. As I had a somewhat similar experience that morning, it would be interesting, as possibly throwing fresh light on our knowledge of the extent of the atmosphere, to know whether this meteor, which he saw in London, was the same as the one which I noticed up here in

North Ayrshire. For the purpose of identification I quote from my notes made at the time: "Leonid (?) 2nd magnitude, yellow, 4.50 a.m., no motion, blazed out like a star between μ and ε Leon. Maj., lasted about one second or slightly longer, left no trace." If the time and position were the same, it is possible that they were the same meteor, as the discrepancies in the other particulars might be accounted for by our personal equations. On the other hand, it seems impossible with the *estimated depth of the atmosphere* that the same meteor should appear to be coming straight towards the eye of two persons at a distance of something like 400 miles apart. With regard to the time (4.50) I should mention that in verifying my watch next day by the station clock, I found that I was rather more than half a minute fast; but as I have since had reason to doubt the accuracy of the station clock more than that of my watch, I prefer to give the time as I recorded it, though the former was said to have been set to G.M.T. at 10 o'clock that morning.

I kept an intermittent look-out for meteors from 11.30 p.m. Nov. 14, going out for about five minutes every half-hour or so, but saw nothing till 4.2 a.m. (Nov. 15) when I saw a Leonid. As there was a strong and very cold N.E. wind blowing I went back and prepared myself for a longer vigil, returning to my post about 4.15; and between that time and 5.25 I saw eleven other Leonids, including the one described above, which I marked (?) owing its distance from the true radiant, and four other meteors belonging to other radiants. The Leonids were all swift, but only four left any trail; they varied in magnitude from 2nd to 4th; their colours were white (or more strictly bluish-white), yellowish-white, yellow, and (one) orange. The other meteors were all comparatively slow; two were of 2nd mag. and two of 4th mag., and in colour two were orange, one yellow, and one white. There was very little cloud after midnight, and none after 4 a.m. On the next few nights the sky was completely overcast with dense hazy clouds.

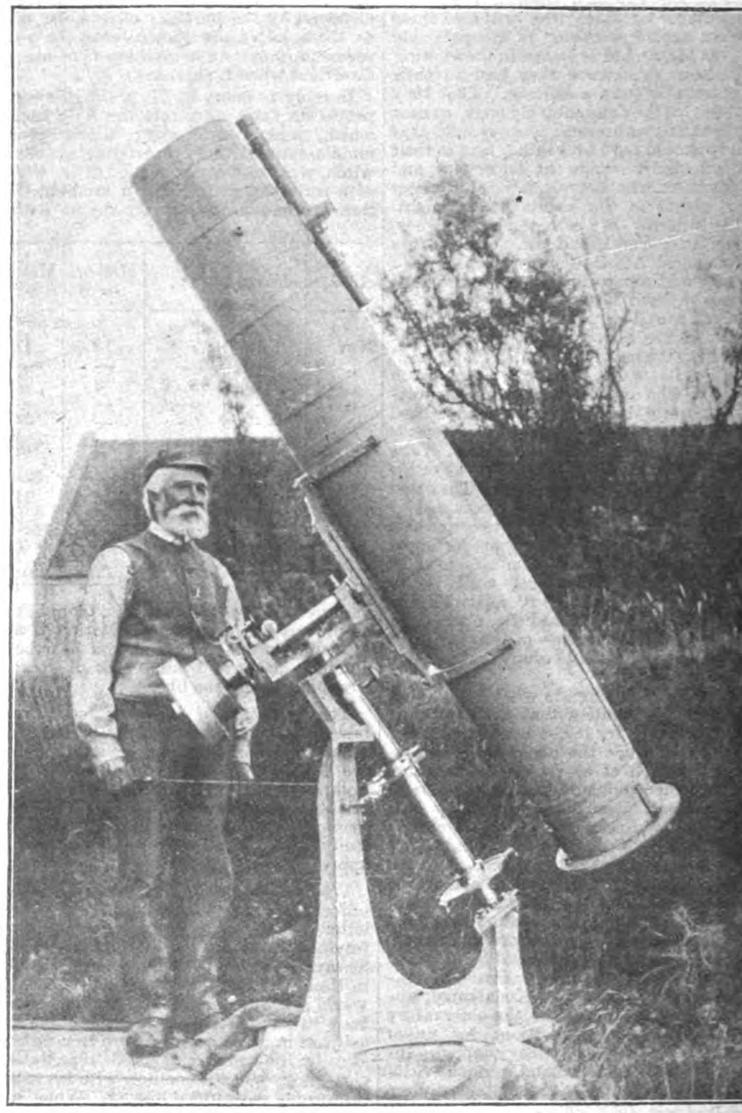
N. Maclachlan.

Routenburn, Largs, Ayrshire, Nov. 25.

THOSE DANGEROUS LEONIDS.

[43076.]—Might I suggest to Mr. Garbett that the stones which slew the Canaanites on the day of the battle near Gibeon were Leonids, and that it was the blaze of the shower (which was equal to the light of the sun) that led to the belief that the sun was standing still? Perhaps he will find something to this effect in the pages of Comte, though if the latter only knew of four asteroids in the year 1850, I should not rate his astronomical knowledge very highly.

W. H. S. Monck.



A FINITE UNIVERSE (?)—THE DESTRUCTION OF SODOM—COMETARY ASTRONOMY.

[43077.]—When all has been said on the subject of a finite universe, it must still remain a matter of opinion as to whether the universe is finite or not. It cannot be proved one way or another. Whatever limit may be set, we always want to know what is beyond that limit. Myself, I see no reason why infinity should not be. There is always the possibility, nay, the probability, of the existence of stars so remote in the space that their light, though it started perhaps before the earth was formed, has not reached us yet. When a new temporary star blazes out, people are apt to forget that the cause of its sudden appearance is not in operation at the moment of appearance, but hundreds or thousands of years before. Were the stars infinite in number, they would not necessarily cause the sky to appear a blaze of light. The enormous distance of the more remote of them, the enormous time their light would take to traverse the distance, and the presence of dark bodies in space shutting out the light of a certain proportion of them, would account for their not all being visible.

One hesitates on the momentous question of the destruction of Sodom. Possibly London is in danger of destruction by the Leonids on each Nov. 15. If so, it is a blessing that the great autumn shower failed to put in an appearance. The ludicrous spectacle of Lot's wife standing (43051, p. 340) under a falling meteor composed of salt can only be provocative of derision. To make these assertions, however ingenious they may be, "E. L. G.," is one thing; to prove them is another. I fail to see that Leverrier's origin for the Leonids is "so utterly disposed of."

I thank "E. L. G." (letter 43062, p. 341) for his instructive quotations; but it does not go to say that we are to study "sun, moon, and comets" only. Suppose a comet to be in such a position as to make its collision with the earth inevitable. What could we do? We could not prevent the catastrophe. And suppose that the earth did encounter a comet, would not the comet come off worst? Mr. Hind, one of the foremost authorities on comets, said that on June 30, 1861, the earth actually passed through the tail of the great comet of that year, and on that day several observers noticed a peculiar phosphorescent glow in the sky. Did anything happen? No. There was no geological catastrophe. The whole mass of a comet is comparatively small—so much so that, even supposing one did collide with the earth, no harm much, if any, would result, except to the comet.

Earlsfield, S.W. Silverplume.

IS THE UNIVERSE FINITE?

[43078.]—When so competent a judge as Mr. Monck pronounces the arguments in letter 43023 invalid, it requires some temerity on my part to advance anything further to support them. But it seems to me of prime importance, in connection with the intensity of light received by the earth, that the solar surface may be regarded wholly of the same distance from us when compared with the great diversity of stellar distances in any portion of the heavens of like area.

Given a star of a certain magnitude, four others of the same kind at double the distance, or nine at treble the distance, might double the light we receive from that portion of the heavens, whilst doubling the effulgent area. Hence, if the intensity of the hypothetical light reaching us from an invisible star required doubling before any sensible effect was produced on the retina, it is obviously possible that the eye might become aware of the luminosity of a disc-area doubled thus. But the probability of a disc-area being doubled by four, or nine, or other small number of stars is remote, on account of the diversity of distances between the stars. There is, I think, reason to believe that few stars are separated from others by a less distance than that between the nearest of them and the sun. Let us, therefore, imagine a series of about equal size occupying much the same apparent position in the heavens. The intensity of the light from the direction of star A must be doubled to insure visibility. Star B on its farther side reinforces A by a fourth; star C on the farther side of B helps A with a ninth more; star D adds a sixteenth, and so on. Admitting the reinforcing stars to be arranged spirally round A in a space not exceeding A's area, how many such stars would be required before the requisite duplication of the intensity be attained? And if it were needful to treble or quadruple the intensity, how many?

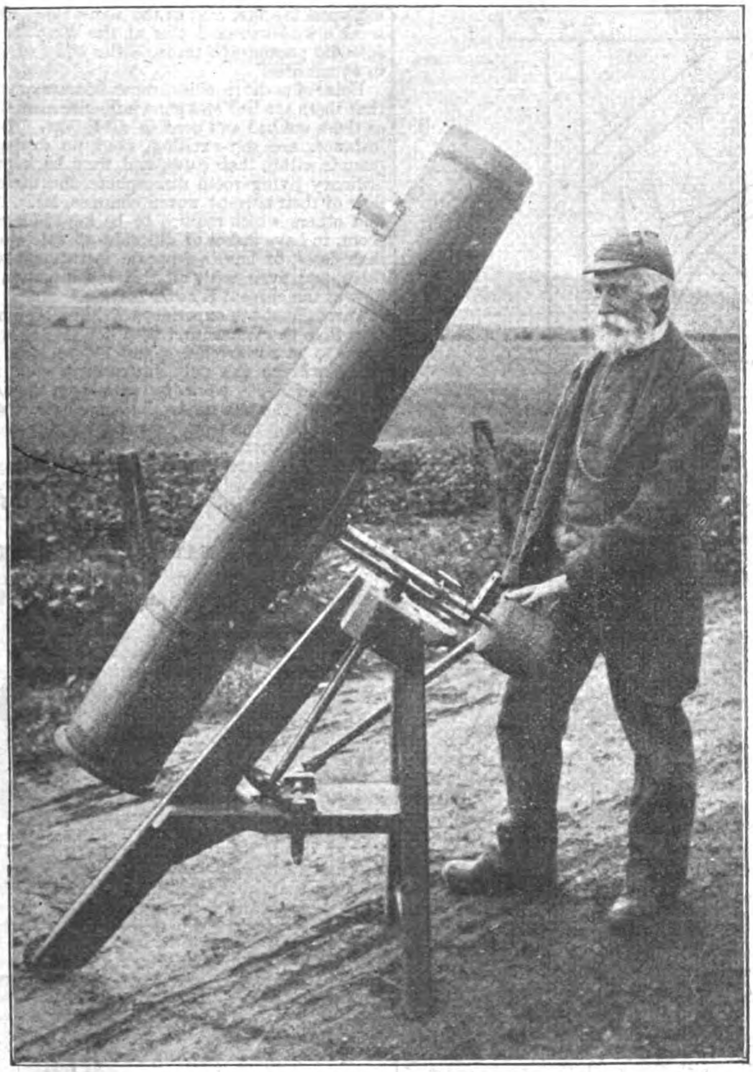
Again, a certain number of stars are visible on a photographic plate which are indiscernible to the eye even with the aid of the best telescope. The light from one of them takes perhaps hours to affect the sensitive emulsion; yet can we be certain that the work then done is the operation of a single star? Is it quite out of the question that that tiny speck may be due to the action of light from a multiple-disc area whose components are irresolvable? Indeed, I do not realise any absurdity in supposing that some dark spaces in the heavens are possibly due to the hypothetical light reaching us too feebly to affect retina or plate, which, I take it, means to us that any stars which may exist in such obscure regions are at an infinite distance from the earth. By "infinite" I understand that which our faculties do not allow of our measuring, counting, or even estimating. I use the word somewhat agnostically, so to speak, as an expression connoting compusory human ignorance, not as an absolute negation of limit. Frankly, I find it easier to picture generations of men striving to reduce the universe to a row of figures than to realise some outer star as the first milestone from void space.

J. Dormer.

A WORKING-MAN ASTRONOMER AND HIS TELESCOPES.

[43079.]—As matters pertaining to the telescope appeal to a very large number of your readers, I have much pleasure in sending you a brief account of some very creditable work which has been done by one of your oldest subscribers, with no other assistance than that derived from the pages of your Journal, and under surroundings by no means congenial to the pursuit of such hobbies; indeed, when the whole circumstances are taken into account, the results accomplished by this working man stand out as examples of pluck and perseverance seldom to be met with.

Mr. John Glass, who follows the occupation of a meal miller in a somewhat isolated glen a few miles from the village of Tarland, in Aberdeenshire, has been a somewhat constant reader of your valuable publication almost from its commencement. The



"E. M." has been one of his best friends, and few have perused its pages with greater interest or profit.

About twenty years ago, Mr. Glass set about the construction of a small pipe-organ from the articles which appeared from 1870 to 1874, and contributed chiefly by "J. D." and "An Adept." This instrument, which is 7ft. wide, 8ft. high, and 30in. deep, has 198 pipes and three stops—viz. Stopped Diapason, Open Diapason, and Wald Flute—while an octave-coupler upwards with twelve added pipes practically gives Stopped Flute, Principal, and Piccolo. I have very little knowledge of organ matters; but those better able to judge have expressed admiration of the tone and capabilities of the instrument.

Mr. Glass next directed his attention to the astronomical telescope. He had taken an interest in astronomy for many years, and longed to have an opportunity of examining the more prominent celestial bodies through such an instrument. There was, however, nothing of the kind available, and he resolved to make one—a task which was rendered all the more difficult from the circumstance that he had never seen a telescope of any kind. Having first carefully studied the valuable letters by the late Mr. H. A. Wassel on "Grinding and Polishing Glass Specula," which appeared in your pages between 1881 and 1886 (Vols. XXXIII. to XLII.), and the article on "Testing Specula" by Messrs. M. T. Tydeman and H. Parker, which appeared in 1871, he next made a polishing and grinding machine according to the directions given by the first-named contributor. The size of mirror fixed upon was 6in., which was worked to a focus of 5ft. It was mounted as a Newtonian on an equatorial stand of simple construction, and, with the addition of a flat and a few eyepieces which were supplied by Mr. Linscott, Mr. Glass found himself in possession of an instrument of which he was justly proud. At a subsequent date (June, 1893) the speculum was resilvered by the optician referred to, and was pronounced by him to be "very good indeed."

Mr. Glass has been so pleased with the success which attended his first effort, that two years ago he decided to make a telescope of larger aperture. He procured an 8in. disc, which was worked to a focus of 80in. This mirror, the actual focus of which is 79½in., is beautifully figured, and gives very fine results. It has been mounted on an equatorial stand, which would do credit to a skilled optician. This stand is fitted with 8in. gunmetal R.A. and Declination circles, the former being divided to 4m. and the latter to 1°, and reading to 12s. and 3m. respectively. The design for the stand was taken from a drawing, which appeared in your issue of August 16, 1872, by your old and valued contributor "F.R.A.S.," who at that time communicated two articles on the equatorial and its adjustments, and who will no doubt be pleased to learn that his drawing has been utilised to such advantage. As the articles referred to will show, the design was intended for a refractor; but, with a few alterations, it makes a capital stand for a reflector as well. When bolted to the base it is exceedingly rigid, as I can testify from personal examination, and by hand-driving I found, even with a high power, that the image was quite steady.

Mr. Glass has almost completed the erection of a small observatory for the 8in. instrument, and we may hope he will spend many a pleasant evening under its roof.

I inclose photographs of both telescopes, and next week hope to send you a photograph of the grinding and polishing machine. The principle on which its utility depends and the various movements are practically the same as recommended by Mr. Wassell, but in minor details Mr. Glass has been able to effect a number of improvements.

Dalbeattie, Nov. 10. Alex. Smith.

THE ABSORPTION OF STARLIGHT.

[43080.]—MR. BURNS's reasoning on the absorption of starlight seems to be inconclusive. The question whether the ether may not absorb light and heat is not touched on, and the assumption that radiant heat is proportional to radiant light rather begs the question at issue. If there is an obstructing medium which intercepts the light of distant stars, it probably absorbs this light, and gives out the same amount of energy in the shape of dark heat. This seems to be, in fact, what our atmosphere does.

From the small amount of the total starlight compared with the sunlight, Mr. Burns infers that space is too cold for gases to exist in it. But, in the first place, the total starlight is different at every point of space, and, in the neighbourhood of rich clusters, for example, it is probably very different from what it is just outside of the limits of the Solar System. But, in the next place, large patches of the sky are covered with gaseous nebulæ, and with better instruments, or more careful research, we are constantly discovering more. These are in a state of incandescence. May we not reasonably suppose that there are many others whose temperature is not so high as to render them visible?

Nor do I think Mr. Burns is much more successful in dealing with the question of cosmical dust. The assumption of a universe eternal as regards past time, but finite as regards space, is likely to land us in some startling conclusions, and I think his reasoning might be equally employed to prove the impossibility not only of meteor-showers, but even of asteroids—and I may add that bodies as large as the asteroids would be properly classed as cosmical dust for the present purpose, provided that they were far enough away from us. Indeed, the earth itself would answer for the same purpose. But Mr. Burns's theory of the gradual destruction of cosmical dust at all events only holds good in case there is no way of replacing it. Yet we only require a volcanic eruption somewhat more violent than usual in order to generate cosmical dust ourselves, and if there is a volcano on one of the asteroids, we may regard the generation of cosmical dust as certain.

The two theories of cosmical dust (i.e., dark bodies in space) and gases should not be regarded as opposed. Very likely the distant stars in some directions lose much of their light owing to the interposition of invisible nebulæ, while in others they lose it owing to the interposition of solid dark bodies. That considerable diminution of starlight is sometimes caused by both of them, seems to me pretty certain. But whether this takes place over the whole (or the greater part) of the sky, is a different question. W. H. S. Monck.

THE MOON AND THE WEATHER.

[43081.]—THERE is a terrestrial pulsation, the intervals of which are, as nearly as I can make out, $7\frac{1}{15}$ days. At the end of each interval the weather may change; but as the change also depends on various meteorological conditions, this is not always noticed. The effect, however, on animal life and vegetation is very marked. The moon being, physically speaking, a limb of the earth, is governed by it, and is full at the end of an interval. It is perhaps natural that the moon is often saddled with the responsibility of any change in the weather which takes place at the time.

J. H. Schucht.

SEEING BY WIRE—DIRECT POSITIVES—THE PLANETOIDS — EXPERIMENTUM DOCET.

[43082.]—A FEW weeks ago there was mentioned in these columns a popular magazine account of a Polish inventor's method of "seeing by wire." As there seems to have been a little embroidery in this description of Messrs. Szczepanik and Kleinberg's telectroscope for electrically transmitting photographs, &c., it may be worth mention that this apparatus was described at length in the *British Journal Photographic Almanac* for 1899, and elsewhere.

A method of obtaining a positive direct on ordinary plates (which was the subject of a query here a short while ago) has been suggested by Dr. Scott Lauder. The negative image is first developed, then removed by persulphate of ammonia, and the remaining bromide, after a brief exposure to light, is developed. The results, however, are, so far, not very satisfactory.

Without, I hope, indulging in carping criticism, I suggest that there is a slip in Mr. Garbett's letter, 43062. Before 1850 ten minor planets had been discovered, which number was trebled by the year 1854, when the "Politique Positive" was completed.

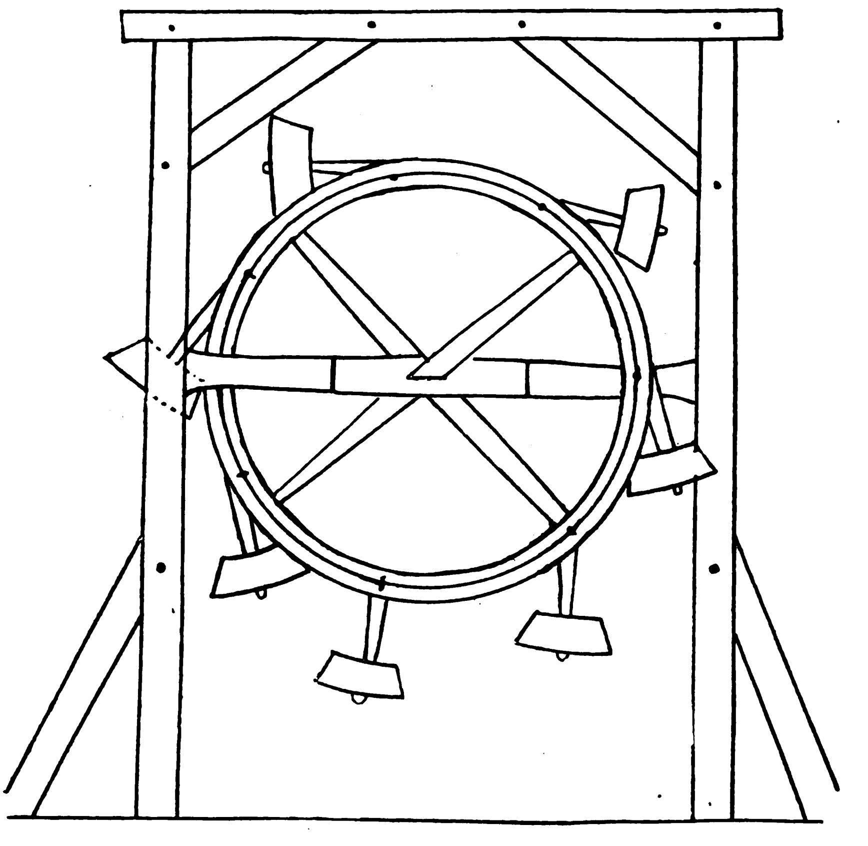
The writer of letter 43067 appears to sincerely believe scientific men obtain their convictions without experiment. One can only hint that without rigid tests of this description, one may fall a victim of strange errors. J. Dormer.

LATHE MATTERS.

[43083.]—SEEING your correspondent (letter No. 43043, p. 319) asking for particulars of Britannia Co.'s No. 16 screw-cutting lathe, I should like to say that I have had one in use for some years (the 6in. centre, 6ft. bed), and can assure him he can do plenty of useful work with the foot gear as supplied with the lathe. I have cut square threaded screws 1¼in. dia. easily (by foot, of course), using the back gear. M. S. Don.

[43084.]—I WOULD advise "Screw Cutter" to buy a good 4½in. or 5in. screw-cutting lathe by one of our Manchester makers—a proper mechanic's tool. He will then get good value for his money, and have satisfaction in working same. Also have the usual four bolts on top of slide-rest for holding tools. I am using a 4⅝in. back-geared Manchester lathe, and do not consider it hard work at all.

J. A. C.



GILBERT'S NEW POWER MACHINE.

[43085.]—SEEING that the hardy perennial (letter 43036) Perpetual Motion has cropped up again in the weighted-wheel shape, I have photographed the original drawing of what must be very near its earliest example. The page photographed is from the sketch-book of Willars de Haricourt, preserved in the Bibliothèque Nationale, Paris (Ms. Fr. 19093).

H. H. S.

FLYING-MACHINE.

[43086.]—R. F. MOORE, in his answer to Roderick D. Hall (43038), states that the difficulty in all flying-machines is to get a sufficiently simple and light motor. Now this, even according to his own showing, is not in accordance with actual fact; for let us suppose for a moment that he is somewhat near the truth when he suggests that 1H.P. of force would be sufficient to raise 100lb. in weight into the air, or, as he says, fly 100lb. in weight. Always bearing in mind that before you can fly 100lb. in weight through the air, you must first get it there. This is a fact too often forgotten by men who seem to strain every nerve and their imagination to create a machine that shall fly through the air at some fearfully sharp rate of speed or other. A flying-machine that cannot travel through the air at all speeds from 60 or 80 miles down to one mile per hour will be both useless and dangerous. This simple fact, I fancy, any man will see at once. But to return, Mr. Moore assumes that 1H.P. will fly 100lb. This, I will suggest to him, will be splendid work, and, if true, solves the problem at one, as engines both strong and light have already been made and can be made again in any numbers, under 15lb. to the horse-power, this leaves the very respectable figure of 85lb. as spare weight that the said engine or motor could raise. However, I am afraid that on the principle of the screw, this is hardly correct—at least, it has never been proved, I think; but here I would point out the fact that seems not to be recognised—that the bird uses the screw principle for propulsion only, and that there is a mechanical principle involved in the operation of flying other than that of the screw, and more important in many respects, because, were it not for this other principle, the safety of the bird could no more be insured than the safety of Mr. Maxim's machine could be insured if it should be sent into the air. The wing of the bird works out in the air two distinct mechanical principles—the paddle and the screw. A close attention to its shape and its action in the air will show any capable man this. The grand principle that Nature shows us here seems to be: the paddle to suspend, the screw to drive or propel. Now it would be plain that the screw could not possibly do both at one and the same time; thus, sometimes the bird calls on the screw, and sometimes the paddle; at others, both principles together are required, as when flying through still air; in this case, no doubt, both principles about equally would be used by the bird; but in flying dead against the wind the screw only would be required, the wind being sufficient to support the bird's weight, while the wings being in this case, props artificially twisted and made for the time being to act entirely as screws, the paddle, as before mentioned, not being required. Now, singular to say, if the bird turns suddenly round and flies with the wind, the whole order of things would at once be reversed. The bird would now require the paddle and not the screw, because the wind would no longer tend to suspend the bird's weight, but would tend to drive it forward; in accordance, the bird would be compelled to drop the mechanical principle of the screw which it would no longer require, and take to the paddle in order to prevent its body coming like a stone to the ground, exactly as Mr. Maxim's machine would have done, or Prof. Langley's machine would do under like circumstances; for both these machines may be likened to a huge bird that can call into action the mechanical principle of the screw only. The fly the air either naturally or artificially requires the paddle as well as the screw. This fact most certainly must be reckoned with by any man who expects to imitate the bird. Mr. Moore goes on to say that as soon as we have a sufficiently simple and light motor, the design of the machine is a secondary consideration. This, again, most certainly is not in accordance with actual facts, as everything depends on the design of the machine and nothing else, and, as far as my own experience goes, the motor question has not received a moment's consideration scarcely. I am quite willing to leave that to others. I know there are scores of men both able and willing to provide me with a strong and light engine or motor, therefore I have given my whole attention, lasting upwards of 30 years, to the one thing needful—getting at the secret of aërial flight, how to form the mechanism that is required to act on the air as the birds' wings act; in short, to imitate the bird. And it is through this fact that I am enabled to state, without fear of contradiction, that whenever the flying-machine appears, it will be founded upon the same general principles as my own design is founded upon, because it is founded upon the true principles that Nature shows us must be adopted if we are to fly and carry weight through the air with power, and, above all, with safety.

Thomas George Challis.

STATICAL MACHINES FOR X-RAY WORK.

[43087.]—ON p. 341 your correspondent "M." (let. 43064) refers to the time required to obtain a negative taken through a thick part of the body.

It may be well for your readers to know that I have seen photographs with good detail taken in a few seconds, and others in a few minutes, depending upon the age, &c., of the individual. This last week a well-known doctor at the West End took a splendid photograph through the body of an adult in 4½ minutes.

Users of static machines must, however, remember that there are bad and good influence machines, just as there are bad and good in all things. Some, for instance, are self-exciting, need no drying compounds within their cases, and may be kept in any ordinary living-room atmosphere, the direction of flow of their current never changes, &c. Then we find others which require to be kept in a very dry room, to have dishes of chloride of calcium within their cases, to have a separate instrument to excite them, and even with all this the direction of the flow of the current is never certain.

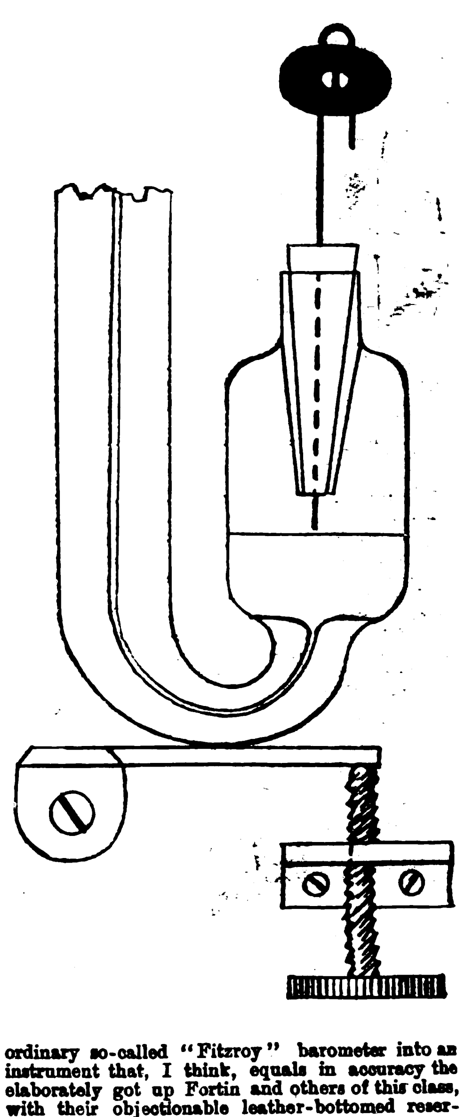
Throughout my experience I have seen no other type than the Wimshurst used for X-ray work; it seems to be *par excellence*, and before long it probably will be the only instrument used for the purpose of X-ray work, for with them the exposure is shorter; there is no troublesome battery or noisy coil, and they run from year end to year end without a penny cost.

Intending users, therefore, should be careful to know that their selection is of the right type, or the investment may lead only to regret.

J. W.

CONVERTING FITZROY BAROMETER.

[43088.]—I SEND you a drawing of a simple method I adopted some years ago of converting the



ordinary so-called "Fitzroy" barometer into an instrument that, I think, equals in accuracy the elaborately got up Fortin and others of this class, with their objectionable leather-bottomed reservoirs, &c. All that is required is to relieve on one side the brass bands that fix the tube upright so as to allow it to move freely up and down by means of the screw working against the plate on which, you will see, the barometer tube rests. The surface of the mercury in the bulb can be readily brought into contact with the point of the wire before the reading is taken as usual. The small paper funnel through which the index wire (steel, iron, or platinum) passes answers the double purpose of guiding the wire, and also effectually preventing any loss of mercury when at any time the barometer is carried from one place to another by a careless person. It may be carried in any position without injury. This funnel is made of paper rolled into shape with gum or glue, and when dry the point is snipped off, so as to allow the wire to pass through freely. It fits

tightly any size or shape of mouth of bulb. From the point of the fixed wire to the scale at the top, of course, measures 27, 28, &c., inches.

Aberdeen. **Alex. Reith, M.D.**

MEAN-TIME DIAL.

[43089.]—If "A. S. L." (letter 43063) will kindly look up back number, 9th (?) Sept., 1887, he will find the simplest method of making a mean-time sundial. G. D.

REPLIES TO QUERIES.

*** *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[96864.]—**Knocking in Gas-Engine.**—A gas-engine, if properly constructed—i.e., the small end fitted in the piston a knuckle-joint, it did not ought to play pranks in a lifetime. Take it out, and get a piece of pen steel. Punch or drill a series of small holes in it, and bend it around the pin for a bush. Now, having made that a nice snug fit, lap your joint out that you make a good fit, cut off bush a little bit shorter than width of joint, and put back in its place. But if it is not fitted properly with a good joint, it will kick again.

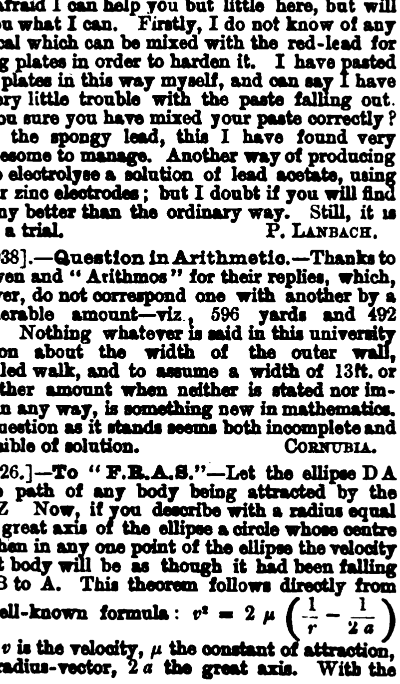
JACK OF ALL TRADES.

[96884.]—**Zincos.**—There are several works on the method of producing "zincos," which have really nothing to do with "printers," except that they are supposed to produce a "work of art" from them. They are simply etched plates of zinc. The drawing is transferred to, or is photographed on, the zinc, and then the parts that are not wanted are eaten away by acid (hydrochloric). The query has been answered many times, and any bookseller can supply a work on the subject, for there are several. Try Dawbarn and Ward, Farringdon-avenue, E.C. PROCESS.

[96912.]—**Pasting Accumulator Plates.**—I am afraid I can help you but little here, but will tell you what I can. Firstly, I do not know of any chemical which can be mixed with the red-lead for pasting plates in order to harden it. I have pasted many plates in this way myself, and can say I have had very little trouble with the paste falling out. Are you sure you have mixed your paste correctly? As to the spongy lead, this I have found very troublesome to manage. Another way of producing it is to electrolyse a solution of lead acetate, using lead or zinc electrodes; but I doubt if you will find this any better than the ordinary way. Still, it is worth a trial. P. LANBACH.

[96938.]—**Question in Arithmetic.**—Thanks to D. Owen and "Arithmos" for their replies, which, however, do not correspond one with another by a considerable amount—viz., 596 yards and 492 yards. Nothing whatever is said in this university question about the width of the outer wall, gravelled walk, and to assume a width of 13ft. or any other amount when neither is stated nor implied in any way, is something new in mathematics. The question as it stands seems both incomplete and impossible of solution. CORNUBIA.

[97026.]—**To "F.R.A.S."**—Let the ellipse D A be the path of any body being attracted by the point Z Now, if you describe with a radius equal to the great axis of the ellipse a circle whose centre is Z, then in any one point of the ellipse the velocity of that body will be as though it had been falling from B to A. This theorem follows directly from the well-known formula: $v^2 = 2\mu\left(\frac{1}{r} - \frac{1}{2a}\right)$ where v is the velocity, μ the constant of attraction, r the radius-vector, $2a$ the great axis. With the



parabola we have $2a = \infty$, and the velocity in the point A essentially corresponding to that which the body would come to while falling from an infinite distance, which velocity notoriously will not be infinitely great. If the body be to describe a hyperbola, its velocity at any distance from Z must be greater than if it be moving in a parabola. It must needs have been put into motion with some certain velocity. From our theorem at once follows that known thesis—viz., that the species of the conic section and the size of the axis $2a$ depends only on the quantity of velocity, and not on its direction.—DR H. W. SCHROEDER VAN DER KOLK, Mastricht, 1863, June 8."—Such is the translation of a theorem in *Astronomische Nachrichten* No. 1426. And now, gentlemen, "F.R A.S." and "Second Differential," up, up! Learn to read German!

Potsdam, Nov. 21. PROF. DR. E. LAMP.

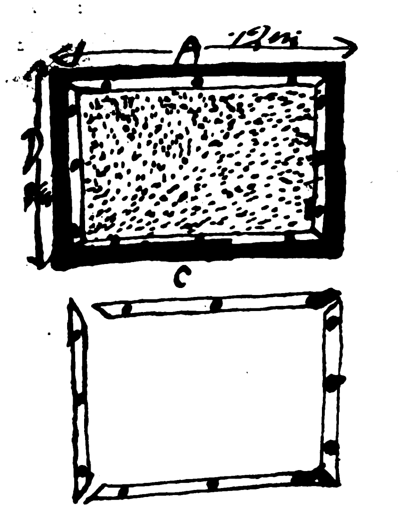
[97019.]—**To Mr. Bottone.**—Thanks for reply in query; but I would have preferred a Gramme or drum armature. Can neither of these be made as small as I require also?—as I can obtain 6 volts 2 ampères from an H armature 1¼in. long and 1in. in. diameter. I do not understand why to produce the same result from a three-legged armature it should have to be 2in. by 2in., wound with about thirty yards No. 22 B.W.G., for the efficiency of this latter seems very small; speed to be 300 revs.

F. C. CHASE.

[97034.]—**Trellis.**—The question of wind pressures on surfaces is still involved in obscurity to a very great extent. The Forth Bridge experiments showed that on a large continuous surface the pressure per square foot is always less than on small surfaces, which would point to the creation of eddies as being responsible for a part of the recorded pressures. The pull due to eddies would be proportional to the perimeter of the plane exposed, and would be smaller in proportion on large planes than small. Mr. Wenham's contribution some time since (not as a letter) on the effect of ribbing the under side of a plane surface seems to point in the same way. Probably, assuming equal areas exposed to same wind, there would be more pressure on the trellis than on the plane surface. Of course, above means solid surface, and not space occupied. THE BOGEY MAN.

[97046.]—**Steam Exhaust.**—The simplest method of condensing the exhaust steam from an engine is to inject it into the lower open end of a standpipe of large diameter. During the ascent of the steam it becomes mixed with a large body of cold air, and is effectually condensed and falls in a continual shower. The water is collected in a receptacle and returned to feed the boiler, which is thus kept free from incrustation. I have adapted this arrangement to several steam-engines, both portable and fixed. The air-pipe or flue should be of large diameter—not under 4in.; in fact, the larger the better. It may consist of cast-iron or stoneware pipes jointed with Portland cement. My first experiment was in use for several years, and consisted of nothing more than a square wooden shoot carried to the top of the building. This arrangement never caused the least trouble, and the updraught being low, no particles of water were projected from the top, from which no steam was visible. F. H. WENHAM.

[97047.]—**X Ray.**—Proceed as follows: Make a frame 12in. by 8in., as per sketch, with wooden



cleats ⅜in. broad, ⅜in. thick. The cleats should be sawn out from each piece of wood B (A, B, C, D), so that when the cleats, after having been sawn out, are placed into their former positions, they being flush with the surface of the wood from which they were sawn out. Having made the frame, a piece of good Bristol board should now be procured from the stationer's. This should be thick enough as to be absolutely opaque to ordinary light. Test this by holding up in strong sunlight with hand behind. This should be cut to right dimensions so to fit into frame. "Novice" should now procure from the chemist a highly fluorescent salt, called barium platinum cyanide, or, if "Novice's" pockets are not very full, he can procure an excellent salt called calcium tungstate. This can be got for about 2s. per ounce. He now takes his Bristol board, and pins the four corners to a drawing-board. Three or four drops of good gum-water should now be poured over the Bristol board, and, with a fine camel's-hair brush, spread the gum equally all over the surface of the cardboard. Any excess of gum-water should be immediately swept off by means of a good boxwood ruler pressed evenly on the board, and drawn from one edge to the other. Some of the calcium tungstate should be immediately sifted all over the gummed surface, taking care to spread equally, so as to leave no patches. The drawing-board should now be reared upon a clean piece of paper, and tapped with the hand. The non-adherent calcium tungstate can then be collected for another screen, if required. When dry, the screen can be placed into frame-cleats placed on top and fixed into position by means of bright round-headed nails, ½in. long, at each corner, and one in the middle. The sieve for sifting the tungstate of calcium can be made out of an ordinary tin with the bottom knocked out, and a piece of very fine muslin spread over the bottom, and tied securely around the tin with a piece of broad tape.

T. B. G.

[97049.]—**Ohm's Law and Decrease of Voltage.**—I fear none of your correspondents have given Mr. Brown much help by their answers. It is with the greatest hesitancy that I attempt to help him, the subject being closely allied to a definition of electrical potential, and I shall never forget the words with which the late Prof. Clerk-Maxwell once commenced his lecture on this subject. He said: "I shall to-day try and explain to you what is meant by electrical potential. I doubt if I shall succeed, because I believe that there are only three men who ever thoroughly understood what it means—I allude to Faraday, Thomson, and —and another." Neatly put, was it not? Before trying to answer Mr. Brown's query, I should like to point out that Ohm's law is too often stated as follows:—"The current is equal to the E.M.F. divided by the resistance." This, however, is not the law as Ohm's stated it. It is, so to speak, the Act of Parliament without the preamble. The whole law is as follows:—"When proper units are chosen for expressing the current C, the resistance R, and the E M.F. E, then the current is equal to the E M.F. divided by the resistance." This law is usually stated in the form $C = \frac{E}{R}$, and since this is an algebraic equation, it is equally true that $E = CR$ and $R = \frac{E}{C}$. The law is undoubtedly true, and not only is it true for the whole circuit, but it is true for any portion of the circuit considered separately, and I think that it is the overlooking of this fact which causes the first difficulty in understanding the law. The next difficulty arises from the false conception that the E.M.F. remains constant throughout the external circuit. It does nothing of the kind: it falls gradually between all parts of such external circuit in the direct ratio which the resistance of such part bears to the whole resistance of the circuit. Let us examine the two terms of our equation which we are capable of understanding—viz., C and R—and we shall find that the third term E, which we are incapable of understanding, is a variable term. First, as to C, without reference to Ohm's law, very little reflection will show that the current passing through the circuit must be the same at all points of the circuit; otherwise, as "Quivis" puts it, there would be a heaping up of the current somewhere. C is, therefore, constant throughout the circuit. Second, as to R, the resistance of the whole circuit must be the aggregate of the resistances of the various parts—suppose we consider the flow of the current in a portion of the circuit whose resistance is r_1 (obviously a fraction of the total resistance R), and let us call the remaining resistance of the circuit r_2. Then, since Ohm's law is true for any portion of the circuit considered separately, the relation of the current in the portion of the circuit whose resistance is r_1 may be expressed by the formula $C_1 = \frac{e_1}{r_1}$ and for the portion whose resistance is r_2 by $c_2 = \frac{e_2}{r_2}$. But since the current is constant throughout the circuit, C, c_1, and c_2 are all equal, and therefore $\frac{E}{R} = \frac{e_1}{r_1} = \frac{e_2}{r_2}$. Whence we see that, since r_1 and r_2 are only fractions of R, e_1 and e_2 must be only fractions of E, and also that the E.M.F. in the portion of a circuit whose resistance is r_1 (or, more properly, the fall of potential along that portion of the circuit whose resistance is r_1) bears the same proportion (or ratio) to the whole E.M.F. of the circuit as the resistance in such portion bears to the whole resistance of the circuit.

H. LATTEY.

[97053.]—**Carbon Paper.**—Lay the paper on a hot plate and rub with the following:—Mix 5oz. lard, 1oz. beeswax, ½oz. Canada balsam. Melt

together, then stir in lampblack till as thick as good crut; mix well while hot, and run into mould till cool. CARBON.

[97055.]—**Californian Grape Growing.**—Think statistics are few and far between. If you cared to ask Methuen and Co., Essex-street, W.C., or Stanford and Co., Cockspur-street, S.W., both London; they are very general publishers; they may have something on their list. "Tropical Agriculture," by P. L. Simmonds, of Spon, London, W.C., 1887, has about a page *re* California. Gives the produce of one acre at 12,000lb. of grapes, worth 5 cents per pound—Mission, white Muscat, Tokay Blassein rose, Peruvian, and black Morocco kinds. The yield, 1872, was 4,000,000gal., in 1873 was 3,800,000gal., besides 176,000gal. of brandy. In 1874 was 7,000,000gal., besides quantity required for distillation of 200,000gal. of brandy, or about 1,000,000gal. of must. In 1875 was 8,000,000gal. Mr. R. Chalmers, of Coloma, has planted on 110 acres 110,000 bearing vines, over 40 varieties of grape. He makes six to ten tons of raisins yearly. It takes 3 tons of grapes to make 1 ton of raisins. Raisin crop estimated for 1876 at 60,000 packages. White Muscat take the lead; sell at 10 cents a pound; Malagas worth 8 cents, &c. "Irrigation," by H. Stavant (O. Judd and Co., New York, 1892), mentions of an experienced vineyardist of Avignon as submitting his vines in winter mild and free from severe frosts to a lengthened irrigation of 30 days, during which a depth of 4in. of water was constantly maintained; in vineyard operation found to considerably diminish the injurious effects of the phylloxera and to greatly improve condition of vines. In Southern California vineyards are copiously irrigated four times only—at starting of first growth, at blossoming, at setting of fruit, and when fruit begins to colour. REGENT'S PARK.

[97060.]—**Alpha Orionis.**—Betelgeuse is certainly variable to the extent of about half a magnitude. I have frequently seen it about equal to Aldebaran; but it is at present, as "G. J." says, distinctly brighter than that star. It is given as variable from 1 to 1·4 in Chandler's Third Catalogue of Variable Stars; but to me the variation is more like 0·5 to 1·0. It has no regular period. J. E. GORE.

[97064.]—**Mitre Blocks.**—Perhaps Stanley's little combination "odd jobs" tool would meet querist's requirements if a mitre box is too expensive. J. D.

[97084.]—**Imitation Gold and Silver Paint.**—Generally made of powdered alloy bronzes, mixed with some kind of spirit varnish. Gold: Platina 7, copper 16, zinc 1. Silver.—German silver: Nickel 20, zinc 20, copper 60, lead 3. Imitation silver: Metallic arsenic 1, copper 9. Or tin ½oz., copper 1lb. Or zinc 1, tin 5, copper 4, lead 1, &c. REGENT'S PARK.

[97089.]—**Pneumatic Covers.**—Hold the inside of the cover in the steam of a boiling kettle till it comes away with a gentle pulling, slowly turning the cover round as it strips. I have stripped several this way, without injuring the canvas. Thoroughly dry canvas before putting new rubber on. REX.

[97095.]—**Photographic Enlarging.**—"H. H. S." will find a full description of a cheap home-made enlarging lantern or box, which was written by myself, and published in the "E. M." of March 24, 1899, p. 135, with diagrams of the same. PHOTO.

[97095.]—**Photographic Enlarging.**—If the enlargements are not of considerable size, the burning of some inches of magnesium ribbon in front of the negative will answer. J. D.

[97095.]—**Photographic Enlarging.**—What you require is a condenser, such as is used in all magic-lanterns. One that will cover most of a ½-plate can be obtained for about 5s. (Spiers and Pond, Benetfink, &c). This is placed close up to the negative, and any light almost, incandescent gas for preference, will serve for illuminating the negative.

Earlsfield, S.W. SILVERPLUME.

[97096.]—**Amyl Acetate.**—Not in water, but is so in alcohol, or spirit, ether, and fusel oil, known as pear essence. Copal soluble in rectified spirits of turpentine and in boiling alcohol; but, as a rule, insoluble in spirit, sparingly soluble in absolute alcohol. REGENT'S PARK.

[97096.]—**Amyl Acetate.**—This is practically insoluble in water. It is very volatile, and boils at 125°. In commerce it is known as "Jargonelle pear essence." It is used for flavouring sweetstuff, and for dissolving different resins; also largely in the preparation of celluloid varnishes, celluloid being freely soluble in amyl acetate.

S. BOTTONE.

[97097.]—**To Sensitise Bromide Paper.**—It will probably save querist both trouble and expense if he invests in one of the photographic manuals which gives the details, for the process is a lengthy one, which requires great care to carry through successfully. He will find a chapter on it in Burton's shilling "Modern Photography," or in special works by Abney and others. He will probably find his output will not compete with the bromide paper purchasable ready made, either in price or quality; but the experience gained will be valuable. J. D.

[97097.]—**To Sensitise Bromide Paper.**—Perhaps the process of converting ordinary P.O.P. into a bromide paper, as given by C. G. Polson in the *Amateur Photographer* of Jan. 27, 1899, may suit the querist. The process may be briefly described thus:—Ordinary P.O.P. is immersed for five or ten minutes in ferric bromide solution, taken out, washed, and dried, all operations being carried out in ruby or yellow light. A good formula for producing a slow bromide paper is as follows:—Ammonium bromide 4 drachms, sulphate of copper 30 grains, water 4oz. This paper can be worked in ordinary gaslight, being a chloro-bromide emulsion. An extremely sensitive bromide paper can be produced by simply immersing the P.O.P. in an ordinary 10 per cent. solution bromide of ammonium for five or ten minutes or more, being more sensitive the longer the bromide bath acts in certain limits. This is the gist of the whole article as contained in the *A.P.*, which I trust will be of service to the querist. IVANHOE.

[97100.]—**Lyddite.**—Picric acid mixed with collodion cotton, dissolved in ether, and formed into cartridges; made in France, called crelinite. Experiments made elsewhere, and found that the best way to detonate molten picric acid was the use of either very strong detonars or primer of dry guncotton. Picric acid was melted at a carefully-regulated temperature in a vessel in oil bath. Used for filling shells, and cast direct from melting-pot into projectiles. After it had cooled, the guncotton primer inserted, called in France as before, and in England lyddite (from the experiments being made at, or near, Lydd, in Kent). REGENT'S PARK.

[97102.]—**Speed Gears.**—I am thinking of putting gear on the market, so regret I cannot oblige you at present with sketch. That a two-speed gear is necessary and of great advantage is shown by results of big race in France last week for cycles without pedals, in which two classes competed, those with extra large and powerful motors, and others with two-speed gears, and all riders with latter were within time limit, and made better average performance, though ridden by inferior men, to higher-powered motors. I advocated use of speed-gears in this paper several times some numbers back, and was glad to see at late shows the matter is at last receiving the attention it deserves. By all means, use magneto-ignition in preference to batteries. Simms's appears to be only one ready for sale. It costs £6, and will outlast the tricycle. Plenty of other makers are experimenting with some form of magnets, but are not ready to supply; it is not a new idea by any means. Perhaps Mr. Bottone will give us definite information as to when his will be ready. MONTY.

[97103.]—**Kitchen Boiler.**—"Kitchen Boiler Connections," D. Williams and Co., New York, gives thus:—Remedy for noisy boilers: In visiting, been much struck by number of cases (owing to improper setting, under-size of water back, &c.) in which boilers rattle and rumble. The number of cases where pipes connecting water-back and boiler are sagged or run so as to form traps is very great, and size of pipes often very small. Wants to know what objection to setting boiler above water-back. In that way there can be easy incline for both pipes. Again, what is gained by making the circulating pipe so small? What harm in using 2in. or 2½in. pipe? It will reduce friction in pipes, and ought to give better results in heating water. Extra cost for larger size of such short length would not be very great, and customers would no doubt gladly pay difference if assured of a better supply of hot water and assist to reduce noise, &c. Then as to crackling in range boiler. The noises probably arise from defective circulation either from deposit in back or trap in pipes between range and boiler. Removal of the impediment or rearrangement of pipes giving freer circulation. If trouble is due to boiling of water, it can be stopped for a time by drawing off some of the hot water and letting boiler fill up with cold. A permanent remedy sometimes effected by placing firebrick in front of water-back and thus reducing area of heating surface. Where there is a strong water pressure, oftentimes on closing water faucet quickly, jar is transmitted to fixtures with such force as to cause trembling and rattling. Also due to the generation of steam where pressure of water to supply boiler is very light, which allows steam to accumulate at top of boiler in water-back and in circulating pipe. Immediately on opening of hot-water faucet, cold water rushes into boiler, steam at top of boiler at once cooled and condensed, leaving vacuum which is filled by rush of cold water, and where water meets result is very similar to bringing a hammer down upon an anvil with same force. Condensation and vacuum may be formed in return pipe from water-back, or in water-back, by steam coming in contact with cold part of pipe or cold water entering water-back, and much more.

REGENT'S PARK.

[97103.]—**Kitchen Boiler.**—If apparatus has been recently fitted, the trouble arises from imperfect arrangement, as the water does not circulate properly. Either of the following defects may be the cause. (1) A dip in either of the pipes; (2) The "flow" pipe projecting into the boiler or not standing high enough up into the tank or cylinder; (3) The cold water supply being connected to the "flow" instead of the return pipe. If the apparatus has previously given satisfaction, the present trouble arises from the pipes becoming stopped with fur, most likely at the boiler.

161, Albion-road, N. A. CLARKE.

[97104.]—**Eight - Plate Wimshurst.**—"K. M. C." will find that 20 sectors, each 4½in. length, ⅝in. broad at one end, and ¼in. broad at the other end, will give the best all-round results. The end of the sectors should be about ½in. from the edge of the plates. The combs should extend to about the inner end of their sectors; their points should be closely spaced. J. W.

[97105.]—**Bran Tea.**—Infuse in hot water, and sweeten to flavour. REGENT'S PARK.

[97106.]—**Induction Coil.**—To MR. BOTTONE.—No alteration would be needed beyond still greater care in the insulation, especially as regards the tube that separates the primary from the secondary, and the change of the gauge of the wire wound on the secondary, from No. 35 to No. 38 silk-covered wire. S. BOTTONE.

[97107.]—**Steam.**—(1) If there were no leakage, the quantity of water would not diminish. (2) Part, or all, of the oxygen of the steam would combine with the red-hot iron, and the hydrogen would remain in place of the original water.

W. J. G. FORMAN.

[97108.]—**Cold Glue.**—Liquid glue: Soft water, 1 quart; best pale glue, 2lb. Dissolve in a covered vessel by the heat of a water bath, cool, and add gradually of nitric acid (sp.gr. 1·335) 7oz. When cold, put into bottles. Very strong, and does not gelatinise. REGENT'S PARK.

[97109.]—**Dynamo.**—The amount of iron in the armature should be such as will conveniently hold the wire required to produce the desired voltage and current at the given speed; and the amount of iron in the F.M.'s and pole-pieces, irrespective of the yoke, should weigh at least seven times that of the armature. S. BOTTONE.

[97109.]—**Dynamo.**—Modern practice dictates that the flux density in the armature core shall not exceed 125,000 lines per square inch. For cast-iron 70,000 lines per square inch only is admissible, and note that in the fields the total flux is composed of the useful flux multiplied by the leakage coefficient for that particular type of machine. The above figures are the highest to which it is advisable to go. Personally, I find it (where weight is not a consideration) preferable to work at a lower flux density, and put more iron into the magnetic circuit, thus reducing enormously the amount of copper required in the magnetising coils. So few people realise that cast-iron is cheaper than copper.

A. H. AVERY, A.Inst.E.E.

Fulmen Works, Tunbridge Wells.

[97109.]—**Dynamo.**—A somewhat intricate series of calculations are required relating to the number of magnetic lines required and the reluctance of the complete magnetic circuit. Such books as "Dynamo-Electric Machinery" by J. P. Thomson, or "Dynamo Construction" by Urquhart, will give the required information.

W. J. G. FORMAN.

[97110.]—**Dynamo.**—A drum armature 3½in. long by 1½in. diameter, wound with about ¼lb. No. 20, running in a tunnel of suitable size, as mentioned by you, the field-magnets being shunt-wound with about 2¼lb. No. 22 d.c.c., might reasonably be expected to give 2 to 3 ampères, at about 15 volts pressure, if driven at 2,500 to 2,800 revs. per minute. It would be well under control of a ¼H.P. engine. S. BOTTONE.

[97110.]—**Dynamo.**—Armature wound with 8oz. No. 22, fields with 7lb. No. 20, connected in shunt; speed 2,500 revs. per minute; output 30 volts 3 ampères; ¼H.P. will be ample power to drive it. A. H. AVERY, A.Inst.E.E.

Fulmen Works, Tunbridge Wells.

[97111.]—**Norton's Door Springs.**—Why not use rising (viz., self-closing) butt hinges?

161, Albion-road, N. A. CLARKE.

[97114.]—**Telephone.**—If there were no objections otherwise, a single-line wire could be used, any individual station being called up by the number of times the bell is rung. Such a method would, of course, also allow of any one station communicating with any other, but would admit of no private conversation. If such a method be not admissible, then a separate line-wire must be run to each station, a switch provided at the home station,

and a means of ascertaining which station is ringing up. The cost would be about £16 to £18 for the instruments, exclusive of line-wire and cost of laying, &c. If "E. H. B." cares to write to me, I will let him have diagrams of connections, &c.

Moffat. W. J. G. FORMAN, C.E.

[97115.]—**Dynamo Construction.**—The proposed winding is quite disproportionate to the output and size of machine. To begin with, unless the bare iron of the armature were kept very small, which would be bad, it would be practically impossible to get 250 yards = 35½lb. of No. 11 on it. Besides, you do not want to use No. 11 at all to carry 22 ampères. Such a wire on a ring armature will carry 50 ampères easily. Use about 12lb. No. 14 (about 200 yards) on the armature, and 100lb. No. 18 (50lb. on each limb) for shunt-winding the field-magnets. This will give you a serviceable machine. S. BOTTONE.

[97115.]—**Dynamo Construction.**—This machine, as it stands, should give very good results. But there appears to be an enormous amount of copper on the fields—over 250lb.! With one of my Lahmeyer dynamos I get the same results with but 36lb. of copper in the field windings.

A. H. AVERY, A.Inst.E.E.

Fulmen Works, Tunbridge Wells.

[97117.]—**Medical Electricity.**—Better to have no Leyden jars; but, having them, the next thing is to see that they are not connected to the combs, or that their outside coatings are not connected together. And failing these, then keep the terminal balls close together; but this latter system is not safe because they may get shaken asunder. Use guttapercha-covered wire for the leads, and yourself try that the sparks are not too powerful. There is no danger to life, supposing the Leyden jars are not large. J. W.

[97117.] — **Medical Electricity.** — To MR BOTTONE.—If you keep the spark gap balls at a distance of ⅛in. from each other, you need be under no apprehension of giving or taking an injurious shock. No wet strings, &c., are required. If ⅛in. gives too weak a discharge, increase the spark gap till the desired intensity is obtained; and before going any further read carefully Dr. Monell's splendid work on "Electro-therapeutics," and there you will learn how he used an eight pair of 32in. plates machine.

S. BOTTONE.

[97118.]—**Cylinder for Oil-Engine.**— This you appear to want for stationary engine—should say, 4½in. dia. of cylinder by 5in. stroke, run 450 to 500 revs. per min. Do not exceed this speed with flywheels size you mention, as you would be getting near safe limit of circumferential velocity which may be taken at 80ft. per second for cast iron. Don't let engine race, and, to avoid accidents, use a good governor. Your flywheels appear heavier than necessary, as they would weigh about 2cwt. each size you give. Shaft should be 1¾in. diameter at least for this size; but a good deal depended on method of construction, whether bent, built up, or carved out. The new 4H.P. French motor is practically a dead copy of the 1¾ Dion, with all sizes increased proportionately one-quarter size larger, cylinder being 3⅛in. diam. by 4in. stroke; but valves are very large, being about 1⅜in. diam. It has done over 40 miles per hour on the road a few weeks since, and has a curious device for cooling by holes through cylinder, which, I am told, is very effective, though I wait further particulars, as sketches sent to me are not clear, showing holes round bottom of cylinder when piston is at top of stroke. This is new to me, and I want to know where oil goes and dust. Longuemare carburator in general use with these engines. MONTY.

[97120.]—**Electric Light.**—To MR. BOTTONE.—Suppose you use a 10-volt lamp, you will need five chromic-acid cells, double-carbon, single-zinc type, about pint size. These will run the lamp for three hours with one charge. You will find a description of this type of battery, with the arrangement to make it portable, in my book "Electrical-Instrument Making"; or you may arrange to cover the cells (the zinc and carbon being previously lifted out) with a lid faced with indiarubber.

S. BOTTONE.

[97122.]—**Small Motor Winding.**—Rewind the fields with 4lb. of No. 18; or, if there is not room for that, with 1½lb. No. 20, and you will find a vast improvement. A. H. AVERY, A.Inst.E E.

Fulmen Works, Tunbridge Wells.

[97123.] — **Wireless Telegraphy.** — To MR BOTTONE.—Immediately on reception of the wave, the decoherer strikes the tubes and decoheres the filings. This must be so, because the cessation of the wave from the transmitter could not decohere. Hence the dash is really produced by a very rapid succession of small dots, which simulate a continuous dash. S. BOTTONE.

[97124.]—**Medical Coil.**—To MR. BOTTONE.—If you connect a 50-sheet condenser with tinfoils about 3in. by 5in. to the vibrating hammer and platinum contact pillar respectively of the coil, you will, with two bichromate cells, get from ¼in. to ⅜in. spark. The dials do not mark the strength; they simply show how far the sliding brass tube has been pulled out. A gut passes from the tube round a pulley fixed to the same axis as the pointer on the dial. At the other end of the gut is a weight or spring to pull it back again. As the tube is pulled off the core, so the index turns round on the dial; but this indicates no real current, since the index is pulled round just the same, whether the coil be connected to a battery or not. S. BOTTONE.

[97126.]—**Problem.**—From the given equation, we have—

$$x^{\frac14} = (x+1)^{\frac14} - (x-1)^{\frac14}.$$

Squaring both sides—

$$x^{\frac12} = (x+1)^{\frac12} + (x-1)^{\frac12} - 2(x^2-1)^{\frac14}$$

or— $$x^{\frac12} + 2(x^2-1)^{\frac14} = (x+1)^{\frac12} + (x-1)^{\frac12}.$$

Squaring both sides again—

$$x+4(x^2-1)^{\frac12}+4x^{\frac12}(x^2-1)^{\frac14} = x+1+x-1+2(x^2-1)^{\frac12}$$

or— $$4(x^2-1)^{\frac12}+4x^{\frac12}(x^2-1)^{\frac14}=x+2(x^2-1)^{\frac12}$$

or— $$2(x^2-1)^{\frac12}+4x^{\frac12}(x^2-1)^{\frac14}=x.$$

$$\therefore (x^2-1)^{\frac12}+2x^{\frac12}(x^2-1)^{\frac14}=\frac{x}{2}$$

Completing the square on the left-hand side of this quadratic, we have—

$$(x^2-1)^{\frac12}+2x^{\frac12}(x^2-1)^{\frac14}+x=\frac{x}{2}+x=\frac{3x}{2}$$

$$\therefore (x^2-1)^{\frac14}+x^{\frac12}=\pm x^{\frac12}\sqrt{\tfrac32}$$

or— $$(x^2-1)^{\frac14}=\pm x^{\frac12}(\sqrt{\tfrac32}\mp 1)$$

$$\therefore (x^2-1)^{\frac12}=(x^{\frac12})=x(\sqrt{\tfrac32}\mp 1)$$

and— $$x^2-1=x^2(\tfrac32+1\mp 2\sqrt{\tfrac32})^2$$

$$x^2-1=x^2(\tfrac52\mp 2\sqrt{\tfrac32})^2$$

or— $$x^2-1=x^2(\tfrac{25}{4}+\tfrac{12}{2}\mp 10\sqrt{\tfrac32})$$

$$x^2-1=x^2(\tfrac{49}{4}\mp 10\sqrt{\tfrac32})$$

$$\therefore x^2(1-\tfrac{49}{4}\pm 10\sqrt{\tfrac32})=1$$

or— $$x^2\left(\frac{\pm 40\sqrt{\tfrac32}-45}{4}\right)=1$$

$$\therefore x^2=\frac{4}{\pm(40\sqrt{\tfrac32}\mp 45)}$$

$$x^2=\frac{4}{\pm(\sqrt{2,400}\mp 45)}=\frac{4}{\pm(\sqrt{400\times 6}\mp 45)}$$

$$\therefore x=\pm\frac{2}{\sqrt{20\sqrt{6}\mp 45}}$$

J. E. GORE.

[97126.]—**Problem.**—Prof. Chrystal's result appears to me to be quite accurate, for if—

$$x^{\frac14}+(x-1)^{\frac14}=(x+1)^{\frac14}$$

$$\div x^{\frac14}\quad 1+\left(1-\frac1x\right)^{\frac14}=\left(1+\frac1x\right)^{\frac14}$$

Put— $1-\dfrac1x=y^4$ And, therefore, $x=\dfrac{1}{1-y^4}$

Then— $$1+y=(2-y^4)^{\frac14}$$

Raise to fourth power.

$$\therefore y^4+2y^3+3y^2+2y-\tfrac12=0.$$

Put— $y=z-\frac12$ Then— $z^4+\frac32z^2-\frac{15}{16}=0$

And— $$\therefore z^2=\tfrac14(-3\pm 2\sqrt6)$$

And— $$z=\pm\tfrac12(-3\pm 2\sqrt6)^{\frac12}$$

$$\therefore y=-\tfrac12[1\mp\sqrt{(-3\pm 2\sqrt6)}]$$

$$\therefore x=\frac{1}{1-y^4}=\frac{2}{\mp(1\mp\sqrt6)(-3\pm 2\sqrt6)^{\frac12}}$$

$$=\frac{2}{\sqrt{[(-3\pm 2\sqrt6)(7\mp 2\sqrt6)]}}$$

$$=\pm\frac{2}{\sqrt{20\sqrt6-45}};\ \pm\frac{2\sqrt{-1}}{\sqrt{20\sqrt6+45}}$$

West Norwood. HENRY T. BURGESS.

[97127.]—**To Electricians.**—Though an accumulator would work with ordinary commercial sulphuric acid or oil of vitriol, it is advisable to use pure sulphuric acid (free from arsenic and other impurities), as otherwise the impurities will ultimately ruin the accumulators. It is false economy to use the cheaper acid. P. LANDACH.

[97127.]—**To Electricians.**—The acid used in accumulators is known as "brimstone sulphuric acid," and is quite distinct from either the pure acid or the commercial.

A. H. AVERY, A.Inst.E.E.

[97127.]—**To Electricians.**—The oil of vitriol used for accumulators is ordinary commercial—not pure. But you must specify brimstone oil of vitriol—not from pyrites, as this latter contains arsenic, &c., which is detrimental to accumulators.

S. BOTTONE.

[97128.]—**Rate of Interest.**—Presuming that the interest is payable half-yearly, the £1 10s. represents 4½ months' accrued interest, which will be repaid out of the first dividend of £2 receivable in 1½ month time. There will then remain £6 10s. of premium to be repaid in ten years, which, if spread equally over the ten years = 13s. per annum. The interest received, therefore, on £106 10s. will be £4 less 13s. = £3 7s., being at the rate of 3·15 per cent. But this is not quite a fair way of paying off the premium, and the problem is to find what rate per cent. will provide a sinking fund to pay off the £6 10s. gradually in ten years. This is a difficult problem to solve mathematically; but in the present case the rate is 3·23 per cent., as will be seen from the following table:—

Year.	Total Amount at Commencement of Year.	Annual Dividend.	Amount Required for Interest at 3·23 per cent.	Sinking Fund for Repayment of Premium.	Amount of Premium Remaining at End of the Year.
1	£106·50	£4	£3·44	£0·56	£5·94
2	105·94	4	3·42	·58	5·36
3	105·36	4	3·40	·60	4·76
4	104·76	4	3·38	·62	4·14
5	104·14	4	3·36	·64	3 50
6	103·50	4	3·34	·66	2 84
7	102·84	4	3 32	·68	2·16
8	102·16	4	3·30	·70	1·46
9	101·46	4	3·28	·72	0·74
10	100·74	4	3·26	·74	0 00

OMEGA.

[97128.]—**Rate of Interest.**—I think "Chercheur" will find the following method simple and accurate, though not scientific. As the price is 108, and £1 10s. of dividend has accrued, the true price paid is 106½. The return at this is $\frac{400}{106\frac12}$ = £3·75587 nearly. Then calculate the annuity, which in ten years will amount to £6 10s., and subtract it from the above. Of course, the rate of compound interest can be assumed—say at 3½ per cent, or at any other rate preferred, provided it is reasonably near the rate of interest on the stock. A. O. S.

[97128.]—**Rate of Interest.**—The actual cost of the security (after deduction of accrued interest) is £106 10s. Thirteen shillings per annum sinking fund must be put away to make up the £6 10s. premium in ten years. So the amount available as interest is £3 7s., which is, as nearly as possible, £3 2s. 11d. per cent. R. B.

[97129.]—**Wheeled Carriages.** — If, as you state, three-wheeled carriages are more stable than four, then a one-legged man should be better off than one with two. But it seems against common-sense and ordinary reasoning to expect such to be the case. The much-advertised three-wheeled American vehicle collapsed a few weeks back, through single front wheel not being so good as four, and being also carried in weak form of cycle-fork. Railway authorities say engines with high centre of gravity run much better than ones with it low, for which you can consult Mr. Stretton, who is an expert on such matters. For road purposes conditions are vastly different. Certainly, the longer wheel-base is productive of a steadier running vehicle, as it reduces vibration. The smaller wheels are more a matter of convenience, and are cheaper to make as regards tyres, &c. Rear-steering is objectionable, and renders carriage very unstable.

MONTY.

[97130.]—**Drawing Wire.**—According to Bucknall Smith on wire, the Hadfields of Sheffield have introduced carbon steel, containing 7 to 20 per cent. of manganese, giving tough, hard non-magnetic metal. REGENT'S PARK.

UNANSWERED QUERIES.

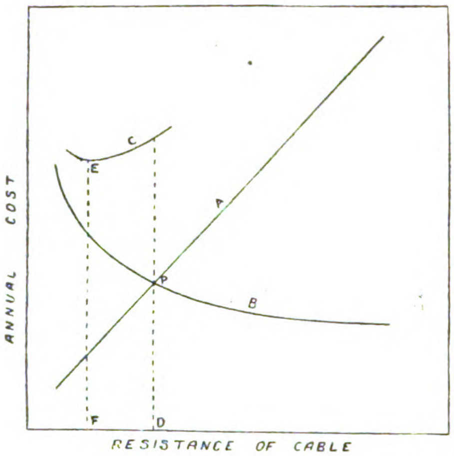
The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered, are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.

QUERIES.

[97131.]—**Metal Polish.**—Will some reader kindly inform me how to make metal polish for cleaning brass and silver-plated instruments?—A CONSTANT READER, Oldham.

[97132.]—**Dry Inhaler.**—I should be glad if one of "ours" could tell me how to replenish a menthol dry inhaler which has become exhausted, as it is very useful in helping to cure a cold? In the one I bought, a piece of blotting-paper was impregnated with menthol, which was contained in a glass tube, supported by springs in a metal case. If the menthol is to be dissolved, kindly state by what means.—SUTTON.

[97133.]—**Kelvin's Rule for Size of Feeders.**—"The size of the feeders must be such that the interest for one year on money lying idle in their cost and laying, together with depreciation, must be equal to the value of the energy wasted in them during one year." (Joyce's examples in *Electrical Engineering*.) In the diagram A is the "curve" of cost per annum of energy wasted in cables of different resistances. B is the curve of interest on cost of cable as laid. According to above



rule, the point P of intersection of these curves will give D, the most economical resistance of cable; but the total cost per annum of the feeder will be: interest, &c. + cost of waste energy—that is, the sum of the ordinates of A and B. The curve C is the sum of A and B, and the lowest point E on C should give the most economical resistance F—a much smaller resistance than D. What is the explanation of this?—ERG.

[97134.]—**Vox Humana.**—Please describe the method of making a vox humana, and fitting same into an American organ, containing four sets of reeds as follows:—Diapason, double diapason, celeste, and melodia.—C. J. PLATER.

[97135.]—**Expansion Rate of Metals.**—Please inform me, *re* the above, the expansion of aluminium compared to wrought or rolled iron, in length, for a given rise in temperature. I cannot find a table in my books with the information desired. Any hints respecting the first-named metal will be thankfully received?—G. W. GRANGER.

[97136.]—**Multiple-Plate Wimshurst.**—I am about making a Wimshurst, chiefly for X-ray work, and I would feel greatly obliged if Mr. Wimshurst would kindly advise as to the following points—viz.: (1) Would a machine made with eight 36in. glass plates be much better than one made with twelve 28in. glass plates? Which machine would he recommend? (2) What should be the thickness of glass for (*a*) 36in. plates, and (*b*) for 28in. plates? (3) What sort of condensers would he recommend? (4) What distance should front and back plates be from the trunnions?—T. M. C.

[97137.]—**Grammaphone.**—Would Mr. Bennett be so good as to state number of teeth in the various pinions and wheels of motor of grammaphone so fully described by him in the last volume?—T. M. C.

[97138.]—**Polishing Specula.**—I have spent very many hours trying to polish an 8in. specula with a paper polisher on glass tool, but cannot get a good polish. The surface seems granular under magnifying glass, and does not seem to progress beyond a certain stage. In polishing metal, glass, &c., a rapid motion of the polisher, instead of the slow movement, seems necessary. Any hints from workers will oblige. Is pitch and rouge quicker and better than paper and putty-powder?—ASTOR.

[97139.]—**Rearing and Keeping Goats.**—Can any of "ours" give reliable information as to above (for milking), such as best breeds, and when to breed to obtain strong kids, best kinds of food, when goats have to be kept penned in, and list of foods that are not suitable or poisonous, age at which milking should begin, how to tell age, &c.? I am living in a country village, and would be glad to hear of any book (cheap) on above subject, with names of publishers (if Editor will not object), as any such information in this neighbourhood is extremely difficult to obtain. I have been told there is a Goat Society which will supply responsible cottagers with goats, but cannot obtain name or address, or whether they publish any work on the subject or not.—HENRY SALTER, Wroughton, Wilts.

[97140.]—**Dynamo.**—I have a horizontal engine of 1/8N.H.P. working at 40lb. steam pressure. Could any reader advise me as to what pattern and size dynamo could be satisfactorily run by it? Any hits most acceptable.—DYNAMO.

[97141.]—**Glass Blowing.**—I have tried often to join bits of barometer tubes, and have cooled the joints in cotton wool slowly, but almost invariably they have broken or snapped across at the joining, sometimes even before they have been removed from the wool. Perhaps some of your practical readers would kindly lend a helping hand. I have "Shenston." Is there any better work on the subject?—A. R.

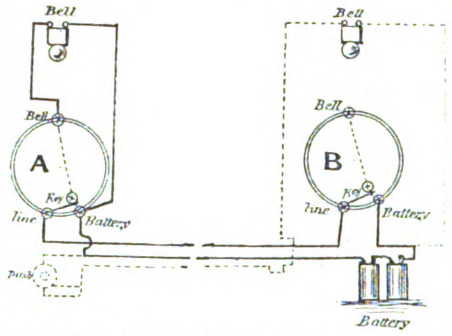
[97142.]—**Telescope.**—(1) Can anyone suggest a crucial test as to whether the lenses in my home-made 2in. simple telescope are correctly mounted—that is to say, whether they are square with axis of tube, and whether their centres are in a straight line? (2) Can anyone suggest a method of erecting an inexpensive home-made stand for above? The length of telescope is 48in.—ALGOL.

[97143.]—**Induction Coil.**—Will Mr. Bottone kindly tell me the lengths of No. 42 s.c. platinoid wire for a switch with 16 contacts to act as a resistance in primary circuit of shocking coil? The coil to give a very weak shock on first contact, and full power on last. Size of coil:—Core, 5/16 diam., 4in. long; primary, No. 22 d.c.c., 4 layers, 57 turns each layer; ¾in. total diam. of primary; secondary, 3½oz. No. 36 s.s.c., wound on cardoard bobbin to slip over primary. I presume the contact-breaker would have to be very delicate to work with one bichromate cell. A water resistance does not work in secondary circuit. Will he also say if it is possible to make a coil with No. 42 d.s.c. wire, if well insulated? Also, what is cause of water resistance not acting when put in circuit with secondary of a coil to act as shock regulator?—J. B. BANK.

[97144.]—**Acetylene Cycle Lamp.**—I find a great trouble to keep the water-valve of this lamp tight. Although screwed down, the water still leaks through. Could any of your readers tell me how to remedy this? The valve-rod goes down through the water chamber, and the seat is at the bottom.—C. A. P.

[97145.]—**Ampmeter.**—Could any reader tell me how to make a simple ampmeter for a 10-volt 4-amp. dynamo?—PERPLEXED.

[97146.]—**Stanley Telephones.**—If Stanley telephones are similarly joined up, I get a continuous current on the bell circuit. So to avoid this I am running a third wire (which is shown by dots on the drawing) with a push at A end to operate the call-bell at B end. Am I right in



so doing? The line and bell terminals are joined when the receiver rest in the grooves provided for it on the transmitter.—PERPLEXED.

[97147.]—**Britain v. United States.**—Can Mr. Editor or any reader of the "E.M." tell me which country, Great Britain or United States, owns the most people worth 1,000,000dol., or, say, £250,000?—A READER.

[97148.]—**Isle of Man Steamers.**—Can any of "ours" supply me with particulars of the paddle-steamer *Ben-my-Chree* — particularly date she was built?—J. M. S. P.

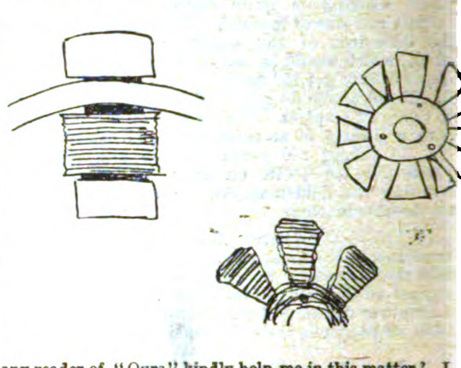
[97149.]—**Manchester Dynamo.**—To MR. BOTTONE.—I have made a Manchester dynamo, supposed to be 55 volts 8 ampères, from instruction in Vol. LXIV., commencing at No. 1659, but cannot get machine to excite when the fields are connected in series. I have connected the fields in parallel, but only get enough to light two 16-candle 30-volt lamps. Having 60 yards of active wire on armature, I ought to get 60 volts. The armature is a laminated drum, with 36 pins to divide coils, and wound with 18 coils four wires deep, making 30 conductors in each coil, making 540 conductors altogether = 60 yards active wire; armature core 4in. long, 4⅜in. diameter (finished 5⅛in.); armature wound with 5lb. No. 17 S.W.G. The field-magnet cores are 5½in. long, 2⅝in. diameter, wound with 11lb. No. 20 5½in. on each core; the cores are ordinary bar-iron. The pole-pieces are of soft cast-iron, 15in. long, 4in. wide, 2in. thick; tunnel bored out to 5¼in.; fields connected shunt, comutator 18 parts, speed 1,800. Any information will greatly oblige.—TRY AGAIN.

[97150.]—**Wireless Telephony.**—Can Mr. Bottone or some other electrician oblige with information about this subject over and above wireless telegraphy, which is understood? The distance that it is wished to use the telephones over is only seventy yards.—TELEPHONES, Birmingham.

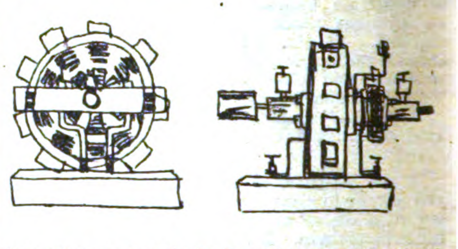
[97151.]—**Oil Engines, &c.**—Could any of our readers oblige me with the following? (1) What size and kind of foundation is required for a ¾B.H.P. oil-engine? (2) Would a piece of York stone 2ft. 3in. by 18ft. 6in. be suitable for a 50-volt 4-amp. dynamo-bed? (3) Having a 1in. leather belt, is that strong enough to drive dynamo? If not, what size should I require?—PERPLEXED.

[97152.]—**Coherer.**—I am about to construct a couple of coherers, using glass tube about ⅛in. bore. Should the terminal wires fit the tube so that the filings are only in the small space between the ends? What should this space be? I purpose using nickel filings and German silver terminal wires. Will this be correct? I purpose using a 6in. spark-coil. Should the contact-breaker be removed, and a key or switch substituted? Can I purchase a book with fairly full particulars? Distance required to signal about one mile.—COHERER.

[97153.]—**Building an Alternator.**—In the October 1st, 1897, number of the ENGLISH MECHANIC appeared an article on building a small alternator. I have started to build one on something the same principle, only a large one, for lighting purposes. I want the machine to give a high-tension current single-phase for supplying transformers in parallel at some distance, the current being carried on overhead bare conductors. I should excite field-magnets off 100-volt mains. Would



any reader of "Ours" kindly help me in this matter? I am in charge of a private continuous-current electric-light plant, and I wish to build this machine in my spare time, only, of course, it must be cheap, or I cannot do it. The parts I have already got are: one soft iron ring, 4in. wide ⅜in. thick, internal diameter 20in.; nine soft iron bolts 7in. from face of head to end of screw, head and nut 2⅝in. by 2in.; one soft iron bolt same dimensions, only 1in. longer, to go through bed-plate; twenty brass discs to form field-winding bobbins to slip over bolts; four steel bolts 11in. long, to bolt frames to ring; two brass rods, 2in. diam. 5in. long, ⅜in. hole for bearings, to be brazed on to frames; one brass rod 2in. diam. 3in. long for armature hub, also bored with ⅞in. hole for shaft; two oil-cups; one steel shaft ⅞in. diameter; four brass plates for side frames, 24in. long 4in. wide by ⅛in. thick; two iron washers for holding armature plates together. I give sketch of arrangement. In the first



place, what more parts do I want to complete the job beside thin iron plates to make armature, laminated with paper? What wire should I use for poles and armature, and how many turns, &c., and what voltage is best—say 1,000—how would that do? Of course, I want the output to be as big as possible. What resistance should I insert between 100-volt mains and pole winding? I should be glad of any information enabling me to do this job, as I don't know much about the theoretical part and the calculations; simple explanation would be most acceptable. It must be high-tension, as the current will have to go some way to its work. Please say what is about right, taking into consideration expense of insulation on armature windings.—LIGHTNING.

[97154.]—**Bone Bearings.**—Will "Jack of All Trades" kindly answer the following with regard to his letter on bone bearings? (1) Do you run bone bearings without oil, or do you feed them with oil as in ordinary bearings? (2) What animal supplies the best bones for bearings—boiled, or baked, or raw? (3) How do bone bearings act in damp places, as for turbine bearings, &c., and what effect has water on them? (4) Up to what pressure per square inch is it advisable to run bearings? (5) Would they do for spindles running at 4,000 to 5,000 revolutions per minute? (6) How do they run when in a high temperature, as per gas-engine? (7) Are they suitable for oil-engines of about ½ to ¼ B.H.P. for connecting-rod, main bearings, &c.? Also small steam-engines, launches? I notice you say they are "everlasting and clean." What is the cause of them being everlasting, that most desirable quality? I suppose bone bearings being porous, its surface gets worn down, filling up the pores, and also rubs some off the revolving shaft, thus forming a smooth and well-fitting journal. (8) Is bone self-lubricating? (9) What is the best method of burnishing bone, and with what powder? Also what tool-angle is the best for turning bone?—O. G. A. P.

[97155.]—**Catch Question.**—Can any reader explain *why* 30 articles at 3 for a penny, plus 30 at 2 for a penny, are not equal to 60 at 5 for twopence?—DAMON.

[97156.]—**Stereoscope.**—I shall be greatly obliged if anyone can give me the description of a stereoscope of the reflecting form to look at large stereoscopic pictures? I have seen radiographic stereoscopic pictures of bones. How is it possible to obtain them?—F. M.

[97157.]—**Silver-Plating Aluminium.**—Forks and spoons of aluminium are very light, and very nicely made and cheap. Can these be electro-silver-plated with advantage?—ELECTRO.

[97158.]—**Bichloride of Mercury Disinfectant.**—I have a Staffordshire earthenware w.c., white hopper and trap, the base of whose glaze is copper. The trap is connected by a soldered joint to a length of about 3ft. of lead pipe, which connects with a thin cast-iron soil-pipe. I am desirous of using bichloride of mercury as a disinfectant in the glazed trap, so diluted that it will, when mixed with the water in the trap, be in proportion of one part to one thousand parts of water. Will this by long-continued use have any injurious effect on the glazed

earthenware trap, the solder joint, the lead out-go pipe, or the thin cast-iron socket soil-pipe? Be it noted that it will remain in the trap for considerable spaces of time without disturbance, but will only pass through the lead and iron pipes.—R. P. W.

[97159.]—**Piano Strings.**—Can any reader give me any information as to making a simple machine to make pianoforte covered strings?—TUNER.

[97160.]—**Automatic American Organ.**—Any information as to the construction of automatic playing American organs, particularly the description of motor used to wind the perforated music will be appreciated.—TUNER.

[97161.]—**Ship's Surveyor.**—Please give me any information as regards the exam. for ship's surveyor, Board of Trade—such as amount of knowledge required, what books best to study, where these are obtainable, or such other information as experience suggests.—B. J. J.

[97162.]—**Dynamo as Motor.**—Having tried to run an Elwell-Parker dynamo (designed for 25 amps 300 volts) as a motor, from 100-volt circuit, I find that, although taking 35 amps, it produces no power to speak of. All connections appear to be perfect, and machine runs well as a dynamo at its proper load. Can any electrical reader kindly explain the reason of this?—SENBAR.

[97163.]—**Aluminium Gas-Engine.**—Could any reader inform me if it is possible to construct a satisfactory aluminium launch engine to be driven by compressed gas? What would be the probable weight of 5H.P. and 10H.P. engines, and boilers of same H.P., in weight?—W. M.

[97164.]—**Zinc Connection.**—What is the best method of making connection with zincs, the bulk of the connection being below the surface of the solution. Soldering, I find, does not hold to amalgamated zinc, and, if riveted, would not a galvanic action be set up between the zinc and copper or iron rivet? I know a mercury connection is best, but it is not possible to use it in my case.—FARADAY.

[97165.]—**Drill Makeshift.**—I have a variety of braces and drills, and a vice securely fixed to a carpenter's bench, but find it very great labour to drill small holes in thick zinc plates, &c., with the ordinary brace and a drill. Can anyone suggest an arrangement where a greater pressure can be produced with the same guiding power? I tried an overhead lever, having a loop to put the foot in to bear down on the drill, but the drill "wobbled" fearfully, making a wretched-shaped hole.—IMPATIENT.

[97166.]—**Chromic Battery Without Acid.**—From my small knowledge of this acid, I conclude sulphuric acid is used in its preparation; therefore, would it do to use in a double-cell merely mixed with water, and dilute acid with the zinc as usual? If so, what proportion should the water bear to the powder? I want to use these batteries in lieu of Leclanchés, but the zinc consumes away so in a Fuller through the strong chromic acid working through the porous cells.—SUBSCRIBER FROM VOL. II.

[97167.]—**Backstay for use with Traversing Mandrel.**—Will Mr. Evans or some other reader help me in a difficulty? I have fitted to my lathe, which has a traversing mandrel, a backstay to take the thrust when boring, similar to that recommended by Mr. Evans on p. 455, Vol. LVIII of "E.M.," so that the screw in the stay bears against the head of the screw in the end of the mandrel; but I find that the result is to tighten the screw in the end of the mandrel until the mandrel becomes locked. How is this to be avoided?—E. L. H.

[97168.]—**Flare Spots.**—I have two lenses which have flare spots, and sometimes cause dense spots on negatives. Can anything be done to improve the lenses?—OPTICAL J.

[97169.]—**Oil-Engine for Launch.**—Would "Oil," "Monty," or any other of your numerous correspondents be so kind as to supply me with a sketch and few particulars of a simple tube-ignition oil-engine for launch?—one to use paraffin preferred.—O TOM OBILE.

[97170.]—**Grammaphone Records.**—Can anyone tell me how these are made?—I mean the black celluloid ones such as are used in the streets.—FRED. DAVIS.

[97171.]—**Stone.**—By what chemical tests can it be ascertained if stones contain lime?—CHEMICAL.

[97172.]—**Holtz Machine.**—To MR. BOTTONE.—Would you kindly say what length spark the Holtz machine, described in your book "Electrical Instrument-Making," would be likely to give if well-made? Are these machines difficult to excite? Could they be excited by a Wimshurst? If so, please give directions. Would such a machine be of practical use for X rays? If not, would you kindly give modifications or directions of one of this type that would be?—HOLTZ.

[97173.]—**Pigeon-Post Photographs.**—I shall feel obliged if any of your correspondents can give me any information as to the detail process of making these microscopic photographs? The ordinary collodion process does not yield a satisfactory result.—S. J.

[97174.]—**Water Power.**—I should be glad if some of your correspondents who have experience would inform me what power I should be likely to get from a water supply delivered through a 6in. pipe and having a fall of 4ft? Also, what size of turbine and dynamo would give the best results? I want to fit a few electric lights in my house by this means, if possible.—J. S. S.

[97175.]—**Watch Repairs.**—Can any reader give me sketches of a rocking-bar and shifting-sleeve keyless works, with full particulars how to examine same?—G. S.

[97176.]—**Cement for Vulcanite.**—Can some reader kindly tell me of a cement for vulcanite? I do not want it so much for fastening pieces of vulcanite together, as they will be screwed, but for making joints that are impervious to water and acids.—W. N.

[97177.]—**Cold Feet.**—Would any reader kindly give me a remedy for cold feet? Have tried heating compresses, and cold water bathing followed by brisk rubbing, without benefit.—IRON TURNER.

[97178.]—**Joint and Piston Packing.**—Kindly tell me how to make a joint such as the one on the cylinder end, and how to pack piston-rods of portable engines?—E. J. P.

[97179.]—**Lyddite Shells.**—Can any of "ours" tell me the construction of the explosive cap which is placed between the clapper-stick used in pantomime, and when the stick strikes that part of the anatomy which will do the most good? There is a loud explosion.—SONHUD DIE.

[97180.]—**Marine Navigation.**—Will any reader kindly explain the following? I don't mention the "line" or the paper, but it is stated that a well-known Transatlantic liner can steam at four knots with the main throttle shut, by the use of the exhaust steam of the auxiliary engines only. About 30 tons per day is the necessary consumption for auxiliaries, and the exhaust steam is sufficient to propel the ships at four knots and keep the machinery ready for immediate increase of speed to 20 knots.—M. E. V.

[97181.]—**Giddiness.**—Will some reader recommend a remedy? I have been troubled with it three weeks. It is worse when moving about. Objects appear unsteady, and I am liable to fall if I turn aside briskly.—VERTIGO.

[97182.]—**Extra-Hardened Grammaphone Needles.**—I have a considerable number of extra-hardened needles from America. 1. I am told they injure the records; is this correct? 2. What is the best means of softening them? 3. For how many records should they be used as hard and as soft needles?—S. N.

[97183.]—**Painting on Silk or Satin.**—How is silk or satin prepared for painting upon with oil or water-colours for the production of such articles as fire-screens, &c.?—F. J. G.

[97184.]—**Portrait Painting in Water-Colours.**—I have hitherto confined myself to small views landscapes or sea-views, &c.—with which I have got on fairly, but I now wish to try a portrait, size about 10in. by 7in., in which the head would be about 3in. or less. I understand from a manual that for the shadows of the face madder brown and French ultra are used; also for the flesh tint (fair) Roman ochre and pink madder; and for finishing touches, madder brown, raw sienna, lake, &c. How are these tints laid on? Are they blended upon the paper (shadow and flesh tints) while wet? If so, it would appear that the whole face must be painted very rapidly. Or are they laid on separately, and softened off by some after-process? In this case, which would be put on first—the shadow or flesh tint? Also, as to the "finishing touches"—what is the method adopted? Is stippling used, or cross-hatching, or simply washes? A few hints on the proper procedure would be very acceptable.—F. J. G.

[97185.]—**Bookbinding.**—Could any reader tell me how to do up binding of a set of books?—half calf, dark brown leather, gloss for the most part rubbed off, exposing the rough leather through.—BOOKS.

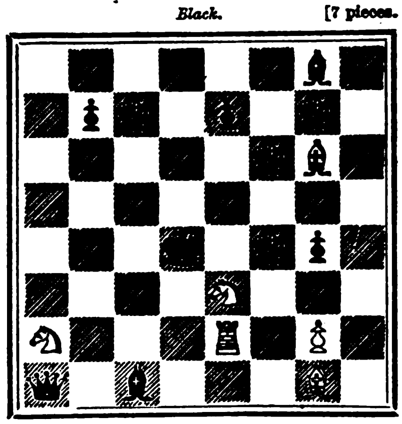
[97186.]—**Speculum.**—I have in my possession a 6in. metal Gregorian speculum, which I intend to bracket on to the side of my 4in. refractor and use without a tube. The length of my refractor is 5ft. 9in., and focus of speculum is the same, so that I shall have to get focus shortened, say, about a foot. I would like to know what "H." thinks of this arrangement. I have no small mirrors, but intend to match large speculum with ordinary glass concaves till I get one to suit, and then get a true glass concave made of the same focus as that which seems to perform best. In altering focus of large speculum, is there anything special to note about the required figure to give best results with simple concave small mirror? I may say I know very little practically of Gregorians, and any advice will be welcome.—GREGORIAN.

CHESS.

All communications for this column to be addressed to The CHESS EDITOR, at the Office, 332, Strand.

PROBLEM No. 1703.—By B. VALLE.

Black. [7 pieces.



White. [8 pieces.

White to play and mate in two moves.

(*Solutions should reach us not later than Dec. 11.*)

Solution of PROBLEM No. 1701.—By C. FARUFFINI.

Key-move, Kt-Q3.

NOTICES TO CORRESPONDENTS.

PROBLEM No. 1701.—Correct solution has been received from Frank Gowing, S. Woollen, Richard Inwards, A. Tupman, F. B. (Oldham), Alfred E. Oxley, Jas. Mason, Rev. Dr. Quilter ("Very clever"), J. E. Gore ("Pretty"), Quisco, T. Clarke.

H. B. F., P. H.—Only solution as above.

ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries, put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

*** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

The following are the initials, &c., of letters to hand up to Wednesday evening, Nov. 29, and unacknowledged elsewhere:—

M. GLOVER AND Co.—T. M. C.—Shaver.—W. J. Rogers. A. J. H.—F. J. Buxton.—Rotos.—Lux.—E. Jones.—D. J.—J. F. H.—Electro.—Voltage.—Fleur de Lys.—Jack of All Trades.

W. R. RICKMERS.—Really we do not see that your letter in the slightest degree adds to present information with regard to the subjects you deal with!

ARTHUR E. GILBERT.—We have no objection to free discussion, but your style of arguments will not do! The letters were neither "puerile," nor do the writers "lack mechanical knowledge." We want facts, not flippancy.

JAMES PARIS.—We know nothing of the advertiser, and have never had any complaint against him. Pardon us for again saying we cannot interfere. In all cases of dispute as to quality or right description of goods, we should first have to satisfy ourselves, by inspection, that there was reasonable ground of complaint. You cannot seriously expect the editor of any newspaper to do this.

G. E. TURNER.—There have been many articles, &c., about model yachts in the back volumes; but a series of articles appeared in LXIV., commencing with No. 1639, the first in that volume. See pp. 1, 26, 49, 77, 101, 123 of Vol. LXIV.

J. GIBSON.—Any of our advertisers dealing in electrical apparatus would supply a suitable list with prices. Most of the firms who supply the apparatus also sell textbooks to match the sets of apparatus. But why not let the boy read up the subject in our pages, with the aid of the elementary work he has?

S. WHITAKER.—The paragraph on p. 337 is definite. The investigations to be carried out are for determining the possibility of ascertaining the "absolute zero of temperature." "Heat" and "temperature" are two different terms, as explained in the textbooks, and many times in back volumes. At present no one can answer your question.

LENA WALTERS.—In some of the textbooks there are glossaries, but we do not know of any special dictionary. The "Dictionary of Scientific Terms," by W. Rossiter, published by Collins, Sons, and Company, may suit, and the special terms can be found in most cyclopædias. There is a "vocabulary of definitions" in G. F. Chambers's work, Vol. II., "Instruments and Practical Astronomy," published by the Clarendon Press, Oxford.

J. J. G.—We believe it is the firm mentioned. You will understand that it was impossible to answer before, as the printing of the number was nearly completed when your note was received.

E. C.—Thanks; but the subject of the sailing of birds has been discussed to rags in back numbers, and we cannot reopen the controversy.

GLASS plates cast with wire gauze inclosed, submitted to tests in Vienna, have been found to possess consistency as well as resistance to pressure, shock, and the effect of heat, the resistance being 361lb. per square inch, and the consistency 3,610lb. per square inch of the transverse sectional area. The figures given are peculiar.

DR. LUDWIG MACH is reported to have successfully alloyed aluminium with magnesium, and thereby obtained a compound which can be worked like brass, and which is lighter than aluminium. A 10 per cent. magnesium alloy resembles zinc, a 15 per cent. alloy is like brass, and a 25 per cent. like a compound bronze. It is stated that the alloys can be soldered, and that they keep well in dry and damp air, and give good castings. The old proverb about the pudding comes in.

IN connection with the electric-supply stations in the County of London, it is stated that the boilers in use are divided as follows:—Water-tube, 75·5 per cent.; marine, 11 per cent.; Lancashire, 5·5 per cent.; miscellaneous, 8 per cent.; while the engines are:—High-speed, 62·5 per cent.; low-speed vertical, 25 per cent.; low-speed horizontal, 6·25 per cent.; special, 6·25 per cent. Direct coupling is universal.

TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

6s. 6d. for Six Months and 11s. for Twelve Months, post free to any part of the United Kingdom. For the United States, 13s., or 3dol. 25c. gold; to France or Belgium, 13s. or 16f. 60c.; to India, New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-Office Order. Back numbers can also be sent out by the ordinary newspaper post at the rate of 3d. each.

Vols. XXIV., XXX., XXXII., XXXVI., XXXIX., XL., XLII., XLIII., XLIV., XLV., XLVI., XLVIII., L., LI., LII., LIII., LIV., LV., LVI., LVII., LVIII., LIX., LX., LXI., LXII., LXIII., LXIV., LXV., LXVI., LXVII., and LXVIII., bound in cloth, 7s. each. Post free, 7s. 7d.

Indexes to Vol. LI., and to subsequent Vols., except Vols. LIII., LV., LVI., LVII., LIX., LXI., 3d. each, or post free 3½d. Cases for binding 1s. 6d. each.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each post free from the office (except index numbers, which are 3d. each, or post free 3½d.)

NOTICE TO SUBSCRIBERS.

Home Subscribers receiving their copies direct from the Office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a Pink Wrapper, as an intimation that a fresh remittance is necessary if it is desired to continue their subscription.

Foreign Subscribers will have the Pink Wrapper sent One Month before expiration, in order to give them time to forward fresh remittance before subscription expires.

ADVERTISEMENT CHARGES.

The Charge for Advertisements in the Columns headed:—

For Exchange.
For Sale.
Wanted.
Addresses.
Situations.

is Sixpence for the first Sixteen Words, and Sixpence for every succeeding Eight or part of Eight, which must be prepaid. *No* reduction on repeated insertions. Advertisers should state under which heading they wish their announcements to appear.

The address is included as part of the Advertisement and charged for. No displayed Advertisements can appear in above columns. Rates for Displayed Advertisements are as follows:—

For advertisements on inside pages, except page facing leader, for less than a quarter-page; per inch single column—

1	6	13	26	52 insertions
7s. 0d.	6s. 6d.	6s. 0d.	5s. 6d.	5s. 0d. each.

Per Column.—

Per Page	8 8	7 0	6 0	5 5	5 0 each.
Half-page	4 10	3 15	3 10	3 0	2 10 „
Quarter-page	2 10	2 5	2 0	1 15	1 10 „

Back Page, £10 10s. A few dates open during 1899.

ORDINARY ADVERTISEMENTS.

	£ s.
Thirty Words	2 6
Every Additional Eight Words	0 6

Front Page, Five Shillings for the first 40 words, afterwards 9d. per line. Displayed Advertisements, 10s. 6d. per inch. Paragraph Advertisements, One Shilling per line. No Front Page or Paragraph Advertisement inserted for less than Five Shillings.

All Advertisements must be prepaid, and in cases where the amount sent exceeds One Shilling, the Publisher would be grateful if a P.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.'s.

Advertisements *must* reach the Office by 1 p.m. on Wednesday to insure insertion in the following Friday's number.

For the convenience of advertisers, replies to advertisements (except those in the Exchange and Sale Columns) may be addressed to "———," care of the English Mechanic Office, and will be forwarded by post to the advertiser, for an extra fee of Sixpence per insertion over and above the cost of the advertisement.

All Cheques and Post-Office Orders to be made payable to The Strand Newspaper Company, Limited, and all communications respecting Advertisements should be distinctly addressed to:—

THE PUBLISHER,
THE "ENGLISH MECHANIC,"
332, STRAND, LONDON, W.C.

This is necessary, as there are several papers published at the same address, and unless letters are fully directed, it is impossible to tell for which paper they are intended.

For Exchange.

The charge for Advertisements in this column is 6d. for the first 16 words, and 6d. every succeeding Eight, which must be prepaid.

Special Notice. — *Correspondents are strongly recommended not to send money or goods to strangers. The safest way when dealing with unknown advertisers is to send a Post Office Order made payable —— days after date, when in case of non-arrival of goods, or dissatisfaction, payment can be stopped.*

Printing Press and Type, outfit complete, value 50s. Offers, cash or exchange.—Apply Adams Bros., Daventry.

1-horse **Engine and Boiler**, £12 or exchange for Screw-cutting Lathe.—Parkes, Alexandra-road, Richmond, Surrey

Wanted, **Magneto Generator**, with Bell. Give Howe Treadle Needle-work Machine.—9, Stuart-street, Luton, Beds.

Reflecting Telescope Mirrors made to order for cash or exchange.—David Booth, The Fall, Bramley, Leeds.

6½in. **Equatorial Reflector** (Calver), heavy iron stand, slow motion, fine instrument; exchange refractor, or sell. Seen by appointment.—C., 16, Sunningfields-crescent, Hendon, N.W.

In exchange for 1s. 2d. you will receive the best Engineer's Pocket Book published. Read on.

In exchange for 1s. 8d. you will receive the "Practical Engineer" Pocket Book and Diary. The greatest marvel of engineering literature published. Read on.

The Technical Publishing Co., Ltd., publisher of the "Practical Engineer" Pocket Book, 31c, Whitworth-street, Manchester.

"Ross" Microscope (new) and accessories; want, Back-geared Screw-cutting Lathe.—Miles, 57, Ashbourne-street, Leicester.

For Sale.

The charge for Advertisements in this column is 6d. for the first 16 words, and 6d. every succeeding Eight, which must be prepaid.

New Illustrated Price List of Screws, Bolts, and Nuts for model work, drawn to actual size, sent on receipt of stamp.—Morris Cohen, 132, Kirkgate, Leeds.

Watch and Clock Tools and Materials. Catalogue, over 1,000 Illustrations, post free, 6d.—Morris Cohen, 132, Kirkgate, Leeds.

Wheel-cutting and Dividing in Brass or Iron to 12in. diameter.—Clegg, Belinda-street, Hunslet, Leeds.

Lathes and Machined Parts, Wheels, Chucks, Fans, Angle-plates. Illustrated list, 2d.—Jarratt, Queen-street, Leicester.

Eyesight.—All whose sight is in any way defective should send to Horne and Thornthwaite, 416, Strand, for—

"Hints on Spectacles" (Why the Eyes want Help), by Overstall, F.S.M.C. (with distinction), post free.—Above.

Rubber Outer Covers, 8s. 6d. **Prepared Canvas,** 90 by 9, 1s. 3d.; rubber solution, best quality, 1lb. tins, 1s. 6d.—Pemberton.

Air Tubes, all sizes, best quality, 2s. 9d. each. Air tubes with Dunlop valves fixed, 3s. 9d.—Pemberton.

Cushion Tires, 3s., 4s., 5s. Solid Tires, 3s. All sizes stocked.—Pemberton.

Detachable Outer Covers (Licensed), 12s. 6d. each; all cycle accessories and cycle rubber goods stocked.—Pemberton and Co., 1, Cardwell-place, Blackburn.

50,000 Choicest Microscopical Objects.—Bargains. Catalogues free. Microscopes, cabinets. Collections purchased.—Suter, 10, Highweek-road, Tottenham.

Nuts and Bolts for Model Work. Illustrated List, 2,800 varieties, 3d.—Butler Bros., Haggerston, London.

Screws, Screw-plates, Taps, round and hexagon special steel brass and iron rods. See list.—Butler.

"Simplex" Gas and Oil-Engines, new series, "Otto" principle, ½B.H.P. to 2B.H.P., from £9. Guaranteed.—Below.

"Demon" Gas-Engines, awarded prize medal, ½B.H.P. to 12B.H.P., low price, high efficiency, economical. Guaranteed.—Below.

"Demon" Gas and Oil-Engines are thoroughly reliable. First-class workmanship.—Pasley and Co., Sherborne, Dorset.

Rubber Outer Covers, average 16oz., Para rubber 5s. each.—Franklands.

Rubber Outer Covers, 8s. 6d. each, 36s. per dozen.—Franklands.

Cushion Tires, 3s., 4s., 5s. Solid Tires, 2s. 6d., 3s. All sizes stocked.—Franklands.

Air Tubes, best quality rubber, 2s. 9d. each. Fitted with Dunlop valve, 3s. 9d.—Franklands.

Air Tube, Para rubber. Marvellous value. Large stock to clear. Perfectly air-tight., 2s. each.; 21s. per dozen.—Franklands.

Cycle Capes, 3s. 6d., 4s. 6d., 5s. 6d. Also a few cycle Capes, guaranteed waterproof, 2s. 6d. each.—Franklands.

Detachable Outer Covers, licensed, 12s. 6d. each.—Franklands.

Saddles.—A clearing line in ladies' and gents' saddles, 2s. 6d. each, 24s. per dozen.—Franklands.

Inflators, 18in., 1s. 6d. each, 15s. dozen.—Franklands.

Bells.—Special line, double gong, usual price, 12s. dozen, will clear 6s. per dozen.—Franklands.

Prepared Canvas, 90 by 9, 1s. 3d. each, 12s. per dozen.—Franklands.

Pedal Rubbers, 6d. per set of four, 4s. 6d. per dozen sets; no rubbish.—Franklands.

Spanners, nickel, usual price, 13s. per dozen. Will clear a few dozen at 7s. 6d. per dozen.—Franklands.

Cycle Accessories and Cycle Rubber Goods. We hold the largest stock in the North.—Franklands, Astley Gate Blackburn.

Brass and Gunmetal Castings of finest quality. Prices on application.—Daniel Young, Witney, Oxfordshire.

Mail Cart Wheels and Perambulator Furniture.—Walker Bros., Primo Wheel Works, Sheepscar, Leeds.

A STITCH IN TIME SAVES NINE.

But you will save more than that by smoking the *Weekly Times and Echo* Cigar which only costs *twopence*, and is equal, if not superior, to any other cigar which costs three or four times the price. We are selling (and tobacconists all over the country can supply you if they like) this cigar as a gigantic advertisement, because we know that wherever the cigar goes the marvellous value we are giving smokers will be a matter of universal comment and astonishment. See that every cigar has the *Weekly Times and Echo* band round it, and is sold from a box similarly labelled and branded: otherwise you will not be sure of getting for twopence a cigar which would otherwise cost from three to four times the price.

"Speeco" Belting Syrup prevents slipping, and keeps belts in good condition; 1lb. sample tin, post free, one shilling.—Speeco Ltd., Suffolk-place, Bermondsey, London.

Gas-Engine Oil, 1s. 6d. gallon. Cheaper grade, 1s. Cotton Waste, Tallow, Packing, &c. Correspondence invited.—Under.

Polishes, Varnishes, Paints.—Large or small quantities, by rail or post. Benzoline, Gasoline, Mechanical Rubber Goods.

Why Burn Dangerous Oils? We have Safety Kerosene in barrels or drums. Refined quality only.—Under.

Lamps and Stoves Repaired. Wicks and Glasses of every kind. Low prices.—Jones Company, Bethnal Green.

"Electricity" is a bright, chatty, and practical journal, which everybody interested in the science should read. Fridays 1d. Of all bookstalls and newsagents.

Engines, Lathes, Dynamos, &c. See illustrated catalogue, price 4d.—W. Leather, Vernon-street, Hightown, Manchester.

"B" Oil-Engine Castings and Forgings. Easy to make; no complicated parts; very reliable.—Barkers, Leyton.

"B" Oil and Gas-Engines are fitted with silent gears, sensitive governors, adjustable bearings.—Barkers, Leyton.

Original Testimonials can be seen at any time, together with English and Colonial Press opinions.—Barker.

"B" Gas and Oil-Engines. Supplied the word over. Particulars stamp.—A. and S. Barker, Engineers, Leyton, E.

Launch Oil Engines a Speciality. New designs. High speed. Very reliable.—A. and S. Barker, Engineers, Leyton, E.

Money Saved is Money Earned.—The cheapest house for electric bells, telephones, light material, &c.—Write for catalogues, post free 3d., to C. W. Tebaches and Co., 165, Queen Victoria-street, London.

"Acetylene: its Characteristics, Generation, and Uses," with Descriptive Catalogue of "Incanto" Apparatus; just published, 3d. post free.—Thorn and Hoddle 1 Tothill-street, Westminster, S.W.

Gas and Oil Engines.

Steam Engines.

Dynamos.

New Designs. New Patterns.

Latest Improvements.

H. Warsop, Launder-street Works, Nottingham.

Simplex Typewriter, 14s. 6d., delivered. Thousands in use. Illustrated particulars free.—Atkinson and Co., Harehills-avenue, Leeds.

Model Boiler Fittings and Material, seamless copper tubes, 5-32in., 3-16in., ¼in. up to 8in. diam.—Below.

Steam Gauges from 1in. dial, 60lb., 6s. Warranted ¼in. Wheel Valves, 3s. 11d.; Water Gauges, &c.—Below.

Injectors, Cylinder Lubricators, Lever Safety Valves, Copper Rivets and Sheet Brass and Steel Rods, &c.—Below.

Illustrated Catalogue of above high-class gun-metal fittings, 2 stamps.—Bert Garside, Golborne-street, Warrington.

Brass Casting Made Easy by using Wells' specially prepared Moulding Loam. Brass casting a pleasure.—Below.

Sold in 5lb. canisters, 2s. 3d.; 10lb., 3s. 9d.; 20lb. 6s., carriage paid, with instructions.—Below.

Plumbago Crucibles, with instructions for melting brass, sixpence each post free.—Geo. Wells, Needham Market Suffolk.

Best Carbide, 28lb. 8s. 6d. Acetylene Burners, 1s. 6d. dozen. Generators, Limelights, &c. List, stamp.—Houldershaw, Liversedge.

"Suter" for Accumulators. 4-volt, curved, 5-hours light, 4s. 6d.; 4-cell charging battery, 4s.—Below.

Large Illustrated List. Electrical and Mechanical Novelties, two stamps.—T. W. Suter, Highweek-road, South Tottenham.

A Perfect Portable Home Turkish Bath, folds into 3in. space, weighs 7lb.—Gem Supplies Co.

The Folding Quaker Bath Cabinet. Cleanses and invigorates, cures diseases without nauseous drugs.—Gem Supplies Co.

A Turkish Bath for a Penny. "E.M." pamphlet free.—Gem Supplies Co., 6, Bishop's-court, Chancery-lane, London.

"Perfect" Pocket Oiler, emits one drop at a time, never leaks, 1s. each.—Gem Supplies Co.

"Perfect" Pocket Oiler.—Best oiler for bicycles, typewriters, or sewing-machines, 1s. each—Gem Supplies Co.

"Perfect" Pocket Oiler, 1s. each. Trade terms on application.—Gem Supplies Co, 6, Bishop's-court, Chancery-lane, London.

Phonographs, new Gem, take standard records, and are fully licensed, £2 2s.—Below.

Phonograph Records, Bands, Songs, Instrumental Speeches, 2s. 6d. each, post free 2s. 9d.—Below.

Phonograph Accessories, &c.—T. G. Woods and Sons, 51, Spencer-street, Clerkenwell, E.C.

Astronomical Telescopes bought, sold, or exchanged.—Clarkson and Co.

Astronomical Telescope Parts, eyepieces, finders, Barlow lenses, repairs.—Clarkson and Co.

Astronomical Telescopes on Loan.—Clarkson and Co., 28, Bartlett's-buildings, Holborn-circus, London, E.C.

Astronomical Telescopes to view the shooting stars.—Clarkson and Co.

Astronomical Telescopes, 2¼ Dollond, £4 10s.; 2¼ Wray, £6 10s.—Clarkson and Co.

Astronomical Telescopes.—3in. Solomon, £4 10s. 3in. Newton, £4 10s.; 3in. Hughes, £4 10s.—Clarkson and Co.

Astronomical Telescopes.—3¼ Lancaster, £12 10s. 3¼ Wray, £16 10s.—Clarkson and Co.

Astronomical Telescopes.—4in. Wray, £25.; 4in. Crichton, £18 10s.; 4in. Cooke, £30.—Clarkson and Co.

Astronomical Telescopes.—4½in. Browning reflectors, £6 10s. 6½in. Browning, £20. 8½in. Browning, £25.—Clarkson and Co.

Astronomical Telescope, 4in., Cooke equatorial, and Driving Clock, on iron column complete.—Clarkson and Co.

Astronomical Telescope, 3in., with equatorial mount and garden stand, £15.—Clarkson and Co.

Astronomical Telescopes.—Full details on application to A. Clarkson and Co.

The English Mechanic
AND WORLD OF SCIENCE AND ART.
FRIDAY, DECEMBER 8, 1899.

INLAYING.—IX.

Brackets, &c.

THE two designs of brackets are to give an idea of a support, yet avoiding any appearance of clumsiness. The object of a

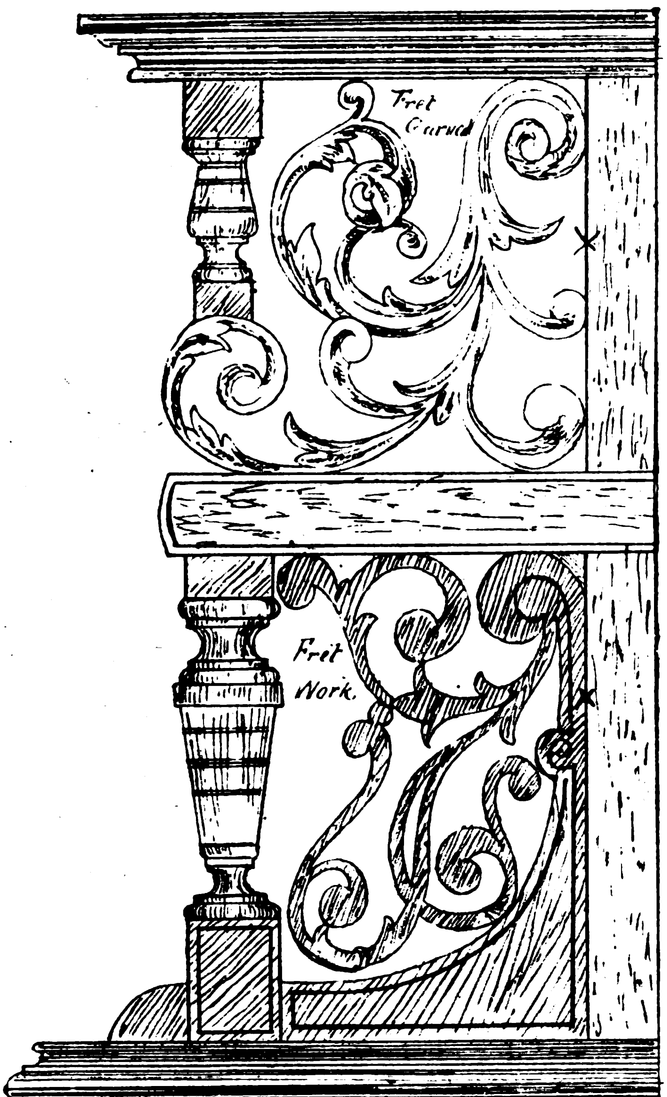

Fig 144

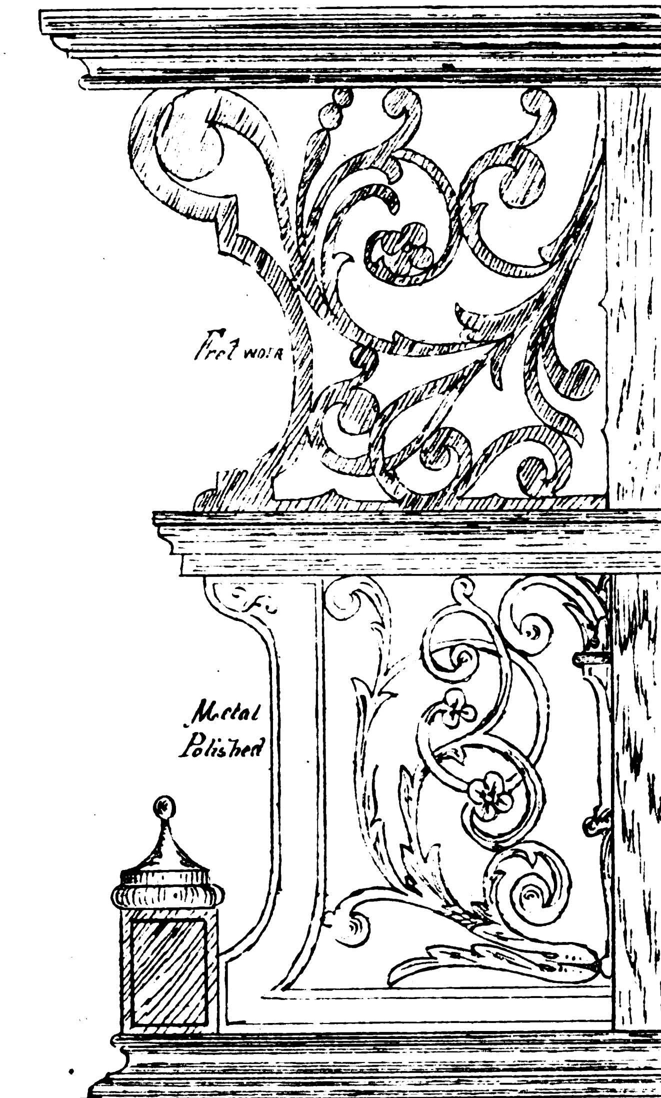

Fig 145

support can always be got, that looks and gives strength yet does not look heavy.

The upper portion of Fig. 144 is intended to represent fretwork carved on its outer faces, and should be of such substance as to admit of the little short column, the bottom of which is hollowed out to follow the sweep or curve of the ornament. A little short pin or dowel should be turned on the top and bottom of the column, which can be put in position when the two shelves are fixed together. The same applies to the bottom ditto. With this exception the bottom square of large column can be opened to receive the fretwork panel, or a little ¼in. round block can be glued afterwards. The black line represents a little inlay or stringing; not the lines X X—they are the face of the bracket-back. Fig. 145 gives the upper part fretwork only and the bottom panel in metal, polished and engraved. The bottom block should have a little stringing, the same as Fig. 144. The turned pinnacle is fixed with a short dowel entering into the block.

The work itself can be in mahogany or any other dark wood, but not light wood with brass. If a lighter wood is used, then copper, polished and lacquered, should harmonise. Much will be gained by trying the effect of different colours, as to blending, &c. The four examples are of richer repeating designs, and can be cut in either wood or metal; but the bottom, Fig. 149, is intended to be in metal and richly engraved.

The two chair-backs (as shown in Fig. 150) are respectively of "Sheraton" and "Hepplewhite" styles, and are given as typical fretwork cutting with carved enrichments. The cutting will require chopping in, or cut in a ground and carefully veneered to the back. The other two, Figs. 152 and 153, are merely to give an example of doing away with a plain part, existing on old chairs as a rule, and substituting the better or nearer approach to the work of the old masters.

The above are given because the demand for imitations of the works of the last century is greater now than in former years; consequently they are foundation examples of other modifications that may occupy the attention of the student at future times. The addition of a little stringing has often the effect of decidedly enriching and enhancing the value of the furniture, independent of the good practice that it gives.

Where the frames are so contracted as to admit of a little corner bracket under the seat frame, it is but little trouble to add it. Especially is that the case if fretworked, either carving or letting in a little stringing. Much can be done to beautify an otherwise plain piece of furniture, and what is the cost?—trivial at the most, compared with the satisfaction that it must give.

At Fig. 154 will be seen a centre, or group of musical instruments. Such groups were much in vogue, and were not only cuttings in different kinds of wood, but metal was introduced, which gave an effect that stamped it at once as art work. The music and finer portion are supposed to be engraved, but we have seen the notes, signs, &c., actually cut in, and beautiful work it was. The aim, as in all cutting, is to get as much relief as possible, and if, in choosing the different wood to suit each instrument, the contrast is not too great yet sufficient to fully depict each article, the result must undoubtedly give entire satisfaction.

For instance, the music-book would naturally be in white wood; the centre single-reed horn of peartree, the old guitar in darker pear, with satinwood bands interposed in the body as at A A. The clarionet could be in darker pear (dyed a shade darker) with the keys and other appurtenances of a light wood to gain a fair contrast. The cornet could well be in a wood of yellowish tint so as to approach a brass colour, and the other ancient-looking guitar should be yet a shade darker in the border with a black stringing or line let in to gain an equal

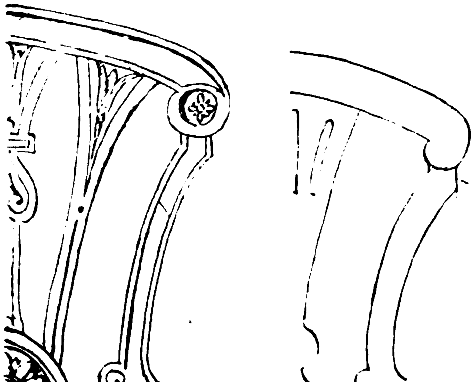

Fig 152

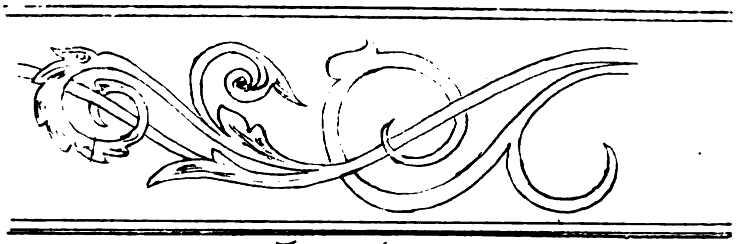

Fig 146

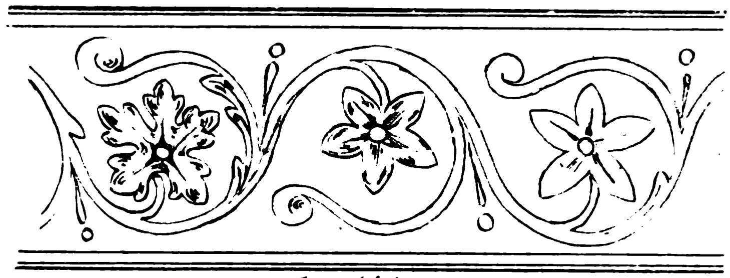

Fig 147

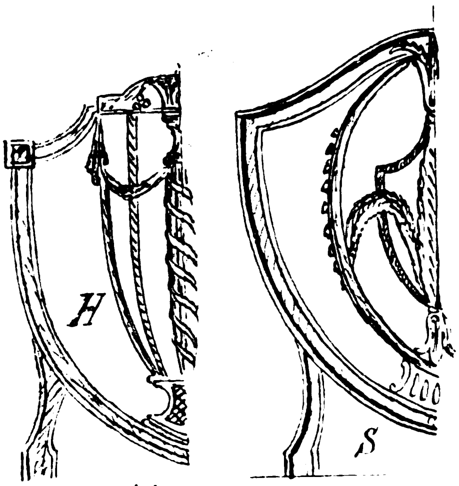

Figs 150

Fig 148

Fig 149

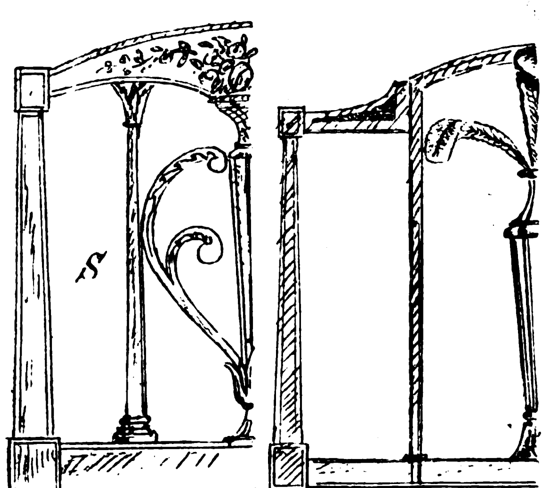

Fig. 151

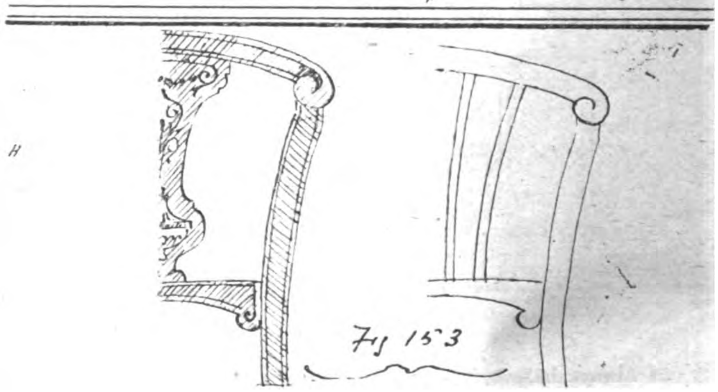

Fig 153

margin, and the strings themselves bodily cut in, using black lines to show up boldly. The pipe could be in satin or boxwood, well shaded with bands of blue (dark) or a deep violet. Although not usually seen as described, the slight enrichment will not tend to gaudiness. The riband and bow can be in a rich blue, and if carefully shaded should give a fair result. The outer border can be in yew-tree, and the ground in rosewood.

Mosaic.

The preparation of the medium can be either marble, imitation stone, or of glass. Whichever is resorted to, many colours and shades or tints of the different colours are needed. It will scarcely be necessary to say much about marble, as any colour can be got in the natural state; that is to say, thin slabs of marble in all variety of colours are procurable, and are cut up into minute squares with tools of chisel form so fixed in a sliding frame, permitting the veneer or slab to be scored, afterwards to be broken up into the small square form that is necessary for assembling. Glass will have to be scored with a diamond, in the same manner as grating lines or divisional lines used in microscopic and telescopic work, one set of lines on one side, the other at right-angles on the other; the diamond should not cut across the cuts already scored.

The pigmented tissue, or medium, is made with the finest sifted Portland cement, and while in the liquid state, extra fine dry colours are added to obtain the colour necessary. Upon a clean sheet of glass, smear over the surface some vaseline. Upon your glass bed—which, by the way, should be at least ¼in. thick—attach, by means of varnish or other medium that is not soluble in water, two thin strips of either glass (which is certainly preferable) or wood just 1/16in. thick. The distance between the strips is governed by the quantity of artificial coloured stone intended to be made up. A piece 3in. square will cut up into many little squares, and leave a fair margin for breakage. The medium of coloured plaster being ready, and well fluid, is spread carefully over the glass bed; a thin layer at first, and when just a trifle set another application will be needed until the medium is perfectly level with the two glass guide slips. Be sure and have the thickness even, for reasons to be explained.

When the bulk is semi-dry, which can easily be tested with separate slabs (they

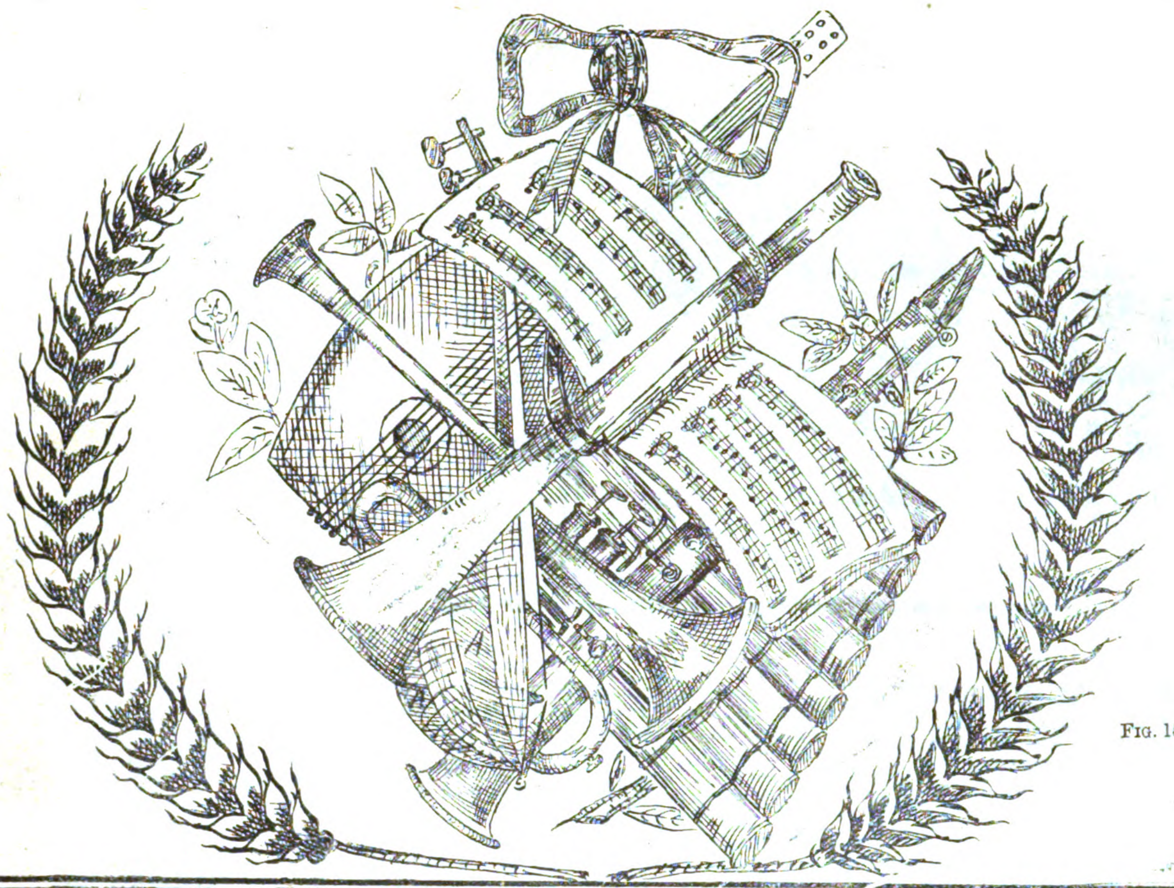

FIG. 154.

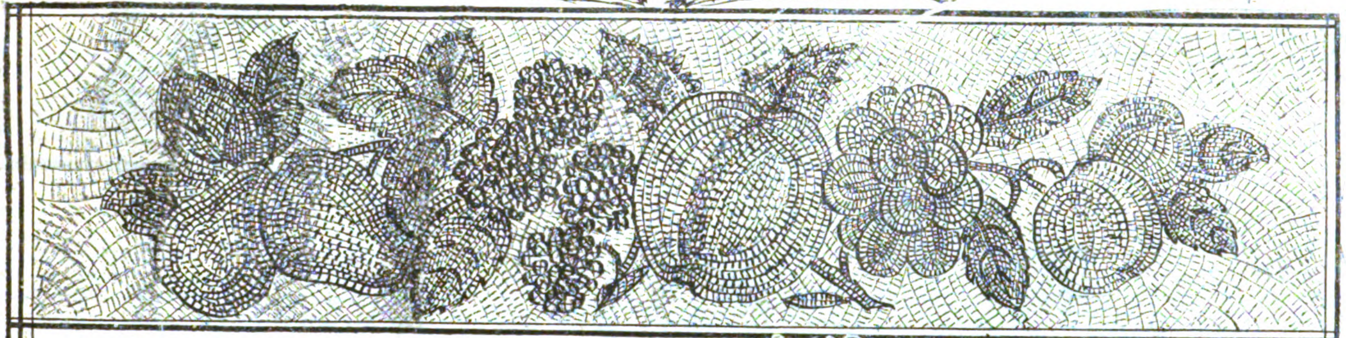

FIG. 155.

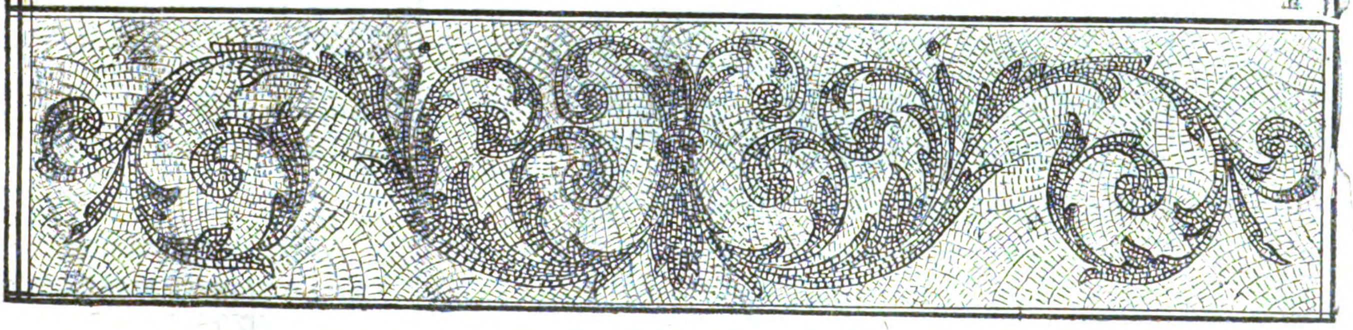
FIG. 156.



need not be more than about 1in. square), a simple contrivance must be made to divide the medium ere it is too dry. The easiest and quickest way is by laying a guide-piece at the left-hand opening in the slips. Against the guide a number of small strips are packed side by side until they cover the whole of the 3in. square. With a thin knife, not necessarily sharp, a cut is made across the medium. By lifting a strip in its turn, the cuts will consequently be the substance of the strip apart—viz., $^1/_{16}$in., and so on in rotation, lifting a strip each time a cut has been made. We shall then get a slab of coloured cement with 48 cuts $^1/_{16}$in. apart; if the cuts have been carefully made they should still retain their position on the glass bed. The same course of operation must be made the reverse way, or, rather, at right angles. The medium should be set aside to dry and harden; it will be found an easy matter to separate them afterwards.

A shallow tray will be wanted, with divisional pieces to form a number of small square boxes. As the coloured cements are made and cut, so should they be placed each in its respective box; otherwise it will be a difficult job to pick out the different tints from a bulk of mixed pieces, irrespective of the time lost in searching.

The first stage is to trace out the design upon the paper spoken of in the first part of this treatise. A piece of glass will now be wanted, which should lie upon the design. On the exposed face of the glass smear or spread some adhesive matter; for our uses, white of egg or gelatine will answer well—to which is added a trace of glycerine, because it must not dry too quickly. Yet we shall be obliged to keep on adding a little as we progress in our work. Two friezes are given in Figs. 155 and 156, and, if copied, will enable the student to get out any others he may want. When the whole of the surface is covered, it should be placed aside. To get it off the glass, a very thin blade should be passed between the glass and the mosaic; or, if it is desired to have it as a specimen, a layer of ordinary cement can be spread upon the assembled mosaic. When that is thoroughly dry, the glass bed can be warmed in hot water up to a degree of heat that will enable the mosaic to strip easily.

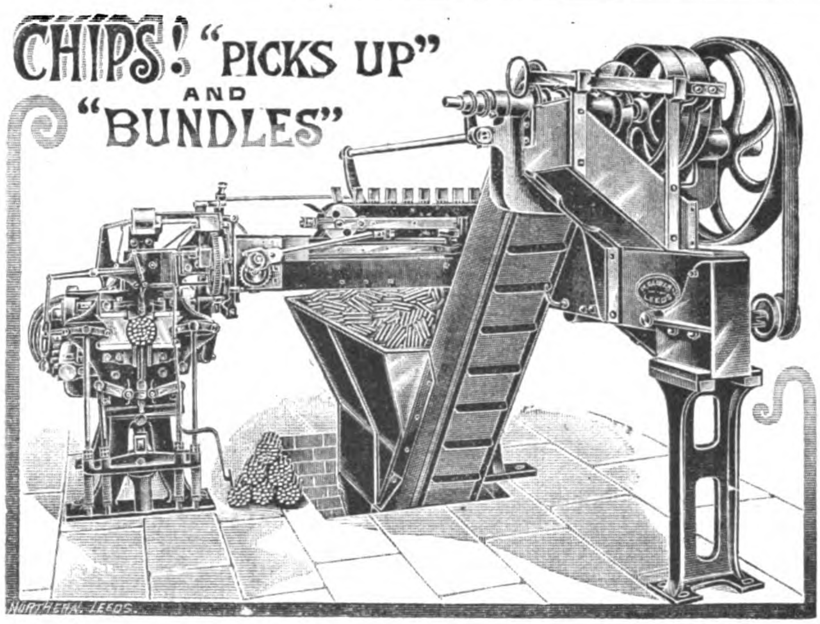


FIG. 1.

WOOD-WORKING MACHINES.

MESSRS. M. Glover and Co., wood-working machinists, Leeds, keep to the front with their novelties and improvements in connection with machinery for "sawing," "splitting," "picking up," and "bundling" firewood, &c.; but it is quite impossible to describe them in a short article like this, and, therefore, we would advise our readers to personally inspect the various appliances in operation, which would much interest and repay them.

Messrs. Glovers' "patent mechanical chip, picking-up, and arranging machines" are capable of a variety of modifications to suit various premises and positions of plant. This work is generally done by hand, and is found most tedious and expensive, and for many reasons a complete nuisance to employers, and, until recently, it has been considered impossible that such difficult manipulations could ever be accomplished by anything short of a mind. These appliances are, however, now a perfect success, and in practical use, though it has taken Messrs. Glover several years of thought and experimenting, as sticks may only be "coaxed," and not "coerced."

Our first illustration shows one of these patent chip arrangers. As the sticks are sifted, they drop into narrow spouts, compelling them to assume a uniform position lengthways, in which direction they are shot forward by quick travelling belts into narrow travelling boxes, working on the top of a belt, approximately as wide as the sticks are long. By an ingenious arrangement of "clapper" the sticks are placed perfectly straight in these boxes, or else are made to drop out, in which case they travel back, and are made to do the journey again. Though the apparatus saves so much labour, it is most compact and simple to work, occupying very little floor space.

The illustration marked Fig. 2 shows the patent "Ideal" saw-guard made by this firm, which, though quite a new invention, has already met with a large sale, owing, we believe, to the fact of its being a thoroughly practical and well-designed arrangement, having been tested and

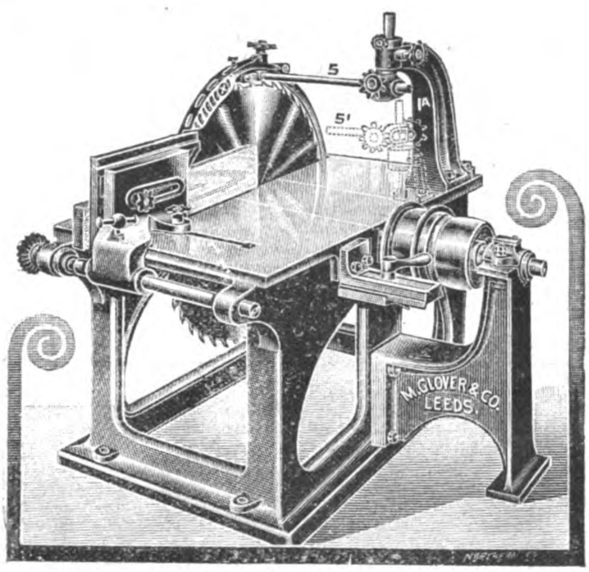

FIG. 2.

adopted by many firms previously prejudiced altogether against guards, and we are given to understand that Messrs. Glover and Co.'s "Ideal" guards have time after time given perfect satisfaction when other guards have been found quite useless, obstructive, and, in several cases, dangerous.

In saw-guards, especially, we consider the greatest care is necessary in selecting the most perfect appliance possible, both in the interests of men and masters. Guards to be valuable should not hinder the work in the slightest, nor give sawyers extra labour, and should protect whilst the saw is being used. Some guards only appear able to "box in" the saw when the saw is not being used, which is just when the saw is not dangerous: but the "Ideal" claims to give the greatest possible protection when working, and it allows of sawing as deep as ever the saw will cut.

Various styles of brackets are supplied, as may be preferred, and, if desired, these guards can be supported from above or at the side, leaving top of bench quite free.

Fig. 3 shows an improved saw-sharpening machine, also made by Messrs. M. Glover and Co. By aid of this machine "punching" and its attendant evils may be entirely dispensed with. This is a great saving, as saws will, in consequence, last considerably longer, and "hammering" is almost entirely done away with. The most experienced "hand-saw sharpener" is obviously only able to file the teeth of the saws quite straight, and, certainly, the frequent liability is for him to file them round, whereas by means of the circular revolving emery-wheel in this machine the teeth are compelled to be slightly hollow, like a skate-blade. Thus they are rendered much sharper, and, therefore, cut sweeter and remain sharp longer than if sharpened by hand. By very easily adjustable contrivances all the various "angles" and "leads" required in the saw-teeth

FIG. 3.

may be secured, and by a "stop motion" (the emery-wheel lowered to a given point for each tooth) the teeth are accurately sharpened to one height; thus each tooth must do an equal amount of work, whereas in the most usual irregular hand-sharpening it is of necessity all guesswork, and not infrequently it may be found that more than half the teeth in a saw are simply doing no work at all, as they are topped shorter than others. In this improved machine "Glover's Special Emery Wheels" are used, and the temper of the saws is kept intact by a fine cold spray of water ejected exactly on the tooth being operated upon. There is also one long, continuous leather belt driving the emery-wheel, thus preventing the stopping of the emery-wheel when cutting. We recommend our readers to write to Messrs. M. Glover and Co., patentees of the above inventions, to their address at Holbeck-lane, Leeds where fuller particulars may be obtained.

MILLWRIGHT'S WORK.—XIX.

ROPE-DRIVING is having a good innings now, and it has advantages in many respects. But the assumption that it is going to displace leather for ordinary service would be too gratuitous. For certain purposes it is admirable, but not for every kind of service. Though ropes are cheaper than belts, their pulleys are much more costly. Then there is the difficulty of getting every rope to do its proper share of the work, which has resulted in the use of tightening pulleys, an awkward arrangement when many ropes are engaged in driving. Besides, the belt makers have not been asleep, and they now understand better than they did the most suitable conditions under which belting can be driven. Nevertheless, rope transmission has so many advantages in the case of long drives, drives of great power, and twisted drives, that it has taken a place that will be permanent in the work of the millwright.

Manila hemp and cotton are the two materials

TABLE OF HORSE-POWER OF MANILA ROPES (C. W. HUNT AND CO., NEW YORK).—SPEED OF THE ROPE IN FEET PER MINUTE:—

Diameter of ropes in inches.	1,500	2,000	2,500	3,000	3,500	4,000	4,500	5,000	6,000	7,000	8,400	Smallest diam. of pulleys in inches.
½	1·45	1·9	2·3	2·7	3 0	3·2	3 4	3·4	3·1	2·2	0	20
⅝	2·3	3·2	3·6	4 2	4·6	5 0	5·3	5·3	4·9	3 4	0	24

1½	13·1	17·4	20·7	23·1	26·8	28 8	30·6	30 8	28 2	19 8	0	60
1¾	18 0	23·7	28·2	32 8	36·4	39 2	41·5	41 8	37 4	27 6	0	72
2	23·1	30·8	36·8	42·8	47 6	51 2	54·4	54·8	50 0	35 2	0	84

NOTE.—The above Table assumes an arc of contact of not less than 170°.

used for ropes. When properly made, and used under suitable conditions, there is little, if anything, to choose between the two. These conditions are of so great importance that they make, in extreme cases, a difference between a few months, and six, eight, or ten years in the life of the rope.

A rope differs from leather or chain in this: that, though subject to direct tension, the fibres, yarns, and strands are twisted. The amount of twist permissible has been settled by experience. But in any new rope, some amount of stretch results, which has to be taken up by resplicing two or three times, after which it stretches no more. In manufacture, the yarns, the strands, and the completed rope are successively twisted in opposite directions, in order to neutralise the twists as far as possible. The strain on a rope tends to untwist the strands in one direction, and yarns in the other direction, until the two are approximately balanced. Ropes are made of three or four strands; some prefer one, some the other. A four-strand rope must have a heart, or core, a three-strand none. A four-strand has a section more nearly circular than the three.

It is clear that a rope is, in two respects, more unfavourably constructed than a belt to endure bending over pulleys. In the first place, its thickness is much greater; in the second, its fibres are more delicate. The practical issue is that the pulleys for rope must be much larger than those used for leather belting, and that their grooves must be smooth and polished to prevent fraying of the delicate rope fibres. There are, therefore, internal and external friction to be minimised.

The fibres of which the rope is built up rub over one another within the rope, tending to break up its structure and reduce it to powder. This is the evil which has given most trouble to rope users. To prevent or diminish the internal friction of the fibres of the rope, which on small pulleys is rapidly destructive to the fib es—grinding them to powder—is the reason why the pulleys must be as large as possible. There are minimum diameters which are fixed by experience, but it is better to exceed these when possible. Besides this, manufacturers lubricate the ropes when in process of manufacture. The C. W. Hunt Co., of New York, employ plumbago mixed with tallow. This renders the rope also partially waterproof, and, after a little wear, it becomes permeated and coated externally, and hardened by the lubricant. In addition to this, it is well to apply a preparation to the outside of the rope from time to time, especially when it is exposed to weather.

An approximate rule is, that a pulley should not measure less than forty times the diameter of its rope. Mr. Coombe gives the following sizes as agreeing well with practice:—

1¼in. diam. rope,	3ft. diam. pulley,	ratio	1	to	28·8
1½in. „ „	4ft. „ „	„	1	„	32 0
1¾in. „ „	5ft. „ „	„	1	„	34 3
2in. „ „	6ft. „ „	„	1	„	36·0

When the size of a pulley must be reduced much below proper proportions, then an alternative is to reduce the diameter of the ropes, and to increase their numbers.

Another important point in rope-driving is the speed. This ranges most economically at between 3,000ft. and 5,000ft. per minute, and experiment has demonstrated that nothing is to be gained by going beyond 5,000ft., because the centrifugal force increases more rapidly than the additional power gained, and so reduces the latter.

The following useful table by the C. W. Hunt Co., of New York, gives the horse-power of their manila ropes, and the diagram (Fig. 123) shows the same results plotted. The basis is a working strain of 200lb. on a rope 1in. in diameter, and is about one-twentieth of the breaking-strain at the splice.

In calculating the table, the effect of centrifugal force has been estimated, and the curious result is seen that the horse-power lessens rapidly as the speed gets beyond about 80ft. per second. The total stress on the rope is the same at all

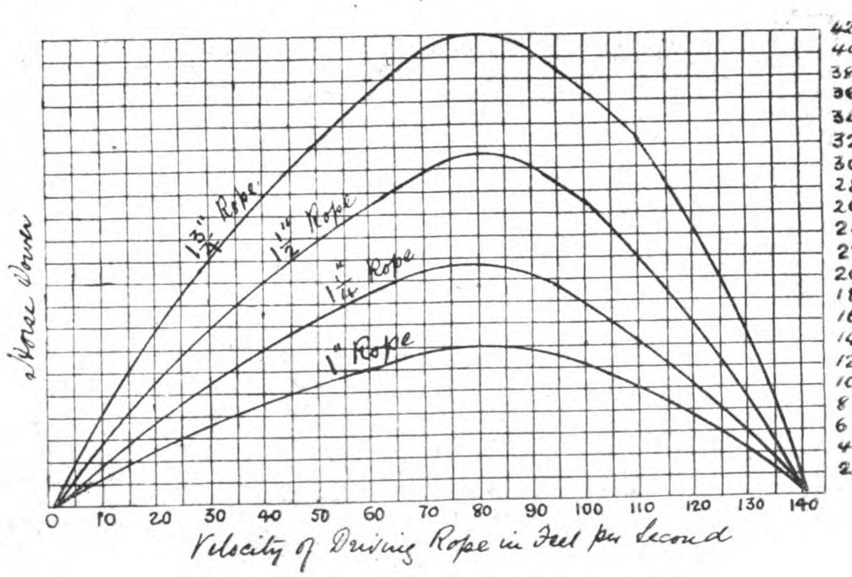

FIG 123

speeds given in the table. With a given velocity, the *weight* of rope required for transmitting a given horse-power is the same, no matter what size rope is adopted. The smaller rope will require more parts, but the gross weight will be the same.

Another and most important point is the stress on the rope. About 7,000lb. is the ultimate strength of a rope 1in. in diameter; but the

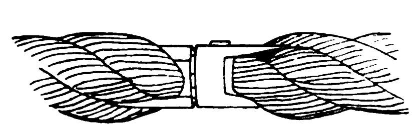

FIG. 124.

working strain should not be more than 200lb., giving the enormous margin of 35 times. Actually it is less than this, because the strength of the splice is less than that of the solid rope; but the working stress may be taken here as being from $\frac{1}{20}$th to $\frac{1}{25}$th the strength of the joint. This is an enormous margin; but experience of short-lived ropes has demonstrated its necessity. The question is not so much one of static strength as of dynamic working—conditions which cannot be calculated, but which are found to produce rapid wear.

If a rope is overstrained, the result is seen in the strands becoming loose, due to the partial untwisting of the rope. A rope may wear badly on the outside, even though the pulleys are of ample size, due to the roughness of the pulley grooves, or to their running out of truth, or to adjacent ropes chafing against each other, caused by the bad fitting of pulleys, or too fine pitch of the grooves, or too much sag.

In rope driving there is a large amount of sag to be allowed for. If a rope is pulled up too tightly, it will not last nearly so long as when slack. The limit to sag and slackness is that at which the rope begins to slip. The sag on the driving side is taken as a constant for all speeds, because the tension should be always the same. But the sag on the slack side varies with speed, increasing as speed diminishes.

The splice of a rope is its weakest part, and generally goes first. It must be long, measuring not *less* than from 6ft. to 12ft. It must be so made that the diameter at that part shall not be sensibly larger than the diameter elsewhere. The C. W. Hunt Co. give the following table for the length of splices:—

Diam of rope.		Length to allow for splicing.
¾in.	....	9ft.
⅞in.	....	10ft.
1in.	....	12ft.
1¼in.	....	14ft.
1½in.	....	16ft.
1¾in.	....	18ft.
2in.	....	20ft.

This firm insert a coupling, Fig. 124, in their ropes by which the resplicing under ordinary conditions is avoided. The coupling is fitted to the rope-ends, and permits of the rope being shortened by twisting it. The coupling is of aluminium bronze, to reduce weight, and, being smaller than the rope, is not open to the objection of striking the pulley grooves. A minor advantage of this is that twisting the rope slightly enlarges it, so compensating for wear. J. H.

LIGHTNING: THE "DARK" FLASH.

FOR some years past notes and letters have appeared in several of our science reviews about what has been called "dark" flashes of lightning, or simply "dark" lightning. To say the least about this supposed meteorological phenomenon, it is as difficult to conceive the physical constitution of such a flash as the special conditions necessary for its production.

The various phenomena of an electric storm are susceptible of explanation in general terms by considering the two charged bodies—say, a pair of clouds, or a cloud and the underlying surface of the earth—as the two coatings of a large condenser, the intervening mass of air constituting the di-electric. As in the analogous case of a Leyden jar, when the strain produced in the glass by the opposite charges becomes sufficiently great, the jar is perforated, so when the strain to which the air is subjected exceeds its "di-electric strength," it suddenly gives way along a line of minimum resistance. The displacement of electricity constituting the discharge gives rise to violent surgings forward and backward along the line of rupture, which surgings continue until the potential difference that caused them has been wiped out. This is effected in an exceedingly small fraction of a second.

The energy of this oscillatory discharge is communicated to the surrounding air, which becomes heated accordingly. We are made aware of this only when the released energy is sufficient to heat the air up to luminescence. It then affects our sense of sight, producing on the retina an effect depending on the form and intensity of the flash.

So far, then, as the eye is concerned, every flash of which it is cognisant is necessarily accompanied by some degree of luminosity. But, on the other hand, we have the testimony of persons whose veracity is as unimpeachable as their accuracy of observation is beyond dispute, that they several times saw in the sky tracks of discharges which were unmistakably dark. Such observations naturally demanded some consideration; the possibility of dark flashes was, therefore, entertained for a while, and theories put forward to explain their occurrence.

It was not long, however, before the astronomical idea of a "personal equation" suggested a retinal effect as a possible explanation. To many it appeared to be not only a possible, but a plausible explanation; and, indeed, the only one.

So, too, thought Lord Kelvin, when, one evening last August, at Aix-les-Bains, he was favoured with a vivid display of lightning. The opportunity was too good to be neglected, and he forthwith proceeded to put the retinal theory to a test. Looking out at the sky, a discharge occurred which gave rise to two well-marked flashes. He saw these distinctly as brilliant zigzags of light; but, on turning a few seconds later, to a part of the sky which was illuminated by another discharge, he saw—just as he expected—the former double flash dark on a luminous background.

To confirm this observation, he returned to the brilliantly-lighted drawing-room, where, on suddenly looking at one of the walls, he noticed precisely the same reversal. There was the dark double flash complete in every detail. This conclusively shows that the so-called "dark" flash is not a real physical occurrence, but merely a subjective effect. The part of the retina affected by a first flash is in a state of comparative fatigue, so that when a second one occurs it fails to respond as actively to the stimulus caused by the general illumination as do the surrounding nerve filaments, thereby giving the observer the impression of a well-defined dark flash.

However strong the evidence afforded by such observations, it was still urged by some that the case against dark lightning was not conclusively made out. They held that the matter could not be considered as finally settled until a satisfactory interpretation was given of the dark flashes noticed occasionally on photographs of lightning.

The photographic plate is, indeed, far more sensitive to the ether ripples that constitute light than is the network of filaments which form the retina. It is, moreover, neither nervous nor impatient, nor are its impressions inaccurate or evanescent; it is ever ready to give a faithful record as well of the invisible trail of a flying meteor as of faint specks in the star depths, whose very existence the largest telescopes fail to detect.

It was thought, then, that such a highly sentient recipient of radiant energy might possibly afford some information in favour of the objective reality of the dark flash.

This view was, however, finally negatived (*Proc. Phys. Soc.*, Vol. X.) by the researches of Mr. Clayden, who, knowing that the bright parts of a photograph could be reversed by exposing the plate before development to the action of diffused light, showed that the darkening of the flash was purely a chemical effect in the film, and that it could be reproduced at will. If the lens of a camera be covered the moment after a flash occurred, the developed image will always come out bright, feebly or strongly, according to circumstances. Mr. Clayden found, however, that if the plate be exposed after a flash has acted upon it, either to the continued action of a feebly diffused light, or to the powerful glare arising from one or more subsequent flashes, then on development the image of the original flash will probably come out black. This effect can be obtained not only with a lightning flash, but also with a spark from a Wimshurst machine or an induction-coil. "It is merely necessary," writes Mr. Clayden, "that the plate should be exposed to the action of a certain amount of light after it has received the impression and before development."

This interesting subject has been examined anew—quite recently—by Dr. William Lockyer. In studying photographs of lightning, especially some taken by himself during the past seven years, he noticed two varieties of the "dark" flash which he failed to detect in any photographs of laboratory lightning at his disposal. These were flashes which he describes as dark with bright cores and others, which are bright but with decidedly dark borders. For the full acceptance of Mr. Clayden's explanation, it appeared, therefore, necessary to produce these two types artificially, and it is precisely in this reproduction that Dr. Lockyer has been successful.

We now know the exact meaning of the black zigzags and their lateral ramifications which may be found in photographs of lightning, and we know also how the dazzling flash of our skies may be made to yield a dark retinal impression. The mystery has at last been cleared up. The term "dark" lightning is, therefore, a misnomer, corresponding to nothing real in nature, and as such it deserves to be dismissed for ever from our scientific nomenclature.

We find a few other terms in our literature which so richly deserve a similar fate that it is a wonder they were not long ago relegated to the profoundest depths of the limbo of oblivion—e g., thundertube, thunderbolt, thunderstorm.

Thunder is in no way concerned in the formation of the peculiar conical cavities sometimes formed in sandy soil by an electric discharge, and which early writers unwittingly called thundertubes.

Again, there is no such thing as a thunderbolt distinct from the lightning flash pure and simple. "A bolt from the blue," in the popular mind, means, we readily admit, an intensely hot solid mass which comes down in the wake of the flash. Now, everyone knows that meteoric masses visit us at all hours of the day and in all seasons of the year, as well before as during and after a storm. If, perchance, a mass rendered red-hot or white-hot by its rapid passage through a hundred miles or so of our gaseous envelope should chance to follow in the rarefied wake of a flash and crash down upon the earth, it is none the less a lump or matter of cosmic, and not atmospheric, origin. It is not a fireball of electrical formation, but simply a glowing mass of brute matter similar to the stuff of which this and other worlds are made.

Shakespeare, in "Cymbeline," Act IV. Scene 2, makes Guiderius bid his friend

> Fear no more the lightning flash,

to which Arviragus promptly adds

> Nor the all-dreaded thunder-stone.

Here the dramatist simply adopts the popular notion of his time. With all his intuition, he could no more have anticipated the meteoroidal views of the German Chladni, and Hubert A. Newton, of Yale, than the protective system against lightning recommended by Maxwell and developed by Lodge.

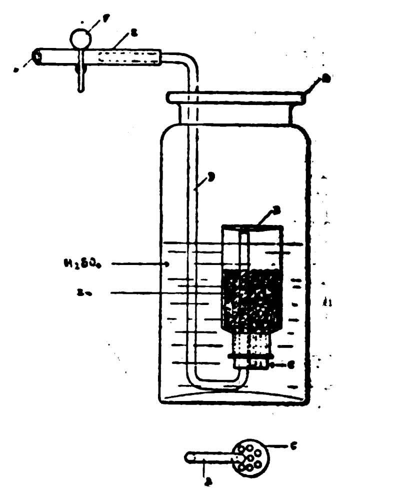
Even the term thunderstorm is objectionable, inasmuch as the crash or the peal, or the rolling noise that usually accompanies the electric discharge, is by far the less important characteristic of the phenomenon. Who speaks of a shower as a "patter" storm? Who would venture to describe a hailstorm in one of our daily papers under the title of a "rattle" storm? Is it not equally belittling and improper to speak of an impressive electric display as a "thunder"-storm?

We commend these curiosities of our scientific literature, together with such strange improvisations or importations as "black electric sparks," "X-light," "Becquerel light," and "dark light" (la lumière noire of Le Bon), to the careful consideration of our leading writers on physical science. A reform is obviously needed. They alone can carry it out.—*Engineering.*

AN IMPROVISED HYDROGEN GENERATOR.

ALMOST every laboratory makes certain modifications or adaptations of well-known pieces of apparatus, formulæ, and methods, such changes being often convenient for conditions under which they are applied. Very often these changes would not be improvements under other conditions, and not uncommonly the individual who devised them regards the changes trifling in character, and presumes that, of course, someone else has similarly applied the idea involved, and that it might be presumptuous on his part to publish so simple a thing. The pieces of apparatus to be described, we have no doubt, have been utilised by other workers, in one form or another, but we are unfamiliar with any publication which has been made on the subject.

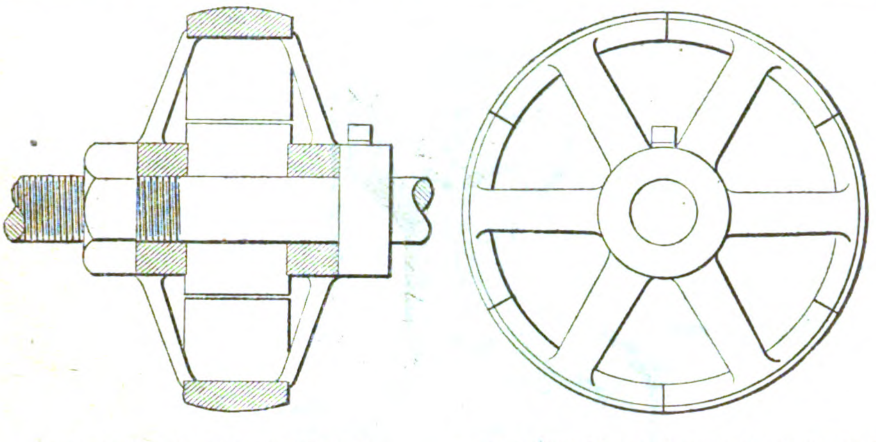
During the progress of some work on the bacillus of tetanus there was constant need of a hydrogen generator, which could be thoroughly controlled, and at the same time one which could be depended upon, under all conditions, to afford sufficient hydrogen for any anaërobic apparatus in use. Of the many forms of hydrogen generator, none seemed at the time available, and so the apparatus shown in Fig. 1 was, after some experiment, devised by Dr. Coplin. It can be constructed anywhere, and under almost all conditions. All that is needed is a bottle, preferably a salt mouth bottle of from 8oz. to 16oz. capacity (bottle shown at B in illustration). A stopper with perforation, or corrugated at the side by cutting out pieces, is a convenience, but not a necessity. Such a stopper may be of cork or wood, or, what is best, of rubber. It should fit with sufficient tightness to prevent the submerged bottle from coming loose, spilling the zinc, and rising as a result of the buoyancy of the contained gas. A glass or rubber tube (such as shown in the illustration at D) is passed through a hole in the cork so that the end within the bottle reaches to the bottom of the bottle, B; the length of the projecting end of the tube will depend upon the depth of the outside container, and the distance to which it will be desired to conduct the gas to other apparatus. It is best to make this tube of glass, although rubber tubing will do; where fragility is an objection, lead might be substituted, although the authors have never used anything but glass. The conducting-tube D should have an internal diameter of ·5cm. to 1cm., and should be sufficiently heavy not to break easily. The outside container, A, may be a wooden bucket, crockery jar, ordinary battery-jar, or Whitall-Tatum museum jar, with a perforation in the lid through which the tube can be passed; a large-sized Millville gas-jar, such as made by Whitall-Tatum, will be found most convenient. We used such a jar for some time, but it was accidentally broken, and since that time we have used an ordinary museum jar; when the apparatus is not in use we lift out the bottle containing the zinc and set it to one side, and stopper the jar containing the sulphuric acid. To use the apparatus, a sufficient quantity of scrap zinc, or zinc turnings is placed in the bottle, B, the bottle is then laid upon its side, to permit of the insertion of the tube and stopper. The bottle is now turned upside down, as in the illustration, and inserted into the



A, container filled with sulphuric acid up to the level shown; B, 8oz. to 16oz. bottle turned upside down, and closed by perforated stopper shown at C. Through this perforated stopper passes the short arm of the conducting-tube D. It will be observed that the end of the tube within the bottle B extends above the acid level. Just below the large drawing is an end view of the stopper, showing perforations, and the conducting-tube D passing through the stopper. The horizontal arm of the conducting-tube D is connected with a large piece of rubber tubing, E, and the flow of gas controlled by a Mohr's pinch-cock, F. Any piece of apparatus may be connected to the rubber tubing at *a*. If the connecting-tube D be bent in the shape of an S at the point where the letter D is shown, this S may be hooked over the top of the container to hold the bottle B out of the fluid when not in use.

diluted sulphuric acid in the outside container. The height of the liquid in the outside container should be so adjusted that when the bottle containing the zinc is pushed down as far in the sulphuric acid as it will go (and the acid permitted to rise to its own level within the bottle containing the zinc), the acid will not come nearer than 2cm. of the end of the tube within the bottle B. The object of this precaution is, of course, apparent. Should the acid be admitted sufficiently near the bottom of the bottle (which is now the top) it would run over into the tube and form a trap at the bottom; or if the tube is small, it might be carried on into the apparatus with which the tube is connected. At the external end of the tube a piece of thick rubber tubing, E, is attached, and a Mohr's pinch-cock, F, is adjusted so as to collapse it. The rubber tubing may be attached to anaërobic culture apparatus of any kind, or to any other piece of apparatus which it may be desired to use. If, at any time, the exit of the gas from the tube be prevented, the acid is forced away from the zinc by the continued generation of gas, and in a very short time chemic action is arrested. The apparatus may may be used for the generation of sulphuretted hydrogen, or, with slight modification, of carbon-dioxide, &c.

The points which have recommended the apparatus to us are:—(1) Its simplicity; (2) its cheapness; (3) any student can make such an apparatus from materials always available; (4) it may, by some of the suggestions already given, be kept practically always ready for use; (5) it is not easily broken, and all the parts may be replaced quickly and cheaply; (6) it is efficient.—*Journal of Applied Microscopy*, N.Y.



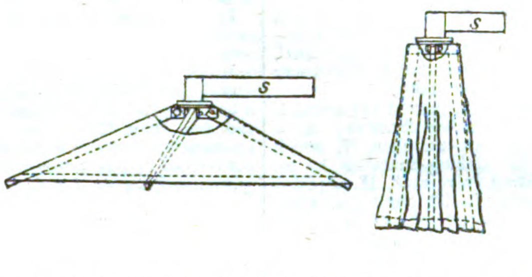
AN EXPANSION PULLEY.

THE accompanying sketch is that of an expansion pulley designed by Mr. Florence, master mechanic of the Newnan Cotton Mills. This special pulley was designed for a yarn winding-machine, and was to regulate the speed of the traverse which guided the lay of the yarn on the ball. It was desired to lay the yarn side by side, with no space between, so fine yarns had to be laid closer than coarse yarns. It was thus necessary to change the speed of the traverse, and it was found that the change from the finest to the coarsest yarn to be wound only required a variation in diameter of a 6in. pulley of less than $\frac{3}{100}$ths of an inch, so it was impossible to get change-gears to make the difference, and cone-pulleys would not give satisfactory results; so this very simple, and yet very efficient, pulley was designed.

It will be seen from the sketch that the pulley consists of two sets of spokes connected to a common rim, but to different hubs. The rim is cut midway between each set of spokes, so that when the two hubs are compressed together by means of the nut on the shaft upon which they are mounted, the rim will be forced out. The spring in cast iron was found to be sufficient to give ample variation in the size of the pulley.—JIB, in *American Machinist*.

COLLAPSIBLE PROPELLERS OR PADDLES.

THE invention patented by Mr. A. R. Upward, of London, relates to "collapsible" propellers adapted to be reciprocated under water for the propulsion of light craft. It may be of interest to some readers, for the idea has been put forward in various shapes. In the present form (No. 20,269, 1898) the patentee describes the apparatus shown,



which is adapted for attachment to the end of a pole (a punt pole for example) when it is desired to navigate in deep water. The pole is alternately used with a backwards and forwards motion, and is attached by a hinged joint to the rod S, which passes through bearing blocks on a travelling guide, in which blocks the rod turns, thus providing for steering by allowing the propeller to be set or thrust through the water at any angle which may be given to the pole.

LONG AND SHORT-DISTANCE PROJECTION LANTERNS.

IT will be manifest that an instrument more especially designed for use in a private dwelling-house would be practically of little utility for projection purposes in large halls or theatres. Therefore, in the selection or purchase of a lantern, it is important that some consideration be bestowed upon the special purposes for which such lantern will ultimately be required. In the event of a lantern being desired for home use only, the optical arrangements will differ materially from such as would be required in a lantern designed more particularly for long-distance projection.

In the latter, not only are long-focus objectives required, but the condensers to converge the pencils or rays of light passing from the lime ball through the picture or slide must also be of longer focus than would be the case were an objective employed for moderately short-distance working. It is just here where much misconception exists among amateur lanternists, the belief being very general that all that is necessary to to adapt any well-constructed lantern for the use at varying distances from the screen is the substitution of long or short-focus objectives in proportion to the distance it is desired to work from, whilst the equally important bearing which the candenser plays in such projection is entirely overlooked, for a condenser that yields admirable results in converging rays of light when employed in conjunction with a five or 6in. objective will fail to give anything like results in connection with, say, an objective of 12in. focus.

Nearly all the trade or stock lanterns supplied by even our best opticians are fitted with what may be termed short-focus condensers and short-focus objectives, the idea, doubtless, being to adapt same more particularly for short-distance working, such as would be required in dwelling-houses, where the aim is to obtain the largest possible size of picture within the shortest distance from the screen. Such lanterns will be found in all likelihood, to be fitted with double plano forms of condensers of about 4in. focus when measured from the centre of the combinations, or 3in. from the back lens to the lime ball when the jet is finally adjusted in its proper position for focussing the light upon the screen, with the aid of, say, a 5in. or 6in. objective.

Now, there is really no difficulty in converging all the rays of light from a spot of, say, $\frac{3}{4}$in. (such as an ordinary lime cylinder yields with a good mixing jet at fairly high pressure) at a distance of 6in. in front of the condenser, and such an optical arrangement will be found to work admirably, but the moment we come to change the 6in. objective for one of much longer focus—say, 12in. or more—we introduce a radical change in the whole optical arrangements of the lantern. The jet which has hitherto been placed in its best position for the convergence of the rays at a distance of 6in. in advance of the condenser will require to be placed considerably nearer the back lens of the condenser to converge the light at a greater distance than 6in. in advance, and, as we have seen already, that to gain the necessary amount of convergence with the short-focus condenser that is being employed, a distance of only 3in. is available as an angle of incidence for the rays to spread over the face of the condenser, not only would the jet or lime ball be too near the back lens of the condenser, and hence very liable to fracture the same, but the corners of the picture would be improperly lighted. It therefore follows that, if we are to use long-focus objectives, we must provide suitable condensers, in order to so converge the light that they may be employed to their best advantage, and this is a most important point when selecting a lantern for long-distance projection. Strange to say, many of our salesmen with opticians, and who are supposed to be expert in lantern matters, are seldom found possessing a knowledge of this fact.

Another important matter in connection with long-distance projection is the diameter of the back lens of the objective. In short-focus lenses, say, of about 5in. to 6in., the diameter of the back lenses is generally found to be about $1\frac{5}{8}$in. Now, with short-focus condensers, it is quite easy to converge all the rays from a lime ball into a cone of such diameter at a distance of 6in. in front of the condenser; but the moment we attempt to converge the rays into a similar cone at varying distances in advance, so soon do we find our difficulties beginning, and a point is soon reached when lenses of the diameter above stated—viz., $1\frac{5}{8}$in.—will fail to grasp or pick up all the rays transmitted by the condenser. At this point such an objective will begin to lose light, and therefore, with the longer focus objectives, there must be provided larger diameter of objectives. Up to 8in. or 9in. in front of the condenser, objectives of $2\frac{1}{4}$in. will be found ample; but when much longer-focus lenses are employed as objectives, then their diameters must likewise be increased, and every aid rendered by the employment of suitable longer-focus condensers.

In the early days of the limelight, when we had nothing like the pressure we have at present from gas cylinders, the practice of working so as to project as large a disc as possible from a short distance was quite a necessity so as to get the utmost amount of illumination, and no doubt this old practice has done much to foster short-distance projection even in the present day; but limelight procedure is quite a different matter now to what it was 25 years ago. Compressed gas has enabled improved jets being employed, and now, with suitable apparatus, it is possible to project a picture in a brilliant manner which at that early period was practically impossible.

The advantages of long-distance projection over short-distance working are many, not the least of them being the comfort to an audience provided by their having no interruption in the form of the emission of light from the lantern placed in advance of them.

Speaking generally, but few schoolrooms or country halls will be met with that do not contain a floor space of at least 50ft., and, whenever such have to be used for lantern entertainments or lectures, there is no better size of screen to employ than one of 12ft. or thereabouts, and to use a 12in. objective at a distance of about 45ft., which will yield a suitably sized picture on the 12ft. sheet.

By working from the back of the audience, an operator can always depend upon less interruption than is the case when he finds himself surrounded and cramped by numerous inquisitive onlookers; and, further, he is enabled to take more licenses with the doors and ventilator of his lamp than is possible when working in front of the audience.

As to brilliancy of light, if a good mixing jet be employed, there need be no anxiety; of course, the same results are not obtainable with a blow-through, but, then, no operator of experience nowadays ever thinks of employing such in long-distance projection. A well-packed mixing jet with a bore of $\frac{1}{20}$in. or $\frac{1}{25}$in. will yield all that is required in the way of light, and at the same time not overheat the lamp, as larger bores are very liable to do.

During recent years there has been a distinct movement on the part of lantern-makers to reduce the size of the shells in both the single and double forms of lanterns, until it is safe to assert that the thing has been ridiculously overdone. There may, indeed, be no need for such clumsy shells as were in vogue some thirty years ago; but a lantern of good size will work much cooler than some of the small-sized articles now so prominently on the market, and it by no means follows that for single-lantern projection wooden-lined bodies should be employed—these wooden bodies keep in the heat that would otherwise escape; a metal body will work cooler than a wooden-lined one, in so far as being less destructive to condensers.

The theory that light is lost by using long-focus condensers may be entirely discarded; any loss of light arising from the jet being drawn further back when long-focus condensers are employed is fully compensated for by the better class of jets now in use, and they are easily pushed to a greater extent without hissing than was formerly the case.—T. N. ARMSTRONG, in *British Journal of Photography*.

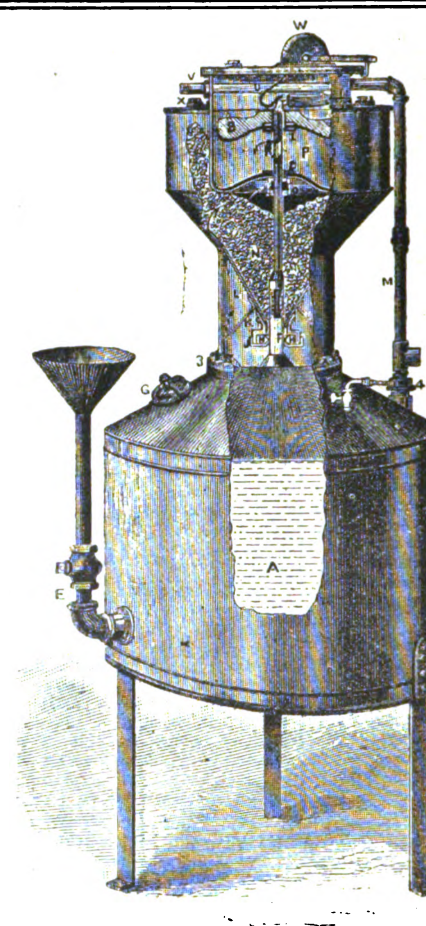
COLOUR PHOTOGRAPHY.

AT a meeting of the Columbia Photographic Society, Philadelphia, the editor of the *Camera*, assisted by Mr. P. A. Mitchell, gave a demonstration on "Colour Photography by the McDonough Process." Over fifty slides (made by the process) were shown, and the manner of making the exposures, &c., was demonstrated. The following extracts from Mr. Chambers's lecture may be of interest:—Colour photography, which has been much in experiment in this country and abroad for years past, has now practically reached a state of perfection. Few of us realise the difficulties encountered by the inventors of the processes on the market, and the most simple, the one easiest understood by the amateur, is the one we here demon-

strate this evening, the McDonough process. The expense in using this is very small, the cost of fitting up a camera but a trifle, and the results gratifying. The method of photographing colour by this process is on the scientific principle of the mixed coloured light. Many scientists have demonstrated that the elementary or primary colours of a ray of sunlight are red, green, and blue, and the mixture of these on the retina of the eye produces the colour sensation of white, and all the various shades of colour are the resultant of these three fundamental sensations. In the McDonough process the essentials employed for making a negative are a "taking screen," "chromatic balance shutter," and erythro dry-plates, the latter being the Seed 26 x normal plate orthochromatised for the red wave-lengths of light. The "taking screen" is a plate of glass coated with gelatine emulsion and ruled in red, green, and blue parallel lines from 300 to 600 to each inch, in the order named. This "taking screen" is adjusted in a metal frame inside the camera, and attached to a lever conveniently placed outside the box, where it can be used to throw the "taking screen" in contact with the erythro dry-plate when slide of plate-holder is withdrawn to make exposure. The "chromatic balance shutter," which is placed on hood of lens, is made with sectors of lemon-yellow and orange-coloured glass or mica, actuated by a metal finger, and its office is to balance the varying conditions of illumination, there being less blue in bright sunlight than with cloudy skies or when photographing indoors. The adjustment of the shutter for the difference in illumination is by moving the metal finger to open or close the coloured sectors. A negative made under conditions noted will show in duplicate the lines of the "taking screen," but with different degrees of opacity according to the light value that has fallen upon the silver haloids of the sensitised erythro dry-plate through the "taking screen" and "chromatic balance shutter." Their colour-value lines are transferred to the positive, which is made in the ordinary manner, by superposition, using any good transparency dry-plate, and the transparency or positive so obtained is placed in contact with a "viewing screen," which is made exactly like the "taking screen," only on thinner glass, the red, green, and blue lines corresponding in number to those used on the "taking screen," and the lines on positive or transparency and "viewing screen" being in parallel or register, the colour appears as in the object photographed. When this is done, fasten the two together with spring clips, bind the edges with adhesive strips, and the positive is ready for the window or projection in the lantern.

Several things are peculiar to the McDonough process regarding the matter of development. There is no choice as regards a certain developer being used—any kind may be employed; the only thing is that it is necessary to use it slightly weaker, and with reduced quantity of alkali; that is to say, if you were to use a developer requiring 4oz. of water, you would add 50 per cent. more, making it 6oz. Then, if the completed mixture would make, say, from 8fl.oz. to 10fl oz. of developer, we add ½oz. of a 10 per cent. solution potassium bromide; we do this owing to the extreme sensitiveness of the plate, and in order to prevent fog from over-exposure and development. I might say that, in all my experiments with the process, I have not had one fogged plate in my developing, and, in cases where I have deliberately over-exposed, I have been able to control it, and secure a perfect negative by the use of my bromide. The erythro plate employed is extremely sensitive to the red light in the dark room; my plates were developed in practical darkness, and after two tests I found that I could employ time developments and secure absolutely perfect results. The other evening I purposely tested one of these plates under the red light; one-third of the plate was covered, and the other two-thirds developed with the red light shining upon it. The result is that two-thirds of the plate exposed to the red light is most beautifully fogged. The one-third of the plate which was partly shielded does not show this trouble. In my method of exposure I found a Wynne meter a great boon; in fact, I should have been totally at sea without its aid at first, as these plates require a more lengthy exposure than the normal Seed's 26 x, owing to their special preparation. The International Colour-Photo Company, of Chicago, to whom I am indebted for the manner and form of testing this process, furnished me with a formula for developing my transparency plates. I not only find this excellent for my work with the colour-process transparencies, but it is also fine for ordinary slides.

I will give it to you:—Water 24oz., hydroquinone 180 grains, sulphite of soda (crystals) 5½oz., formaldehyde (40 per cent.) 3 drachms. This is the stock solution. For use, to the 4oz. of the stock solution add 2 drachms of 10 per cent. bromide of potassium. This may strike you as rather peculiar, as no alkali is mentioned in the shape of soda or potash; but the formaldehyde fills all the requirements of an alkali, and it also prevents shrinkage in the films.



THE "BECKLIGHT" ACETYLENE-GAS GENERATOR.

FEW industries have experienced a growth so rapid as the manufacture of acetylene-gas generators. When the production of calcium carbide was made a commercial possibility by the Willson process, a host of machines sprang up, which, as in most early forms of apparatus, were crude in construction and often wrong in principle. Gradually manufacturers began to investigate and apply the principles which should govern acetylene generation, and which would insure the safe and cheap production of the new illuminant. Of the many forms of apparatus constructed with a view of meeting these requirements, we may mention a machine made by the Acetylene Generator Manufacturing Company, of 106, Bell Block, Cincinnati, Ohio, a machine which is the result of no little study on the part of the inventor and makers.

The "Becklight," as the improved apparatus is termed, consists of a slaking-chamber, A, a gasometer, P, and a carbide-chamber, N, which communicates with the slaking-chamber by an opening having a yielding valve-seat, H, adjusted in position by a screw-cap, J. Through the valve-seat H a feed-plunger, F, passes, which is connected with an elbow, T, secured to a connection, U, for the gas-outlet. The carbide feed is locked by means of a lever and sheave connected with the elbow and contained in a housing, W. The stem of the feed-plunger F is provided with four indentations for feeding carbide, and with a passage, R, to conduct gas to the service-pipes. At the lower end of the carbide-chamber, a condensing-chamber, K, is arranged, which also provides a drying space, L, through which the gas passes upwardly. To force the gas through the pipes and regulate its pressure, a counterpoise, S, is secured to a gas-bag.

In operating the machine, the gas is first shut off from the service pipes and the lever operated to lock the feed mechanism. After the residue is removed from the water-chamber, water is introduced. The generator is then entirely closed by shutting the various valves, and carbide is introduced by removing the plugs X. After releasing the feed-mechanism by means of the lever and sheave, the generator begins to work by pressing gas out of the gasometer, thus lowering the feed stem, so that its indented portion passes the valve-seat H. An opening being formed, the carbide drops in a circle to the water below. The pressure of the resulting gas naturally seeks the point of least resistance, which is that side of the gasometer exposed to the atmosphere. The gas, therefore, passes up first against the condensing surface K, depositing its moisture on the cold surface, then through the reduced inlet between the lower edge of the surface K and the outside generator wall, into the drying space L, thence into the carbide-chamber, as shown by the arrows, through or over the carbide, whereby it is both screened and dried, into the passage of the stuffing-box O, and finally through the passage R, the hollow elbow T, and the connection U into the service-pipe V. If the consumption fall off, the inflated gasometer forms a cushion for the weight S, thus locking the feed-mechanism until the amount of gas in the gasometer P is reduced.

The weight, feed-stem, and gas-bag being integral, no gas can possibly pass into the gasometer without at once closing the feed-opening. The gas is resisted by the weight S, and when the pressure is excessive the weight is raised.

It will be seen from our illustration that the carbide and slaking-chambers are so arranged with respect to each other that the apparatus is far more compact than most others of the same class. The carbide is fed into the water in small quantities, for it has been found that the gas thus generated is cool and free from the dangerous benzine and other hydrocarbon vapours which always accompany the gas formed by generators operating on the dripping system.—*Scientific American.*

A FEW FACTS ABOUT LYDDITE AND CORDITE.

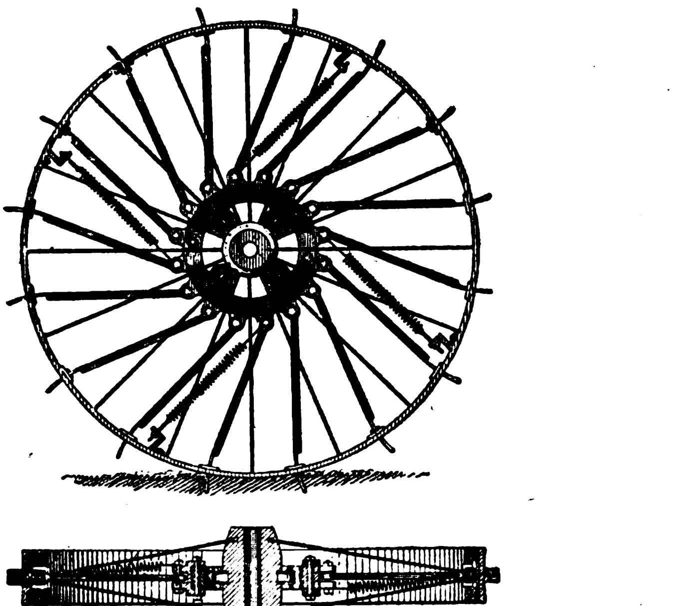
LYDDITE, the latest and most powerful of artillery explosives (for references apply to General Joubert, says the *Daily Mail*), takes its name from the little town of Lydd, near Hythe, where it was first manufactured. Picric acid is the base, with certain proportions of sulphuric and nitric acids, the secret being known only to the British Government.

When in the crystallised state lyddite resembles powdered sulphur in appearance. Its explosive force is terrific. At Omdurman, where it was first used in warfare, by the impact of its explosion—not by the fragments of shell—it blew men and fortifications to pieces. Lyddite is largely used by dyers [?].

Of other explosives, cordite is in origin and composition akin to the familiar dynamite or "giant powder." It is prepared from gun-cotton and nitro-glycerine.

Gun-cotton is cotton-wool or other cotton fabric treated with a mixture of three parts of sulphuric acid to one of nitric acid. This was discovered by a chemist named Schonbein in 1846, but its manufacture and use were surrounded with great danger and disaster, until Sir Frederick Abel perfected the method of making it in 1863.

Cordite is made at the Government factory, Waltham Abbey. To 27¾lb. of gun-cotton is added



43½lb. of nitro-glycerine, and these compounded in a brass-lined box become cordite paste. It is transferred to a kneading-trough, and for three hours and a half thoroughly mixed and incorporated with 15lb. 10oz. of acetone. Vaseline to the amount of 3½lb. is added, and after a further three hours' manipulation the cordite dough is ready.

Placed in a cylinder, it is pressed out in a thin string and wound round a drum. From its resemblance to string or cord comes its name of "cordite." The reels on which it is wound are dried, and the cordite, cut into required lengths, is ready for its deadly work.

It can be handled with perfect safety; lighted and burned in the hand. It consumes itself slowly with a yellow flame. It is only when burning in the confinement of a gun-barrel that it becomes explosive, the gases then generated occupying a volume a thousand times greater than when burned in the open.

Seventy grains of black gunpowder fired from a rifle give a muzzle velocity of 1,350ft. a second. Thirty grains of cordite give a muzzle velocity of 2,000ft. In cannon 1lb. of cordite gives a greater velocity than 5lb. of gunpowder. It is smokeless, and does not foul the gun, though apt to corrode it if the barrel is not carefully cleaned. It is rather sensitive to changes of temperature, and if kept a very long time, loses some of its power.

BIRD SENTINELS.

THE following notes, by Mr. F. G. Aflalo, in the *Morning Leader*, are interesting:—*Le Chenil*, which is the weekly publication of the Paris Acclimatisation Gardens, has just given a most interesting article on sentinel birds, in which, besides enumerating the various cattle and rhinoceros birds, some warning even the lion, while a species of cuckoo watches over the fortunes of the ratel, assigns the same duties to the well-known crocodile bird. Now, I thought all the skill of travellers had been exhausted in supplying fiction about this little lapwing, where fact failed to do all that was required of it; but I did *not* know that it was in the habit of warning the crocodile of the approach of man. And I venture to doubt it for two reasons. In the first place, I have passed crocodiles about which all manner of birds were running (and no doubt this same spur-winged gentleman among them), and on no occasion that I remember did they slide off into deep water at my approach. My second reason is, perhaps, even more valid than this. The fact is, crocodiles have not, at least among the natives of these parts, enemies enough among mankind to make it worth while for nature to have specialised a bird for that sentry work. I am quite ready to give the crocodile its due as a scavenger, and to regard it as fully worth preserving for its services; but, until the white man came on the scene with his rifle (in his last book Mr. Kirby tells of a lucky shot that killed a crocodile with a *rook-rifle!*) there would have been simply nothing for the lapwing to do, and it has certainly not learnt its new duties in the course of a century.

Two additional steam turbines at the Halifax Corporation electric-power station have been started. It is intended to use them for the tramway service. The enlarged premises will give accommodation for machinery equal to 25,000H.P., in place of the existing 2,500H.P.

A CURIOUS TRACTION-WHEEL.

THE traction-wheel shown in the annexed engravings is rather a curiosity, and we reproduce it from the *Scientific American*, but whether it is patented or not is not stated. It is thus described:—The traction-wheel which we illustrate is the invention of Clarence Grosseclose, of Sylvia, Kan., and is particularly adapted for traction-engines, automobiles, and harvesting-engines. Surrounding the hub of the wheel is a ring carrying rollers which bear upon the bottom of a groove formed in the hub. Arms pivoted to lugs on the outer side of the ring extend outward tangentially to the ring, and carry at their free ends blades which project through openings in the rim, and which adapt themselves to the nature of the ground —hard or soft—over which the wheel must travel. Some of the blades are provided with stop-pins passing through holes in the arms; the blades are thereby prevented from moving too far outward. Springs are connected at their inner ends to the ring, and are adjustably secured at their outer ends to brackets on the rim.

Should the wheel travel over hard ground or bridges, the blades, as they engage the ground or floor, will be forced inwards, causing the ring to rotate on its bearing-rollers. Upon reaching soft ground the blades will be moved outwards by means of the springs, acting upon the ring, so that they will engage in the ground. By arranging the arms at a tangent, the bearings formed upon the ring will be at one side of its vertical centre line, thus insuring the rotary movement of the ring mentioned.

PIN-POINT JOINTS.

EXPERIENCED fretworkers will readily agree with the observation that the work of fixing up articles is usually more difficult than cutting out the pattern. Beginners rarely realise this, and the result is that, while their sawing may be accurate, their preliminary attempts in the cabinet-making line are far from brilliant. This is partly due to want of practice in the handling of tools, but it is also largely due to a very childish desire to see the article completed before it is properly begun. This is why we often see pieces of fretwork which betray the neglect of sandpaper, and reveal the clumsiness of the amateur's fingers. The finished article may indeed be strong, but in fretwork, unless strength and neatness go hand in hand, the work can never look attractive.

For small articles, where delicate fixing is required, ordinary household pins may be employed to considerable advantage. The points should be cut off with a pair of wire-cutters, about ¼in. or ⅜in. from the end, and these used instead of nails. Over nails and screws they have a double advantage; being headless, they are almost invisible when driven in, and as they are practically as fine as needle points there is rarely any danger of splitting the wood. Of course, pin-points in themselves cannot be expected to give a strong hold, but used along with glue they are very serviceable.

As pins will bend if they are driven in with a hammer, it is better to hold them with a small pair of pliers and press the points into the wood. A gentle rub with sandpaper is usually sufficient to hide any trace of the broken head. With white woods, such as sycamore and holly, it is better to adopt a different plan. When, for example, a bracket support is to be fixed to a shelf, and where it may not be desirable to drive the pin-point right through the latter, the point of the pin should be held in the pliers, and the blunt end forced into the wood. The other piece is then pressed against the sharp point, which has been allowed to project about an eighth of an inch, and the two parts thus joined. This is merely an example suggested to show the principle.

The chief value of such a method is felt when overlay ornaments are being mounted. The difficulty of fixing these neatly is often experienced, even by advanced workers, who find that the applied ornament is apt to start if exposed to the sun or placed near a fire. If a few pin-points are fixed in the background, and the glued overlay then pressed on to these, the hold of the pin will usually be sufficient to prevent the glue from giving way.—*Hobbies.*

BALLOONS IN SOUTH AFRICA.

THE question has been raised whether advantage cannot be taken of Marconi's system to use balloons as actual engines of war, and whether decisive results could not be obtained by their use. Doubtless there is in this case, as in most branches of work, a certain amount of information which is jealously guarded as confidential, but we believe (the *Engineer*) that it would be found chiefly to refer to methods of application and practical details which hardly affect the broad question as to the power at our disposal, which is no doubt sufficiently startling and suggestive. Expressed in popular language, we have by the application of wireless telegraphy the power to drop and fire an explosive at a great distance, say, ten miles off. This may be carried out in the following way:—A free balloon may be charged with the explosive, and with gear for releasing it and firing it. It may, for example, take the form of a shell charged with high-explosive and with a percussion fuse. The sensitive apparatus which responds to the electric discharge at the directing point is also set up in the balloon, and with a suitable wind this balloon is set free, no living occupant being in it. Its position may be followed by observers stationed at the extremities of a sufficiently long base line to give some measure of accuracy, and on the signal being given the shell is released. This sounds formidable enough; there are, however, various difficulties and objections. First, it is very difficult, perhaps impossible, to cause the balloon to travel exactly over the desired spot. If the directing or starting-point is ten miles off, it may be questioned if the balloon would ever travel over a desired mark of small area; and if the mark is of large area, it may be questioned what good would be effected by it. We know, in fact, that it has been deliberately laid down by high authorities that, in the attack of a fortress, all shells are wasted which do not strike an actual gun or a magazine. This must, no doubt, be subject to some modification; but it is generally true that the useful targets are very small objects, such as it would be hopeless to get a free balloon plumb overhead from a distance approaching ten miles. Thus the balloon attack would resolve itself into one of general bombardment. This is open to grave objection. It generally means a useless destruction of life and property, for rarely indeed has any reasonably strong place been captured by such means. Further, at the Hague Conference, if we remember rightly, this particular form of attack was one given as an example of brutal, unpermissible warfare. For purposes of conflagration, it might be effectual. Even at very great range a town might be set on fire; but the gain is questionable, and under most circumstances would be an unjustifiable act, and one which would provoke the condemnation of civilised nations. At a comparatively short range, probably a more definite and less general blow might be struck; but the question then arises whether it would be as effectual as shell fire. A much larger charge of explosive might probably be employed; but a charge out of proportion to the case or shell which it bursts may effect very little. A 6in. gun discharges a projectile of 80lb. or 100lb. weight; a 4.7in. gun, of 45lb. weight. Thus a balloon load is soon made up with the weight of shell and other necessary gear. The strong point in favour of such attack is that the shell having no onward velocity is specially adapted for searching behind cover which is difficult to reach with high angle fire, and impossible with shrapnel, from ordinary field guns. There are circumstances probably, then, when something might be done by balloon attack of this kind; but whether it would be considered legitimate warfare is doubtful. Probably many of our readers may think with us that it may be better to employ balloons in the unquestionably valuable work of observation and direction by signals from captive balloons, which have already performed most important functions in discovering the position of guns whose smokeless discharge renders it peculiarly difficult to locate them. A somewhat similar case may be found in the adoption of the dynamite gun fired from the United States vessel *Vesuvius*. The shell of this

gun had appalling explosive power. The gun was employed in the attack of Cuba; but the total failure in accurate direction so discredited the gun that its development during three or four years ended in complete disappointment.

DO ANIMALS FEEL PAIN LESS THAN MEN?

WHAT we call "an ear for music" is almost an added sense in some people as compared with others. Even in animals of relatively high intelligence, such as dogs and monkeys, there seems to be reason to think their perception of pain is much less acute than in humans. After serious operations under chloroform they are often frisking about a few minutes after recovering consciousness, and even jumping from the floor on to the operating-table in a way which forbids the notion that they are then suffering. In all animals the skin is probably less sensitive than the human skin is. It is covered with insensitive hair, and though, no doubt, more sensitive than any other part of the body, it is presumably on a quite different plane of sensitiveness to the human skin. In human beings the sensitiveness of the internal organs is very small as compared with that of the skin. Examples of this are familiar to everyone While in health no one knows anything of his "inside"; he has no sensations from it. Even disease of a very serious kind can, and often does, go on for years in the internal organs without causing any sensation. The nerves of the internal organs are much more concerned with regulating functions, and controlling the size of the blood-vessels, than with the conveyance of sensory impressions to the brain. Life would, in fact, be unbearable, if the functions in of animal life in a normal condition caused sensation, and they would cause it if the organs were richly supplied with sensory nerves. Every surgeon knows, for example, that the human intestine is, when its muscular coat is at rest, almost as insensitive as the hair or nails. In the operation of opening the intestine, often required in the presence of malignant disease, the cut in the skin and the business of fixing the gut to the skin would be very painful, and deep anæsthesia is required. Two days later, when the gut in its new position has to be opened, the patient is told to shut his eyes, and he feels nothing—he does not even wince—while a wound nearly two inches long is made in the intestinal wall with either knife or hot iron. This has been proved by many hundreds of cases, and certainly it is not to be explained as due to stoicism on the part of the patient. Other important operations have been done without anæsthesia except for the skin cut, and without giving rise to suffering of at all a severe kind. It is most improbable that even the highest of the lower animals would feel pain where man feels none. On the contrary, from their smaller brain development, they probably always are less sensitive than man.—*Edinburgh Review.*

A RAIL-JOINT hydraulic press is being introduced in America for the purpose of driving the splice bars home to a good bearing on the rail while the bolts are being put in, thus preventing trouble from the lack of tightness in new joints. The machine is especially intended for the deep heavy splice bars of street railway girder rails, some of which have twelve bolts, in two rows.

The Last Memorials of Lunar Life.—Some suggestions as to the cause of the dark areas on the moon, the so-called "seas," are given in the November issue of *Knowledge*, by Mr. J. G. O. Tepper. Referring to our satellite as a dying world, the writer says:—With the diminution of the water, and the atmospheric gases, the decay (disintegration) of dying organisms would be at first more and more delayed until all were dead besides the *mould* of the soil, the last memorials of organic life. . . . Since the total disappearance of the atmosphere no currents can possibly exist, and the finest, lightest dust must remain eternally undisturbed, except by the rude shock of a colliding meteor, or when ploughed aside by such, if gliding along after a very oblique impact. It is well known that there is no body more absorptive of light than finely-divided carbon particles, hence their intensely black aspect. At the same time, dust, or loosely-cohering matter, reflects little light, except at very oblique angles of incidence. In the 'seas' of the moon we may, therefore, have large areas covered by carbonaceous dust, the last remains and the last evidence of the former vegetable and animal organisms of our satellite, for the one class cannot possibly exist without the other, unless in the lowest forms, known as Protozoa and Protophyta (i.e., the the same organism discharging the function of both, in absorbing carbon and nitrogen exclusively). As an hypothesis the above appears to me to fulfil most, if (perhaps) not all, the conditions demanded in the works perused by me, and I shall be glad to learn wherein it fails.

SCIENTIFIC SOCIETIES.

BRITISH ASTRONOMICAL ASSOCIATION.

THE first ordinary meeting of the tenth session of the British Astronomical Association was held on Wednesday, Nov. 29, at Sion College, Thames Embankment, Mr. W. H. Maw, F.R.A.S., the President, in the chair.

The President said that before the regular business was proceeded with he had an announcement to make, and he did so with much regret. Since the previous meeting they had lost, by death, their late President, Mr. N. E. Green. As many present doubtless knew, Mr. Green was one of the founders of this Association; he had served on the council as vice-president, as director of the Saturn Section, and was his (Mr. Maw's) immediate predecessor in the chair. In all these offices he fulfilled his duties in a most conscientious manner, and not only so, but he fulfilled them with an unfailing courtesy which endeared him to them all. As an astronomer, Mr. Green was a representative of the very best type of amateur observer. He never sought to make sensational discoveries, but he was a keen and accurate observer, and recorded all his observations with the utmost care, and with the greatest skill. His training as an artist enabled him to do this in a way with which the members of this Association were well acquainted. It would, he (the President) thought, be admitted that Mr. Green's planetary drawings had become classic. He had had an opportunity himself of examining many of the originals, and could say without hesitation that none of the reproductions in any way did justice to the beauty of the original work. For fidelity to detail and delicate rendering of colours and shading, these drawings had rarely been equalled —they certainly had never been surpassed. At the council meeting that afternoon a resolution was passed containing a vote of condolence to Mrs. Green and her family. It read as follows:—"The council and members of the British Astronomical Association had learned, with the greatest regret, of the death of Mr. Nathaniel E. Green, formerly president of the Association, and director of the Saturn section, and they desire to express their deep sense of the loss which the Association and astronomy have sustained thereby, and to offer their sincere sympathy to his widow and family in their bereavement." In order that the members of the Association generally might join in the vote, it was proposed to add the words "and members" after the word "council," and he would therefore put to the meeting a resolution that such addition should be made.

The resolution was passed unanimously.

The names of eight candidates for membership were passed for suspension, and the election by the council of 15 new members was confirmed.

An interim report on the Meteoric section, dealing with the November Leonids of 1899, was first presented. The director, Mr. W. F. Denning, announced the receipt of a large number of reports of this shower from observers in various parts of the country. These reports were from both members and non members of the section, and testified to the widespread interest awakened in the event and to the earnest efforts made to witness it. But there was a general failure. The meteors did not appear in the numbers expected; in fact, the display was not more rich than an ordinary shower of the August Perseids. The comparatively negative results were due to several circumstances. Primarily, no doubt, the cause was that the earth traversed a tenuous region of the swarm in front of the denser part, which gave rise to the brilliant displays in 1833 and 1866. At many places the weather was very unfavourable; there was bright moonlight except for a brief interval, and quite possibly the shower was at its best during daytime in England. But from telegraphic reports in the newspapers it would appear that the phenomenon similarly disappointed observers in other countries. No intelligence had yet come to hand of a really brilliant display in any part of the world. The observations of the recent shower were somewhat at variance in regard to several of the more important features, but they led to the following conclusions:—(1) The duration of the shower was from Nov. 8 to Nov. 18 inclusive; (2) the maximum occurred on Nov. 14 in the hour between 17h. and 18h., when, however, not more than 25 Leonids were visible to one observer; (3) the radiant point was at $151\frac{1}{2}° + 22°$; (4) the radiant was probably a fixed position according to the paths of several early Leonids, but the evidence they afforded was perhaps not conclusive. One of the finest meteors observed was that seen by Sir W. J. Herschel, at Littlemore, near Oxford, on Nov. 14, 17h. 40m. It left a streak for 5 min. It was also recorded by several undergraduates at Jesus Coll., Oxford, who described it as large and very brilliant, and leaving a train for 3 minutes. The same meteor was observed in other parts of the country.

Dr. Johnstone Stoney said that while we have to regret the absence of the great Leonid display for which we had hoped, it is some consolation that the risk of what has actually happened was clearly foreseen, and that we are in a position to say with considerable confidence what it is that has kept the earth from this year receiving one of the greater Leonid showers. This is due to the new position into which the meteoric orbit has been shifted since 1866, owing to the quite abnormal amount of the perturbations to which the meteors in the dense part of the stream have been exposed since that year. We are able to follow with accuracy what has happened to the meteors which occupy one special position in the great procession—namely, that portion of the stream through which the earth passed in 1866. The late Prof. Adams succeeded in determining what was at that time the form, the size, and the position of the immense elliptic orbit round the sun along which these meteors travel. Each of the meteors occupies $33\frac{1}{4}$ years in performing its circuit round this great elliptic orbit, which we may call Adams's orbit. Meanwhile the orbit itself is constantly undergoing slight changes in its form, size, and position, owing to the perturbating forces which are incessantly attracting the meteors towards the planets of the Solar System as well as towards the sun. Fortunately, the alterations which Adams's orbit has in consequence undergone within the last thirty-three years have been accurately followed by the skilled computers of the *Nautical Almanac*, acting under Dr. Downing's instructions and supervision, and it has thus been ascertained that the changes of the orbit due to perturbations have been of unusual amount during this revolution, chiefly because the great planet Saturn approached close to the meteors upon their outward journey, and Jupiter while they were returning. From these computations we now know fully what has happened to these meteors. The amount by which their orbit has been shifted, though of entirely abnormal amount during this revolution, is nevertheless too small to be easily made visible upon a diagram. To make it visible, imagine a sheet of diagram paper of the size and shape of a large hall-door, so large as to be 8ft. in height. Upon it draw the largest ellipse which it can take, 8ft. long and of the full width of the door. This will represent the meteoric orbit upon a scale such that every inch of the diagram represents 20,000,000 of miles in nature. A point $4\frac{1}{2}$in. above the lowest point of the ellipse will represent the position of the sun; and if we draw round this point a small circle about the size of a small dessert-plate, it will represent upon the same scale the earth's orbit. In the diagram, the two orbits have to be drawn upon the same plane; but in nature they lie in two intersecting planes which are inclined to one another at an angle of 16°. In 1866 the great elliptic orbit, accurately intersected the earth's orbit at one point. The ellipse has since shifted its position by an amount which, on the diagram, would be represented by about $\frac{1}{16}$in., but which, in nature, is 1,300,000 miles; so that at six o'clock on the morning of Thursday, Nov. 16, when the earth came closest to the meteoric orbit, the nearest point on that orbit lay inside the earth's orbit at the above distance from the earth—that is, it was more than five times as far off as the moon. Thus we know that one point in the ortho-stream—the dense part of the Leonid stream—was at this distance from us. Now the ortho-stream is known, from the duration of the great meteoric showers, to be about 100,000 miles thick; but from dynamical considerations it is known to be of immensely greater width, and we entertained the hope that its width might have carried part of it 1,300,000 miles farther from the sun than the point in it whose position we have been able to determine. What the non-appearance of a great shower this year establishes is that, wide as is the ortho-stream, it has not extended far enough beyond the point whose position is known, through which the earth passed in 1866, and which this year lay at the above-mentioned distance inside the earth's orbit. But there is a further matter of much interest. Though the earth has not passed in any considerable degree within the ribbon-shaped stream, the observations recorded in Mr. Denning's report seem to give reason to hope that we may have passed through the extreme outward fringe of it. He mentions that one observer counted a considerable number of Leonids in an opening in the clouds early on the morning of the 16th November. If other observers more favourably circumstanced confirm this observation, and have recorded the hour at which the maximum occurred, it will furnish information of real value. In fact, we know from dynamical considerations that the stream has the ribbon shape spoken of above. We also know that 17 centuries ago the width of this ribbon lay in a direction perpendicular to the earth's path; and we know that perturbations have since tended to shift it a very little round in the retrograde direction; but we cannot learn from theory what this small shift has amounted to. We shall, however, be able to determine it by observation, if the earth this year passed close to the edge of the ortho-stream, and if the time of the maximum of the somewhat aug-

mented display consequent upon this has been adequately observed.

The President asked Dr. Downing to give the meeting what information he possessed with reference to the shower for next year.

Dr. Downing said he need not detain the meeting for many minutes, as he merely wished to state the results at which he had arrived in looking forward to the conditions that would obtain on Nov. 15 next year. Unfortunately those conditions were still worse than those which prevailed on Nov. 15 just passed. That situation in the dense part of the stream, which would reach the node next November, and whose position they had been able to calculate, instead of being about 1½ million miles, would be about 1¾ million miles nearer the sun than the earth would be at the time, so that he was afraid that there was less chance than on the present occasion of there being any large display. The time when the phenomenon ought to be visible was 3 o'clock in the afternoon of Nov. 15 next, assuming that the ribbon of which Dr. Stoney had spoken lay in the direction from the sun to the earth. If, however, it were inclined, as they found reason to believe, the display would be retarded, and would come some time in the night between Nov. 14 and 15. Unless the distribution of matter round the dense part of the swarm at that part of the orbit was different from what it was at the part which we had just passed through, he was afraid there was very little chance of there being any such display as was seen in 1866. It was regrettable that the present generation should not have the opportunity of seeing such a display about which they had been reading all their lives. He was afraid that the next time the phenomenon came round, 33 years hence, many of them would not be in a position to look for it, so that this was the only time for very many of this generation, and it was really very unfortunate that it had turned out to be such a bad chance.

Captain Steele said he had some doubts whether the stream really existed. If it were a stream of any size and any dimensions, it should reflect light, and that reflected light should be shown on the photograph, if not seen by our eyes. Until he saw that the photograph had shown that this stream reflected light, he could not believe it really existed, but rather that these meteors were simply the creatures of our earth.

Mr. G. J. Newbegin said he had a feeling that we had lost the Leonids, and he would explain why. Since 1866 it was quite possible that the orbit of the Leonids might have been very much retarded and contracted by the action and influence of our major planets, such as Saturn and Jupiter. If such should be the case, the orbit had assumed lesser dimensions than it had had in past times, and in future the earth would miss the Leonid stream altogether. He only hoped he might be wrong, but that was the feeling he had about the matter.

Captain Noble thought it was to be regretted that the researches of Dr. Downing and Dr. Stoney were not made a little more public than they were. Up to the last moment they had many newspapers and magazines holding out hopes of something amazing in the shape of a display. There was no doubt there had been a great deal of penny-a-lining, as there always was on these occasions. He confessed that having read much that was written, he himself was not particularly hopeful. "Blessed," said a wise man, "is he who expecteth nothing, for he shall not be disappointed." He (the speaker) did not know that he expected anything. He was up on the morning of the 15th from midnight until two o'clock, and he thought he saw five meteors; but whether they were all Leonids or not he would be very sorry to say. When he said he expected nothing, he was bound to qualify that statement, for he was hardly in that condition. Perhaps his state of mind could be more accurately illustrated by the statement of the gentleman of the agricultural persuasion, who, when asked how much his pig weighed, said "Well, it didn't weigh as much as I expected it would—I always thought it wouldn't."

The Rev. G. Castleden thought they had had a rich harvest as a result of all the looking for the Leonids this time, in the tremendous interest which had been devoted to the matter, especially in such publications as the *Strand*, the *Windsor*, the *Standard*, and the *Echo*, and others. Although it might be said that those often got most out of it who made most ado, he thought astronomy had reaped a very rich harvest owing to this agitation. His object in rising, however, was to ask a question in reference to two phenomena which he had noticed, the first on November 13 and the other last Sunday night. He referred to very remarkable sunsets—sunsets of a brilliant golden crimson with a green sky, reminding him of those splendid sunsets in 1883, which were attributed to the dust from the eruption of Krakatao, and he had wondered whether the sunset of November 13 was sufficiently near to the time of dust scattered by the Leonids, and that of November 26 sufficiently near to the dust which might be scattered by the Andromedes to have any connection with the phenomena to which he had referred.

The President wished to ask Dr. Stoney whether the prospect of being able to photograph the Leonids next year before their striking the earth's atmosphere was better or worse than it was this year. Dr. Roberts had, he understood, made an unsuccessful attempt this year to photograph the Leonids before they struck our atmosphere.

Dr. Downing took it that the present year was the best chance Dr. Roberts had had in that matter, and that it was quite hopeless next year. He, Dr. Roberts, had attempted to take such a photograph on perfectly fine evenings, and had obtained no trace whatever of the Leonids.

Mr. Maunder read a précis of a paper on "Jupiter's Equatorial Current," by M. Comas Solà. The writer said that on examining the results obtained during several years by several astronomers, we could not fail to be surprised by the rapid changes in speed of the equatorial spots as compared to that of spots resting on the surface of Jupiter. In M. Solà's opinion, the cause was certainly outside the planet; but it was a satellite, or perhaps several satellites, invisible or small, very close to the primary, and with an angular velocity a little greater than that of the planet. The action of such satellites would be entirely on the equatorial region, and would be more ineffective on the lower strata of the atmosphere where were the equatorial bands and the great red spot than on the higher.

Mr. C. T. Whitmell read two papers upon kindred subjects, entitled respectively "Tides on Jupiter" and "The Shadows of Jupiter's Satellites." In the first he asked the question, "To what causes are due the remarkable surface changes continually occurring upon Jupiter?" and offered the opinion that the planet's high temperature was probably the main cause. The tidal action of the satellites had, however, also been suggested, and had been specially brought before him by Mr. H. J. Townsend, an able and assiduous planetary observer. In his second paper, Mr. Whitmell referred to some observations, which he previously published concerning a theory of the changes in the shape of the shadows of Jupiter's satellites during transit, and offered some additional observations upon the subject.

Mr. Crommelin said Mr. Whitmell had brought forward a very interesting point with regard to the change in the shape of Jupiter's satellites. He (the speaker) believed Prof. Schaeberle noted something about these changes four or five years ago. It was very curious that they had attracted so little attention. Of course, seen from the sun, the shadow would always be the same shape as the satellite itself. It was only the fact that we saw these shadows at an angle different from that of the line of sight from the sun to the planet that enabled us to see the change at all, and as Mr. Whitmell said that change never exceeded some 12° or so. It was certainly a point that observers might well look out for at the two quadratures of the planet, three months or so before and after opposition. The planet was then a good deal smaller than at opposition, and observation was rather more difficult, owing to the increased distance; but certainly it would be worth while to verify by careful observation these curious changes of shape. With regard to the question of tides referred to in Mr. Solà's paper, it seemed a very big order to require a new satellite—an unseen satellite—for these tides, and he (the speaker) thought Mr. Solà must have forgotten the extreme weakness of the gravitation force, which made it incredible that a satellite utterly invisible to us could produce such a striking effect by its action. The tidal action of an unseen satellite—a satellite too small for us to see—could scarcely be as great, in spite of the small distance, as that of the old four satellites. It would require many thousands of unseen satellites very near the planet. It seemed to him that these changes of rotation of different parts of Jupiter should be taken in conjunction with similar changes in the sun; there was probably a common cause for both. The different rotations at different latitudes of the sun had a very much wider relative range than those of Jupiter; but anyone who studied the different rotations of Jupiter should take the solar phenomena into account as well. He did not know whether Mr. Solà imagined several intramercurial planets to account for the changes on the sun, his theory, at any rate, would seem to require that.

Dr. Johnstone Stoney thought it would be of interest to mention that some 20 or 25 years ago, there was a paper published by the late Charles E. Burton, who was an extremely accurate observer of this phenomenon—of the elongation of the shadows when Jupiter was in or near quadrature, and who came to the conclusion that the mere oblique direction from which we viewed it did not fully account for the phenomenon, but that we must supplement that by some further operating cause, and that which Mr. Burton suggested was that the shadow penetrated obliquely—that is, obliquely as regards our point of view—down through an atmosphere of very great depth. The paper written by that observer formed an estimate of the depth of the atmosphere which would account for the amount of elongation which he observed.

Mr. Teasdale, who said he had made a great many experiments from time to time of the curious effects of photography, showed a slide which, he said, might be taken to represent something like a semi-occultation of the sun by a church steeple. It showed the absolute reversal of the image of the sun, and also somewhat excessive effects of irradiation. The plates used were Ilford ordinary. He regarded the subject as one which should be followed up, and added that the exhibition of this slide might be a suggestion to some who cared to experiment.

The President announced that they had some lantern-slides which had been prepared from photographs which had been taken by Prof. Keeler at the Lick Observatory by means of the 36in. Crossley reflector. This reflector, it would be remembered, was originally made and used by Dr. Common, from whom it had been purchased by Mr. Crossley. After having been erected at Halifax, it was presented by Mr. Crossley to the Lick Observatory, where it had been used for photographing nebulæ and star clusters with most excellent results. Prof. Keeler was, he thought, to be heartily congratulated at the success he had attained. The photographs which were then shown upon the screen and described by Mr. Wesley were as follows: (1) Spiral nebula in Canes Venatici, taken in 1899, May 10, with an exposure of four hours; (2) Spiral nebula in Ursa Major, taken 1899, June 8, exposure four hours; (3) Trifid nebula in Sagittarius, taken 1899, July 6, exposure three hours; (4) Cluster M 13 in Hercules, taken 1899, July 13, exposure two hours; (5) Ring nebula in Lyra, taken 1899, July 14, exposure ten minutes; (6) Dumb-bell nebula in Vulpecula, taken 1899, July 13, exposure three hours; (7) Great nebula in Orion, taken 1898, December 11, exposure one hour.

The President was glad to announce that the Rev. J. M. Bacon and Miss Bacon were present. They were all heartily glad when they received the good news that Mr. and Miss Bacon had finished their adventurous journey without any further mishap than that which befell them. Mr. Bacon had kindly promised to give them an account of that journey, and they would certainly all value his remarks.

The Rev. J. M. Bacon first referred to the exaggerated reports which had been circulated with regard to the injury which he and his daughter sustained in their descent, and then proceeded to describe the journey, which was made on Nov. 16, from Newbury, and which eventually terminated near Neath in South Wales. Incidentally, he said, he took upon himself his full share of blame for what proved to be a risky journey involving them in the unprecedented predicament of being aloft for nearly ten hours in a balloon that would not, and, in fact, could not, come down. They knew for certain the while, that it was travelling hour after hour towards the Atlantic (though they could not get a glimpse of the land over which they were passing), and in the end it came down of its own accord only a mile and a half short of the open sea. When it was arranged that he should make observations of the Leonids on behalf of the *Times*, he consulted their greatest authorities on the subject, Dr. Downing and Dr. Johnstone Stoney, and he was frankly told that if he would fulfil his commission properly he must have a balloon ready to start at any hour of either of the nights of Tuesday or Wednesday. He at once consulted Messrs. Spencer, the well-known aëronauts, who said the thing could certainly be done, but it would require a balloon that should be fitted with a solid or ripping valve—a valve that admitted of no leakage whatever, and no manipulation, so that it might stay in the air for many hours, and which, when once torn open, was torn open for good and all. All things being ready, he and his daughter made the ascent shortly after four o'clock on Thursday morning. At a height of 1,500ft. they entered a canopy of cloud. It was a warm, wet fog, the consequence being that before they could pierce it, the envelope of the balloon, which was a large one, became very heavily charged with condensed moisture. They had to throw out bag after bag to get it to pierce the cloud, and they then got into the cold upper current. This chilled the gas in the balloon, and rendered it less buoyant, and so sent it down again. Time after time they went up a little way, only to find the balloon descending again. They threw out as many as seven bags in twenty minutes, which meant about 3cwt., and then it was that their balloon seemed to have got its level and meant to keep there. There was no more delicate balance in existence than a poised balloon. They were then able to take observations. For the first hour they counted as many as seven meteors, none of them very striking, with one exception. One left a very lasting trail. In the second hour they were more frequent; but those that broke away upwards at that time (5 a.m.) were lost to view from a balloon such as this, for although they saw the radiant, the huge expanse of the balloon above them hid the trails that rose up towards the zenith. The most remarkable of all was the bursting of three or four meteors away from Orion in a manner which he had had never before witnessed. However, there were other things to look for. The most remarkable phenomenon was the colour of the stars. Sirius was seen flashing, not in gleams of red, but in several hues of

blue. Still more remarkable was the colour of the moon. He had seen it the purest white; on this occasion its colour was the dullest copper. There was no lack of definition. The purity of the atmosphere above was most remarkable. More noteworthy still was the dawn. It broke distinctly green at 5.58, and then all in a moment it developed into a great flood of light. He had never seen a sunrise anything like so sudden—not even in India. It had been stated in the papers that he entrapped a great quantity of fiery vapour by a special apparatus. As a matter of fact, he had wanted to carry out a suggestion made by Prof. Ramsay that he should draw a quantity of the air of the upper regions through guncotton to see if it left any special residuum of dust behind, but he had not yet tested his results—in fact, his belief was that there would be and could be no results. There was no possibility of their getting any traces of meteoric dust on that particular day. At dawn they realised that they were fairly caught in a trap. They were at a height at which it was impossible to open the valve. Their balloon had remained poised until then, but it would not poise much longer. The sun began to assert itself. The large amount of condensation on the silk began to dry, and the gas within began to expand with the heat, with the result that the balloon rose rapidly—at the rate, in fact, of 600ft. every quarter of an hour. This went on for two hours or more, until in the end they were nearly two miles high. For the early part of the time they could hear the sounds of earth, but these at last died away, and, while they heard nothing, they could only see the upper surface of the clouds, which, from its extreme whiteness, looked like the purest snow. The speaker then dealt with the nature of the upper currents, and, proceeding, said they came to the conclusion that there was nothing to be done but to let the balloon come down by itself. At about noon they heard the sounds of the pounding of great hammers, and they took it that they were over Bristol. Feeling convinced they were somewhere near possible help, they organised a system of aërial telegraphs, and, having written several copies of the following—"Large balloon overhead, above clouds; cannot descend. Telegraph to sea-coast (coastguards) to be ready to rescue, BACON, SPENCER"—they scattered them in mid-air. Only one of these had been traced, having been picked up on a Welsh mountain; the others doubtless fell into the Bristol Channel. Later they heard the splash of the waves on the shore—a continual sound as of explosion upon explosion; this was unmistakable. For some 20 miles, evidently, they were travelling over the sea. At last the balloon reached its culminating point, and when they next looked it had dropped 2,000ft., owing possibly to some cold current set up by the estuary of the Severn. They thus saw the beginning of the end, but it was two hours more before their monster balloon would at last succumb. As soon as they got through the clouds, the sun being shielded, their descent became rapid; but their aëronaut would throw out no sand until they were near earth. They fell a great distance with extreme velocity. It was the first impact with the earth that fractured his daughter's arm, and the balloon then dragged itself with considerable force over the rough country. It got caught in an old oak of considerable dimensions, carrying away a huge limb.

Mr. Bacon's remarks were illustrated by many excellent lantern slides, one being a photo. of the "Victims" (as he described himself and his daughter), after they had left the balloon. He added that many Welsh friends kindly came to their rescue.

The President expressed the hope that in future ascents Mr. Bacon would come out of his difficulties as well as he had done on the present occasion, and that Miss Bacon would meet with no further mishap.

Mr. Bacon, in making a brief reference to next year's eclipse of the sun, and the arrangements proposed to be made on behalf of the Association in connection therewith, said he had consulted one of the Transatlantic lines, and they assured him that those who wanted to witness the eclipse in America would find it easy enough to get there, but getting home would be the difficult matter, owing to the Paris Exhibition. It was necessary, therefore, that passages should be booked, at any rate, within a week or two from the present time. The voyage should not be very costly—pretty much, in fact, the same as on the *Norse King*, which was about 30s. a day.

The meeting adjourned at 7 p.m.

Drainage: Errata.—In the paragraph under this head on p. 357 some decimal points have been omitted. The error is fortunately evident.

According to the census of 1895, Saxony employs 27½ per cent. of all the textile workers in the German Empire, and upwards of 32 7 per cent. of all the persons employed in Saxon industries are in textiles. In 1895 165,459 persons were employed in the mills, and the power utilised amounted to 81,292H.P.

SCIENTIFIC NEWS.

It appears from the returns that have now been made that some Leonids were observed this year, but not in the quantity expected. Probably the earth was not in the exact position to encounter the full stream, but in 1900 or 1901 it should pass, according to calculations, through the centre of it.

The *Bulletin Mensuel* of the Royal Observatory of Belgium for July has been issued by M. L. Niesten from the Librarie Scientifique of M. L. Lagaert, Brussels. It is especially useful to observers of sunspots.

Mr. E. Walter Maunder, F.R.A.S., has an article in this month's *Knowledge* on Hippalus and its surroundings—a region which "presents a great number of features which are of peculiar value in determining the relative ages of the different types of lunar formation." It is illustrated (by permission) by the reproduction of a plate from the magnificent "Atlas Photographie de la Lune" of MM. Loewy and Puiseux.

It is announced that the Rumford Committee of the American Academy of Arts and Sciences has made a grant of 500dol. to Prof. E. B. Frost, of the Yerkes Observatory towards the construction of a spectrograph especially designed for the measurement of stellar velocities in the line of sight.

The anniversary meeting of the Royal Society was held as usual on November 30, when the reports were read, and the president delivered his address, the medals were presented, and the members of council were elected, the names being the same as those given on p. 290, with one exception, as, a nomination having fallen through, Mr. J. Bryce, M.P., was elected.

The address of the president of the Royal Society (Lord Lister) had reference chiefly to the modern systems of dealing with infectious diseases, by inoculation of "anti-toxins" and "anti-infectives." It was essentially technical, and will be read by experts with interest; but the gist of it may be given in the statement that there seems no reason why cholera, typhoid, diphtheria, &c., should not be stamped out by the modern methods of medical science. Lord Lister said that how long the protection caused by these protective inoculations would last was at present somewhat uncertain. It would, no doubt, differ in its duration in different diseases. In the case of cholera it appeared from Haffkine's results that it continued for upwards of a year. In plague, so far as could be judged hitherto, it would also seem to last for at least a twelvemonth. With typhoid there were not yet materials for forming an estimate.

Applications for a portion of the Government grant of £4,000 to defray the expenses of scientific investigations should be forwarded, upon the printed forms, to the clerk to the Government Grant Committee, Royal Society, Burlington House, W., by Jan. 31, 1900.

Amongst the papers that are in the list for reading after Christmas at the Society of Arts is one by Prof. W. Boyd Dawkins, M.A., F.R.S., on "Coal in South-Eastern England," and the following item of news may be of interest:—"Another thin seam of coal was passed through on Saturday at the boring at Ropersole, between Dover and Canterbury. The seam was 6in. thick, and of excellent quality. This makes the third thin seam passed through at this boring, which had been stopped for many weeks owing to a part of the machinery being lost in the operations. From fossiliferous evidence it is believed that the boring is passing through the upper coal measures. If so, the carboniferous strata must continue to a very great depth in this part of Kent."

At the meeting of the Society of Arts on Dec. 13, Mr. F. G. Aflalo will read a paper on "Sea Angling and Legislation." The concluding lecture of Mr. H. H. Cunynghame ("Art Enamelling upon Metals") will be delivered on Monday, Dec. 11, and will deal with the application of enamel to jewelry and with goldworking and gilding.

It is announced that Sir W. C. McDonald, of Montreal, whose gifts to the McGill University have made him justly celebrated as a benefactor to education in Canada, has placed in the hands of Prof. Robertson, Dominion Agricultural Commissioner, sufficient funds to establish for three years technical schools in various centres throughout the Dominion. The nature of the plan is to take one city or town in each province in which to establish regular classes in some of the ordinary schools on one or two days a week, in which scholars between nine and thirteen years of age shall spend a portion of the day in actual work with tools. This will be supplemented wherever desired by more advanced and special evening classes in manual training and technical instruction.

In a memoir presented to the Paris Academy of Sciences, M. H. Moissan says that the statement that anhydrous hydrofluoric acid does not attack glass is erroneous, as although the glass may retain its polished surface, it loses in weight. Experiments show that glass is invariably attacked by gaseous hydrofluoric acid even when that is thoroughly dried. Perfectly pure fluorine, however, may be kept in sealed glass tubes for some time without the glass being attacked.

At a meeting of the Society of Chemical Industry (Manchester Section), Mr. T. Aspinall read a paper on the oxidation of organic matter by liquid chlorine. He said that for nearly a hundred years chlorine had been used for oxidising colouring matter in cotton and other fibres and organic matter in the air. At the latter end of 1896 he began to carry out a series of experiments with chlorine to see what effect it would have on the oxidation of soluble organic matter in sewage and sewage effluents. The chlorine he used cost 6½d. per pound delivered. He described the experiments in detail, and claimed that they showed conclusively that the oxidising properties of chlorine are very effective. The chairman (Dr. Grossmann) and other members expressed the opinion that the cost of the chlorine would prohibit its use in dealing with large volumes of sewage matter, the chairman stating that for the Manchester sewage the cost would be between £30,000 and £40,000 a year for chlorine alone, to say nothing of the lime process, which *would* be used first. Mr. Aspinall, in reply to this, said there was nothing to hinder the Manchester Corporation from putting down chemical works and generating chlorine as a by-product.

The war is bringing into the newspapers notes which rarely appear in them. Thus it is stated that the Boers blew down the Frere bridge with roburite, which they probably obtained from the Natal coal-mines. It is one of the explosives specially authorised by the Coal-Mines Regulation Act. It was devised as an explosive which should bring down the coal in masses, without giving out any flame to ignite coal-dust or inflammable gas. In order to achieve this result, a mixture of nitrate of ammonium, of nitrobenzol, and chloro-naphthalene is employed in sealed cartridges, which must, according to the Act, be exploded by an electric detonator. The composition is defined in the "license," but the roburite is not a military explosive, and requires a powerful detonator to develop its force. Roburite is flameless, but a committee of the Miners' Federation reported in 1889 that, owing to the necessarily imperfect ventilation of a coal-mine, the health of the miners was injured by the nitric oxide and carbonic oxide gases set up by its explosion.

M. Curie and Mme. Curie have forwarded a note to the Paris Academy of Sciences, in which they state that radio-active chloride of barium possesses the property of converting oxygen into ozone—which is proof that the radiation represents an expenditure of energy.

It is stated that M. de Santos Dumont claims to have made a successful flight round the Eiffel Tower in his steerable balloon. "It is cigar-shaped, with a wicker car and a screw propeller. To drive the aluminium screw, which makes over 1,000 revolutions a minutes, he uses a petroleum motor. The car is constructed of rattan cane and wicker suspended from a steel trapeze by cord. There are two safety-valves made of aluminium. A very light japan silk is used for covering the balloon, a special varnish making the silk impenetrable by air." Why the "steel trapeze" and the safety-valves of aluminium should be introduced is rather puzzling, unless the reporter considered them to be important points in connection with a steerable balloon.

Sir Henry Tate died on Tuesday morning last, aged eighty years. His fortune was made by a machine for cutting or making sugar in cubes—an invention which other sugar refiners had refused to take up.

Mr. William Franklin Durfee, whose contributions to the *American Machinist* we have often quoted, died last month in his sixty-fifth year. He was a native of New Bedford, Mass., and early in life turned his attention to metallurgy and mechanics. In conjunction with William Kelly he produced some ingots of steel, from which, in 1865, the first steel rails rolled in America were made. Soon afterwards he established the first analytical laboratory as an adjunct to a steelworks in the United States. In 1876 he was one of the judges of machine tools for wood, iron, and stone-working machinery at the Philadelphia Centennial Exposition. Later he built the first successful furnaces for refining copper by the use of gaseous fuel. He had a collection of rare and curious books upon mechanical topics, which, it is stated, will go to the American Society of Mechanical Engineers.

The Westinghouse Electric Company are about to build the largest generator yet constructed. They are about to erect extensive works at Manchester, and have secured a unique order from the Manhattan Railway Company. The apparatus covered by the contract consists of eight three-phase alternating current generators, each of 6,650H.P. capacity, with such step-down and converting devices for the railway company's sub-stations as will be necessary to transform the alternating current in the power-house into direct current of 500 volts. These generators will be the largest ever designed or constructed. Their external dimensions will be something over 40ft., while the rotary element has a diameter of 32ft. Each machine and engine complete will weigh nearly a thousand tons. The largest electric generators ever previously constructed were of 5,000H.P. capacity, and these were by the Westinghouse Company.

The tendency to increase the heating surface in locomotives is growing in the practice of modern designers. It is stated that some new locomotives ordered of Stewart and Co., Glasgow, by the amalgamated S.E. and L.C.D.R. Co. are to have 30 per cent. more heating surface than the latest type of express engines placed on the company's lines.

USEFUL AND SCIENTIFIC NOTES.

Tensile Strength of Iron.—The tensile strength of wrought iron or steel appears to be a minimum at about 70° Fahr., and increases as the temperature is changed in either direction, becoming about 20 per cent. greater at about 500° Fahr. and at 60° below zero. There are indications of a brittle region at the temperature of steam at 5lb. to 10lb. pressure. Iron at low temperatures, while increasing in strength, retains its ductility. In the case of cast iron the tensile strength remains constant from 70° Fahr. to 700°, decreasing from that point to zero at 1,240°.

THERE are now three Scherzer bascule bridges across the Chicago River, one being a four-track railway bridge, while the others are highway bridges. Two other bridges of this type are now to be erected, to replace old swing bridges whose centre piers are to be removed in order to give the river the necessary capacity of flow required for the Chicago drainage canal. The bridges will give a clear channel of 120ft. between the guard piles, measured at right angles, and the river will have the required capacity of 300,000c.ft. per minute.

Blocking Out Skies.—Many negatives have what are known as "dirty skies"—that is, the sky of the negative is thin in parts, thus making a muddy or tinted sky in the print. If clouds are required on the print, the sky, of course, must be perfectly white, otherwise they would print in flatly. There are two methods of blocking the skies out on the negatives—painting out and pasting out. The former is the one usually resorted to, and is done as follows:—Obtain a tube of ivory black oil paint, a small sable, and a hog's-hair brush, also some turpentine. Squeeze a little of the paint out, and carefully paint round the edge of the sky against the horizon. Care must be taken that the colour does not overlap any part of the view. Next use the hog's-hair brush, and paint all over the rest of the sky. Every bit must be covered, or it will print patchy. The sky must look perfectly opaque when viewed by transmitted light. The only disadvantage to this method is that the paint takes several days drying. The other method is to do an untoned print of the negative, place on a glass film, side up, and with a sharp penknife carefully cut away the view, leaving the sky intact. Then smear some thin paste all over it, and place on the sky of negative, to register exactly. If carefully done, the sky will print perfectly white.—"O. T.," in *Photographic News.*

LETTERS TO THE EDITOR.

[*We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.*]

All communications should be addressed to the EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

*** *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks; a vice from whence great inconveniences derive their original."—*Montaigne's Essays.*

VARIABLE STAR OBSERVATIONS, NOVEMBER, 1899.

[43090.]—T CASSIOPEIÆ passed a minimum, 11·3 magnitude, September 29. The interval since the previous minimum, 1898, July 31, is 425 days. By the end of November it had risen to about 10 0 magnitude.

S Persei has been slowly declining for the last five months, and was observed 10·0 magnitude, October 25. This was the faintest magnitude of the star since July, 1893. The changes are very slow, and the extreme range during ten years observations is about three magnitudes.

R Ursæ Majoris has gone down about five magnitudes since the maximum on August 12. At the end of November it was 12·5 magnitude, and for the next two or three months will be a very faint and difficult object. The minimum will probably occur about the end of January, 1900.

R Camelopardi has made a rise of about three magnitudes in the last four weeks, and will for the next three months be a conspicuous object. The maximum will probably occur about the middle of January, 1900, when the star will be about 8·0 magnitude.

S Herculis has declined rapidly during November, falling from 8 2 magnitude on the 6th to 9·5 magnitude on the 26th.

S Cygni, after remaining invisible for about 184 days, was first observed on its reappearance Nov. 10, when it was a most minute 13·5 magnitude, and about the limit of vision for this telescope. The magnitude was 12·5 Nov. 26, and it will soon become an easy object.

Instrument in use 6·4in. equatorial refractor. Weather has been very unfavourable, with much dense cloud. Observations were only possible on eight nights. C. E. Peek.

Rousdon Observatory, Lyme Regis.

AMATEUR'S OBSERVATORY.

[43091.]—WITH reference to the friendly remarks and criticisms of Mr. Jenkinson (letter 43050) on the above subject, I should like to remark generally that I have had little or no experience in small telescope houses. This particular house was designed to meet my general requirements, the details being all carried out by my highly intelligent and practical master artificer, who I am pretty certain knew nothing about observatory needs when he started this job. Hence some of the work may not be in accordance with the regular type.

As to rollers, no doubt Mr. Jenkinson is right. Larger ones than those I have would work easier, especially when the iron bars mentioned are used for the rollers to run on. But, as a matter of fact, I do not notice very much friction at present.

As regards the roof, four iron hooks are provided inside building at top, which engage in iron staples on the roof. These effectually hold down the roof, and if that went, the house would have to go with it. It is only a short time back we had a heavy gale, when a vessel was wrecked in Plymouth Sound. The morning after we were pleased to note that no damage whatever had been done to the "house." It was still (nearly) as firm as a rock, and quite dry inside.

I think the idea of the roof divided into two parts an excellent one, as each part must obviously be easier to move, and a portion only can be opened as required. I find a great convenience in my roof is leaving it 18in. or 2ft. "on" at the E. side. I don't usually observe low down in the eastern sky, and that portion of the roof not "off" makes a shelter for books and papers, as well as the observer recording his notes, an aid not to be despised on a cold dewy night.

Then, as to the pulleys: doubtless they are most convenient, provided your runners and roof work perfectly smoothly; but as the pull is limited to only one direction, I can easily imagine a case where a jam would occur, necessitating application of pressure by hand direct on the roof. We thought of pulleys at first, but for some reason or other did not try them. First we had a strong stick or handle with an iron crook and loop, so as to be able to push or pull roof as desired. This was a failure, and was discarded in favour of iron handles. With your back to the wall, and a good grip of the handles, any tendency to jam or sag is easily overcome, and the roof runs off merrily, but not all the way, for the telescope obstructs the movement. Then comes the necessity to step outside and complete the motion by "walking the plank." The whole operation only takes a minute, and the roof can be closed "home" by one motion from the outside. The handles are simply plain pieces of round iron about ½in. diameter, and are secured firmly to the central rib of the roof, from which they project horizontally in three pairs, one on one and one on other side.

In query 97066, "Nemo" asked about an observatory lamp. For years I have used a tin candle lantern, black japanned on the outside. Two arches of tin at top, open at sides, and at right angles to each other, prevent the handle at top fall getting inconveniently warm, the handle itself being triangular with flat side uppermost. The lantern is square in section, the sides being all tin, except one which has a small window inserted say 3in. by 3in. This is glazed, and is used to throw a light on the observer's path to the observatory, which is over somewhat uneven ground. The side opposite the glazed part is hinged to open and shut. A small piece of blackened tin is kept ready for sliding over the window, thus shutting in all light (or nearly all). On recording the observation, the door is opened as required and closed again for next observation, the window being kept closed during the hours of observation. Four circular holes are bored in the floor of the lantern for coolness, the floor being supported on four little points of tin about ½in. high. When using good *hard* candles, I have found the lamp do very well. Just towards the end they do run a little, but the wick lasts until it commences to flutter, when a fresh piece of candle is popped in, the heat of the socket fixing the new piece at once. Occasionally one has to furbish up the whole concern, and clear out any wax that may have accumulated on the floor. This may be all very old-fashioned, and no doubt inferior to the electric light. Still it answers the purpose, and I do not propose to change it. The lantern could be made to order by a tinsmith for 2s. at the outside.

Devonport, Dec. 1. E. E. Markwick, Col.

SODOM DESTROYED BY THE LEONIDS.

[43092.]—THE "F.R.A.S." talks (p. 359) of my "habit of arguing merely for victory," but I should like to know for what he argues. He cannot mention the destruction of Sodom without inserting "mythical." Simply because Christ referred to it (Luke xvii. 28) as equally certain with His own return to judge the world, a Jew cannot mention it but as "mythical." We must even "*remember* Lot's wife," as "Silverplume" says, p. 360, to deride the whole story of her. I never repudiated "Usher's chronology when it conflicts with" my wild assertions, but only when it conflicts with the genuine Bible, and all other good chronology. In fact, Ussher was a painstaking and learned chronologist, and eminently to be believed where he reasoned from genuine records, which means, in all dates subsequent to the birth of Abraham.

That is the very last event wherein the various copies of Genesis agree. Before it they all differ, and indicate plainly how their differences arose. The Jews, or rather their Rabbis, in our first century, altered the numbers in a systematic manner, to reduce the age of the human world, that it might appear the time for the Messiah was still future. But the incorrupt figures in Genesis agreed exactly with the Hindoo chronology, and this agreement, a most remarkable one, is kept entirely out of view. The Hindoos, unlike the Jews, had no religious motives for keeping up false chronology. Their date for the Deluge is, therefore, always kept unaltered, and it agrees with that of the Samaritan Genesis, the only copy moreover, of Chap. xi., where the complete life of each patriarch is given, ending with the phrase "and he died." In our present copy of Genesis xi., we cannot really prove that any of the men named, between Shem and Terah, ever did die. They may each have been translated like Enoch.

Neither Ussher nor your "F.R.A.S." can have ever arranged the lengths of the patriarch's lives in a scale like this—

Had they done this, it would at once have been obvious to "Ussher" or any modern that all those from Adam to Abraham have been carefully doctored, to shorten the whole time. The Greek copy alone keeps all the full numbers. The Samaritans were cunning enough to alter only those of Chap. v., thus leaving the true date of the Deluge; but the Jews altered those of Chap. xi. besides.

Leverrier's story of the Leonids originating in A.D. 126 is utterly disproved. He reckoned from

an estimate of the comet's period, made only from the single appearance in December, 1865, and January, 1866. This estimate, 33·18 years, was a wonderfully good one, perhaps the best that ever was made from a comet's single visit. But the identifying the comet with that of 1366 alters the whole problem utterly. The shortest period really allowable now is 33·295 at least. That exceeds 33·18 by ·115 of a year. We have to go back 52 periods, and that makes the approach to Uranus's orbit six years earlier. It disposes utterly of all Leverrier's reckoning. Indeed, his making any, from such data as he had, was foolish. Even Uranus's period is hardly well enough known. The comet's is now better known than that of Uranus, in the proportion that 499 years exceeded the time since Uranus was first observed, which was in 1690, barely two centuries ago. E. L. Garbett.

IS THE UNIVERSE FINITE?

[43093.]—WE may not be in a position to decide whether the universe is finite or infinite; but in considering the question it is important to get rid of some superficial misconceptions which render many persons blind to the force of argument in favour of finiteness—an argument which is at all events difficult to answer.

As regards the total light or total heat of the sky, it is obviously of no consequence whether we have a single star of the brightness of Arcturus or a million of stars, each giving one-millionth part of the light and heat of the latter. And, again, it is of no consequence in what way this million of stars is distributed over the sky. The light and heat does not become inoperative because it ceases to be separately perceptible even with a fine instrument.

Now the broad fact is, that on the theory of an infinite universe we should expect the general illumination of the sky—the total starlight—to be enormously greater than it is. Enormous distances and consequent extreme faintness are suppositions that answer very well when we are dealing with individual stars; but they entirely fail when we are treating of classes of stars whose individual faintness ought to be more than compensated by their number. The total light and heat of the sky is made up of an aggregate of very small quantities, for the most part separately imperceptible. The remarkable fact is that this aggregate is so far short of what we should expect.

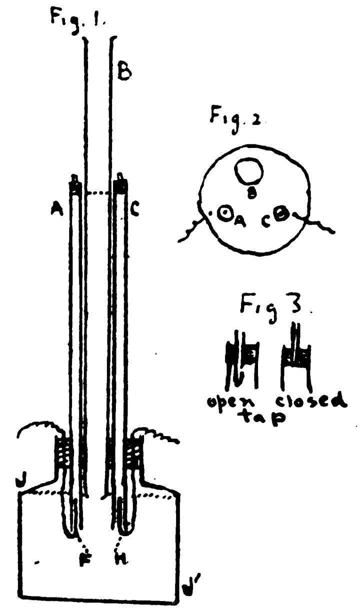
The spurious discs of the stars deceive us as to the portion of the sky that is really covered with them. The surfaces of the stars composing a cluster like that in Perseus or Hercules are probably as bright as the surface of the sun. But how vast is the difference between the brightness of that little grey patch and that of an equal angular extent of the sun's surface? Probably no such patch has $\frac{1}{100}$th of the brightness of an equal angular extent of the moon's illuminated surface, which may be set down as $\frac{1}{500000}$th of the sun's. The inference appears to be that even in these dense clusters the interspaces exceed the genuine star discs in the proportion of 50,000,000 to 1. W. H. S. Monck.

THE MOON AND THE WEATHER.

[43094.]—THE moon has nothing whatever to do with the weather. That is dogmatic, but it is true, because the place of the "weather" must be defined, and then, if the moon is brought in, it will be found that the weather at A is different to that at B, even in these islands; and if the moon has anything to do with it, how account for the variations which, thanks to the telegraph, we know occur? The "terrestrial pulsation" mentioned by Mr. Schucht (p. 361) will not do, for is it a fact, or does anyone suppose, that the weather in London is the same at any given date (allowing ample margin) as it is in, say, California or South Africa? The fact is (so far as is known) that weather is purely local, and, whatever may be the cause, it seems certain that neither the moon nor terrestrial pulsations can have anything to do with it. S. R.

ELECTROLYSIS OF HYDROCHLORIC ACID.

[43095.]—THE failure of this experiment is evidently due to the resistance of the liquid in the quill tubing, as already surmised by "Technicus," letter 43071. A simple and efficient substitute for Hofmann's apparatus is shown in the inclosed sketch, and can easily be constructed out of the material you already have with but little addition. In Fig. 1 S S' is a wide-mouthed jar or bottle, fitted with a bung about 3in. in diameter. A and C are your 2½in. tubes, and B is the 1in. one, all passing through holes bored in the bung. The relative positions of the three tubes are shown in Fig. 2, and in Fig. 1 it may be noticed that the tubes A and C dip further down into the jar than B. The platinum electrode F, and the graphite one H (a short length of ½in. arc-carbon is much better) are suspended in the tubes A and C by means of bent and well-paraffined copper wires, the ends of which project through the bung (which is also well paraffined) for battery connections. The taps of A and C are opened, and acid poured into B until A and C are quite full. The levels of the acid in the jar or in B at this point of the experiment are shown by dotted lines in Fig. 1. Before use, the pure and concentrated acid is saturated with chlorine gas by bubbling it through the acid until it attains a deep-brown colour and gives off chlorine freely at ordinary temperatures. The chlorine prepared by the usual method of acting upon manganese dioxide with warm and concentrated hydrochloric acid may be used. By using this prepared acid I have found



that after a few minutes unequality (perhaps due to occlusion of chlorine in carbon), the gases hydrogen and chlorine come off in almost equal volumes. If the above instrument is carefully-made and mounted upon a wooden stand, it has quite a high-class appearance, and, what is of more importance, works well. An extremely neat and simple tap for tubes A and C, is shown in Fig. 3, and consists of a short piece of glass tubing closed at the lower end, and with a small aperture fitted in its side. The tap is opened and closed by sliding the aperture out and into the cork which is inserted in the ends of A and C, as shown in the figure. As to the second part of your letter, just as in the electrolysis of sulphuric acid and water and nitric acid and water, the water *does* enter into the electrolysis of hydrochloric acid. According to Grothuis's theory, regarding hydrochloric acid for simplicity as H_2Cl_2 and water as H_2O, you have H_2 liberated at the platinum electrode, and the nascent Cl_2 thus liberated seizes hold of the H_2 of the nearest molecule of water forming H_2Cl_2 and O. The nascent O then unites with the H_2 of some more hydrochloric acid forming OH_2 and setting free Cl_2. The action is thus passed on till you have Cl_2 free at the carbon electrode, thus—

$Pt\,(H_2Cl_2)H_2O(H_2Cl_2)\,C$ before electrolysis.

$Pt\,H_2(Cl_2H_2)(OH_2)Cl_2\,C$ after electrolysis.

Chemical.

NATURAL HISTORY STORIES.

[43096.]—IN the winter of '82, I think the winter of the great blizzard, I had the pleasure of company to breakfast a robin for better than three weeks. He made his entry one bitter morning when it was a very hard frost and three inches of snow upon the ground. He tapped at the breakfast-room for admittance; when the window was opened he flew in and mounted the breakfast-table, and seemed quite at home. After breakfast, if the weather was fine or sun out, he would go away, only to return just before sundown. At night I would find him perched upon the corner of the bedroom-door, and we left the door open for him, not liking to disturb him. When I passed he would always greet me. My duties called me up at 5.30 of a morning. He would always greet me; but otherwise did not seem disturbed. Some boisterous heavy snowy days he did not go out. One morning, after breakfast, the snow having disappeared in great patches exposing the ground, being when I made my exit to return to my duties, he gave a chirrup and disappeared with me, and we have not, to our knowledge, seen him since.

We had a large black buck rabbit that used to run about the house tame like a cat. I was residing at Westminster then, and he was a pet with over 200 workmen that used to come to and fro. He used to make his way into St. James's Park, and led the police a nice game: he was a fine fellow, with drop ears. At last the police caught him, and took him to Charles-street Police Station for trespass. I had to go and bail him out and be responsible for his future good behaviour.

Many times, when writing or making sketches for the "E. M.," I have had a canary perched upon my shoulder or on the top of my head, or a large red-and-white Tom cat perched upon my shoulder, combing my whiskers with his long talons, and driving his cold nose in my ear; and if turning or fitting, he would come and mount my shoulders, and hang on like grim death, talking and answering me in his way.

When writing, I have had pet rats, white and piebald, working their way down my neck to get around my breast or lodge themselves in my shirt-sleeves, which was a favourite place with them.

One place where we resided we had a visit three seasons from a family of swallows, who persisted in coming down the chimney to be let out of the bedroom window. My wife persisted that it was the same family every year.

When visiting an elderly person, who was a widow of an old Waterloo veteran, I tapped at the door, when a voice says, "Come in, please; but gently, or you will frighten my poultry." I did as desired, when I saw a sight such as I had never seen before or since. The old lady's window had three panes of glass once; but she had the centre one taken out, and a long board fixed in at the bottom of the entry, thus forming a platform inside and out. When I entered I should say there were over twenty sparrows scrambling over one another, and playing all manner of pranks, and thus afforded this poor, lonely old lady many an hour's amusement in watching them.

However, my business with her was to bring trouble, for the house that she occupied a sky-parlour in was wanted;—it must come down to make room for improvements. I was very sorry for her. I promised to find her a place and see her comfortable; but the old lady grieved very much, as she would lose all her pets, as both she and I thought; but no such thing. Although some considerable distance away in a more confined locality and a first floor instead of third, in a very few days they found her out, and when I visited her I found her with her flock and quite happy.

I see in one of the magazines that a naturalist, and many doubt the statement, that a viper swallows its young when they are in danger. I was an eye-witness of such a performance when making my way from Wood-street to Pitch-place, near Worplesdon, Surrey. It is a thing that very few have a chance to witness.

Jack of All Trades.

"FLYING" CRABS.

[43097.]—CAN any of your readers give some description of what amongst Cornish fishermen are known as "flying crabs"? It appears that recently one of the Port Isaac herring-boats took in its drift nets upwards of 100,000 small "flying" crabs, which by means of two long thin blades or fans at the rear of their bodies are enabled to propel themselves through the water like an ordinary fish, and with much rapidity. The chagrin of the men was great, as many hours of patient toil were required to clear the meshes of these tenacious crustacea, and with a probability of considerable damage to the nets. Another boat was burdened almost to a similar extent. It is thirty years ago since any Port Isaac fishermen had such a peculiar and unprofitable catch. The nets then had to be spread out as far as was practicable in a field, and left there for some days until the crabs were dead.

It would be interesting to learn the size of the mesh of the nets and also of the "flying" crabs, that they are caught in such numbers. Are they sprat nets? Dormus.

POISON IN FISH.

[43098.]—I LATELY received some whiting, as usual, from a smack-owner at Grimsby. As to freshness and general appearance of excellence, they were all that could be desired. They were cooked on the day of arrival, and four persons out of seven who partook of them were seized with sickness, three of them immediately and suddenly, two being members of the family and the others the cook and another servant. The symptoms came on about 15 or 20 minutes after beginning to eat. They were sudden cessation of appetite, nausea, giddiness, fulness of the head, and a strange feeling in the arms; in one case in the legs also, described as a shaking with weakness, but without any actual spasms or movement, except in one case, where there was actual trembling. The two members of the family immediately got rid of the contents of the stomach by vomiting, and the cook vomited four times at intervals of about ten minutes from the invasion of symptoms.

The cook's description of what she felt is as under: "About 20 minutes after beginning dinner, felt something first in the arms, as if there were something rising up in all the sinews of the fingers, as if being drawn; then same feeling went to back of head. No pain; then a curious trembling feeling began in stomach, and worked all the way up until

I was sick; lump in the bottom of my throat; nausea and vomiting in ten minutes."

The second servant who suffered felt nothing till about three hours after eating, when she had what she called a "trembling inside," and not in her arms, which soon passed off.

It is thought that the illness in all the four cases was caused by a single fish, of which the two members of the family took each a little, not more than ten minutes before the symptoms came on, and the cook afterwards took a larger quantity, and the other servant affected only a very little. In two of the cases there was very slight bowel disturbance shortly after. In all the cases except the last there was still some feeling of ailing even next day.

I should be interested to have any probable explanation of this case. What poisons are there which can act in this way with such rapidity? Ptomaines, so far as I have observed, produce no sensible effects for some hours. What else can be reasonably suggested? L. C.

STONEHENGE.

[43099.]—It is from the evidence of the tumuli that I am led to believe that the great monument of Salisbury Plain is of a high antiquity. The contents of these tumuli indicate for *them* the date of the "Bronze Age," so-called. Within these tumuli have been also found pieces of the stone, which has been used in the erection of the circles of Stonehenge. This stone is not found naturally anywhere in the neighbourhood, Salisbury Plain being a chalk formation. Hence probably the stones were erected *before the tumuli were raised*. To attempt to *calculate* the age of Stonehenge from any astronomical data seems to me the height of absurdity; but the general public are easily misled by statements such as "that Prof. So-and-So has determined its age by astronomical calculations." F. B. Allison.

POLISHING AND GRINDING MACHINE FOR GLASS SPECULA.

[43100.]—As promised in my last letter, I now send you a photo. of Mr. Glass's machine for grinding and polishing glass specula. The largest size of mirror worked has been 8in.; but, with slight alterations, it would take a much larger disc. The following figures give the ratio of the various movements:—48 revolutions of driving-handle to 1 of speculum, 19 of ditto to 1 of oval wheel, and 240 of ditto to 1 of tool.

Two tracings, executed by a duplicate of this machine, which was made by a gentleman in the district, appeared in your issue of July 23, 1897.

Dalbeattie, Nov. 18, 1899. Alex. Smith.

DIRECT POSITIVES.

[43101.]—Mr. Dormer (43082, p. 361) states: "The negative image is first developed, then removed by persulphate of ammonia." There is no need to destroy the image by persulphate, for if the plate be removed from the developer directly all necessary detail is out, the negative image formed will be very thin, and another exposure may be made (prior to fixing, and through the film, of course) by gas or other light, and a fairly satisfactory positive obtained. When fixed, provided development has not been allowed to proceed too far in the first place, the negative image can scarcely, if at all, be perceived. By this method, when a plate is much under exposed, a positive may be made, and subsequently a negative obtained, which will be more satisfactory, at any rate as regards density, than would be the case had development been allowed to proceed in the ordinary manner. A better result will be obtained by using rodinol, metol, or other detail giving developers.

Earlsfield, S.W. Silverplume.

DENSITY AND SPECIFIC GRAVITY.

[43102.]—"Technicus" (letter 43037) is puzzled about the meaning of these terms. They are very often used loosely one for the other. In textbooks of physics, "specific gravity" is the term more generally used, the standard of comparison being water in the case of solids and liquids, and air in the cases of gases. In textbooks of chemistry, on the other hand, the term "density" is the more usual. The standard of comparison used is hydrogen, and the density of a substance will thus mean the ratio between the weight of a given volume of the substance in the state of gas compared with the weight of the same volume of hydrogen, the pressure and temperature being the same in the two cases.

Density is also used in a more limited sense, as the ratio between the amount of matter in a body and the space it occupies; thus, taking the foot and the pound as our units, a body has unit density when one cubic foot of it weighs one pound. According to this standard, the density of water is $62\frac{1}{2}$. Avogadro's law is all right. Molecules are supposed to be all of the same size, but of different weight; and therefore equal volumes of gases, though equally compact in so far as they contain the same number of molecules, will not have the same weight. A molecule of carbonic acid is 22 times as heavy as a molecule of hydrogen, and therefore a million molecules of carbonic acid will weigh 22 times as much as a million molecules of hydrogen. Density.

THE ORIGINAL STATE OF CARBON IN NATURE.

[43103.]—When in the company of a friend the other day, we had occasion to discuss the original state of carbon—i.e., before any organic structures existed to bring it into circulation in the economy of nature as we now see it.

We all know the existence of animal and plant life would be an impossibility without carbon in some form or other; hence, from the very dawn of all organic life, the original, natural store, whatever and wherever that may have been, of this element must have been drawn upon to maintain the necessary chemical changes which always accompany manifestations of life on our plane. As a consequence of this, there is but a very limited quantity of carbon, it seems to us, which has not at some time or other in the earth's history been used by, and formed part of, animal and plant structures. As far as we can see, excepting the carbon dioxide in our atmosphere, the only large store of carbon we have is contained in the coal-measures, and in the limestone rocks as a carbonate; but these cannot have been its original states, since both of these, according to the teachings of geology, are petrified plant and animal remains.

The question arises: Where and in what form did carbon exist originally? In the air as carbonic acid or in the earth in combination with metals and minerals?

According to textbooks of chemistry, there is some carbon in combination with inorganic substances in nature, such as in sea-salt, barium, ironstone, &c., as well as in a nearly pure state in the diamond. But the quantity from all these sources combined would only be infinitesimal as compared with that which has been, and is, in circulation for the use of organic life—i.e., in the coal, in the limestone rocks, in the structure of plants and animals, and in the atmosphere.

Carbon is a most interesting element in many respects. It has not been, so far, produced as a liquid or a gas, and it has the curious property, in a higher degree than any other element, of "uniting with itself." But what renders it still more interesting to the student, is the fact of its inseparable connection with the very existence of all forms and manifestations of terrestrial life.

Lower Brynamman. D. J.

THE DIALYTE.

[43104.]—Replying to the kind letter by "H." (No. 42983, p. 276), I would say the old Gregorian gives me every satisfaction that could be expected from an instrument of its limited aperture ($2\frac{1}{2}$in.)

Lunar views by it are magnificent, and its extreme sharpness of definition is always a matter of surprise and satisfaction. I may mention in passing that its focus is so sharply defined that, when correctly adjusted, a movement of the small mirror of one-fiftieth of an inch either forward or backward is quite sufficient to confuse the view, which seems to me to prove that the figure of mirrors is very accurate. But it is a very small mirror telescope after all, and its powers are quite limited. I have been unable so far to see the companion to the Pole-star with it, but hope to do so on some very clear moonless night. I think perhaps its most striking effects are when used upon terrestrial objects at eight or ten miles distance, the amount of detail shown and the clear definition of small objects being very surprising in an instrument of its size.

I wish also to express my thanks to "H." for furnishing the address of Mr. Ingall; but I do not think it will be necessary to write him at present owing to the results I have reached in experimenting with the dialyte.

I have received several letters from American readers of the "E. M." since you published my inquiry, all giving me advice on the subject, most of which was to the effect that the dialyte was useless, and one of them kindly gave me several references to back numbers of "E.M.," among them being one at p. 61, Vol. LVI. Having looked up all of these references in a public library, I find this particular one to be the only one of interest, and note that the writer speaks of a strong display of colour in the borders of the field of view, although

the centre was achromatic and satisfactory. Now, although this writer's instrument was a dialyte of the crudest possible construction, yet this statement, taken in connection with all I had received from other sources, was very disquieting, and I determined to find out some facts for myself without delay.

I had already finished the mountings of the corrector lenses, and on November 16th I proceeded to mount everything on the wooden bar that I had used originally, and fix it so that it could be directed to the Pole-star, and rigidly held in position. I selected the Pole-star, as it has practically no motion, and so I would not have to follow it; the instrument once fixed in position could remain so while I changed its details and adjusted its parts. Again, I thought the small companion to this star would prove a good object to test the definition of the margin of the field of view in comparison with its centre. I provided enough movement to the eye end of the instrument to enable me to get the star into any portion of the field I might select for trial.

Having all ready, and the night proving fairly clear, the process of adjustment began, and you may readily believe I found out a great deal about the dialyte. Not to weary you with details, I will merely say I found that the position of the corrector lenses had to be materially changed from that which I gave in my first letter, and which was found from terrestrial observation alone. The lenses remain in the same relative positions—viz., crown lens nearest o.g., with convex side towards o.g., flint lens nearest eyepiece, with concave side towards e.p.; but the distance from o.g. to first surface was reduced to 25¼in., and the lenses of corrector require a separation of very nearly ⅛in. The focal length of the combination is now 56in., and it is perfectly achromatic, while there is no difference perceptible in the definition at any part of the field of view. The Pole-star and its small companion are both satisfactory in this instrument, the small star showing beautifully distinct to the extreme edge of the field of view, with a power of 65.

I am now satisfied that the telescope will prove a very good one, and shall proceed to finish it up on these lines, and will try to give you particulars of its performance when finished. I will also send you some sketches of the details after a time, if you think they would prove acceptable, for I have introduced some novelties into the corrector mounting and the eyepiece end, designed to give rigidity, and provide for ease of adjustment.

I thoroughly agree with "H." regarding the poor workmanship in many telescopes, even by professional makers. A friend of mine has a very good 3in. achromatic by a well-known American maker, and the straight adapter fitting into the bushing of draw-tube at one end, and carrying the eyepieces at the other, having been lost, he came to me to get a new one made. I found that the bushing of the draw-tube was neither round nor straight; nor was the screw by which it was held true with any part of the crooked-bar.

Yet this was supposed to be "good enough" for a telescope. A steam-engine built with as little regard for truth would never be expected to give satisfaction; but a telescope is supposed to be all right any way, and the amateur constructor calmly sets his lenses in paper tubes, and squints at the heavens and then remarks that the lenses are not quite perfect; but, on the whole, they are pretty good.

I wish "H." or some other competent authority would give me a rule for finding the proper diameter of diaphragm opening, and its position in relation to the lenses for the Huyghenian form of eyepiece, as I intend to purchase the lenses and make my own eyepieces, and can find no rule for the diaphragm. E. P. Clark.

245, West 18th-street, New York.

ON THE ANGLES OF THE EDGES OF SLIDE-REST TOOLS.

[43105.]—Having been busily engaged away from home, I did not see my English Mechanics until after the publication of "D. H. G.'s" two articles in your issues of Nov. 17 and 24. Being familiar with the numerous contributions of "D. H. G." in back volumes, I should not have made any observations on the recent articles but for the fact that he has made statements of mine the occasion of rehabilitating Prof. Willis's theory of the possible value of double-cutting edges—a theory, by the way, which the Professor only expounded "in the hope that someone with the proper opportunities will be induced to make experiments upon the best form and edges of tools for different materials."

The fact on which I take my stand and justify what I have written on the subject is, that for all practical purposes, and in probably nine cases out of ten, the angle, as given in my diagrams mentioned by "D. H. G."—that is, the angle included between the top and front faces of a tool—is taken as the "cutting angle" in all machine-shops. The top rake, and the clearance, and the tool angle included between them are measured along the middle plane of the tool. And in this sense, nine tools out of ten, doing good work, will be found to be single-edged tools.

As regards the Smith and Coventry tool-points, "D. H. G.'s" remarks on p. 307 exaggerate what occurs. He speaks of the metal engaging the edge of the elliptical cutter where its decrease of acuteness may amount to 70° or 80°, or even more. Well, it may amount to 70° in a very heavy cut, but who would think of forcing a cutter nearly half its section into metal? Besides, the cutting angles would not be 70°, 80°, or 90°, because of the angular setting of the tool-point in the holder.

As regards this tool-holder, I knew it a dozen years ago, and believe that it is used by engineers more than any other type which has been ever invented; and as to Prof. Smith's remark that the cutter is apt to slip, I never noticed such slip to occur, for the grip is too powerful. The only thing is, and that is common to all tool-holders without exception, the tool-point becomes heated on heavy duty.

If the principle of double edges, so ably enunciated by Prof. Willis, had possessed any real practical advantage over the single-cutting angle, would it not have survived in the stress of keen competition? Even Prof. Willis admitted that it is convenient to consider only the angle which the upper plane of the tool makes with the line of the front angle. It is curious, too, that Prof. Willis advocated a pointed-tool in preference to a round-nosed one. Yet modern practice uses the latter in preference to the former, and the heaviest slogging is done with such tools.

The main point raised by "D. H. G." is that in the one-cutting-edge system the edge contains only a single point in which the cutting angle remains constant. That, though obvious enough, is not a matter of so much importance. For if there is one lesson more than another which machinists learn, it is that the angles of tools may vary considerably, without seriously affecting results. When a turner sets his round-pointed tool diagonally towards the work, he takes off great curling chips with ease, notwithstanding that the angles of the tool vary round the cutting section.

"D. H. G." quotes Prof. Smith, to the effect that it is not only the front edge, but the side of the edge of a tool that cuts. But the Professor, nevertheless, does not advocate the double-edged system; his work is based on the single-cutting-angle types of tools. Of the double-edged type he says distinctly: "There does not appear to be any advantage in this form," and much more to the same effect, which I need not quote (p. 159, "Cutting Tools.")

The advantage in double-edged tools, as pointed out by Prof. Willis, is, that one edge cuts the main shaving, while the other severs it cleanly. This is a point of value in hand turning. But with slide-rest tools and ample lubrication in wrought metals, the engineer roughs out more expeditiously with a round pointed tool, and smooths with a broad faced tool, the latter taking off a mere scrape. In each case he is troubled with but one cutting angle, and that is the single-cutting angle which we have in the chisel, the plane, the gouge, the axe, and myriads of other tools.

As an old reader of the "E. M." I was once familiar with "D. H. G.'s" and "O. J. L.'s" contributions on the subject of tool edges. All the same, I do not accept that system as of much practical value. I doubt not it is an extremely worthy basis on which to fashion hand tools, and tools for the lighter classes of slide-rest turning. But I do not think it has any advantages over the system based simply on the angles of front and top faces, while for heavy cutting I should deem it much inferior.

A word about myself. "D. H. G." warns the novice to distrust such books as take the "cutting angle" for the standard by which to estimate angles, and seems to class me with the writers of books who should be distrusted. It is rather inconsistent in "G. H. G." to throw mud at "books," and then give as his authorities book writers, neither one of whom was ever under the necessity of earning by the manipulation of tools, and whose knowledge, therefore, was of an academic character. In writing on tool angles, I may say, in self-justification, I have not followed books slavishly, though I know probably all that are worth knowing; but I have given with confidence angles which I have myself measured from tools which I have known to be doing good work. What I know I have learned in thirty years of work in the practice of engineering as a means of living, and I have therefore acquired the habit of bringing statements in books always to the test of shop experience. And, therefore, because I knew that the single cutting-angle is at the basis of nearly all tool formulation in the shops, I pin my my faith to it, and have illustrated it in my writings. J. H.

An electric railway line, the current for which is generated by gas-engines, is in use in Huntingdon, L.I., in the United States. The gas costs 90 cents per 1,000c.ft., and the cost of working the line comes out at 13 cents per car mile.

REPLIES TO QUERIES.

*** *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[96864.]—**Knocking in Gas-Engine.**—Many thanks to "Jack of All Trades" for his kind reply, but I am afraid the pen-steel bush will not answer in my case, for not only is the hole in rod worn oblong, but the pin is also worn. What I want to know is, how large can I make the hole, with safety, and the best way to do it. Will not swing in lathe. I shall fit with a gunmetal bush, and make a new pin. Gunmetal will not wear the pin, and a new bush can be fitted in a few minutes. Crackpot.

[96922.]—**Stylographic Ink.**—Will anyone kindly explain the reply on p. 280? Are all the ingredients to be mixed together, or do they belong to separate recipes? At any rate, please explain the order of proceeding? Are the gum, the sulphuric acid, and the gallnuts boiled together? If so, in what kind of a vessel, and how long should the boiling be continued? I think the querist is asking for what he will not get; but it may be that the reply given on p. 280 is just the thing, only unfortunately it is not quite definite. Perhaps some reader will help to elucidate? Q N.

[96930.]—**Sound.**—If this querist will say what sort of an instrument he refers to, he may obtain an answer. Is there to be any mechanical connection between two instruments, or what? I find it quite possible to "hear through a glass window or a wooden door" without any instrument at all. In fact, the sound comes rather too easily. W. H.

[96943.]—**Diving.**—This question can be answered only indefinitely; but there is information in back volumes. The actual distance to be seen through under the sea depends on the character of the water (some holds more matter in suspension than other samples), on the diver's eyesight and the state of his health, which is affected by the pressure under which he is working. For the sake of a datum, say a mile. T. L.

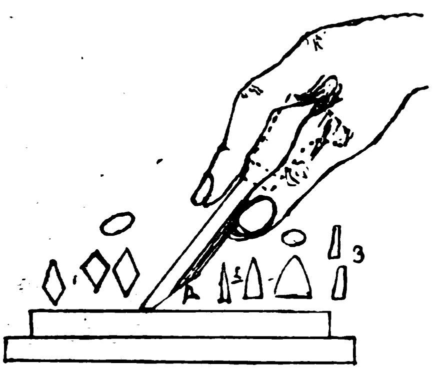
[96946.]—**Navy.**—I do not know exactly what an "assistant probationary engineer for permanent service in the Royal Navy" may mean; but it is certain that no one can be an engineer in the Navy without going through the schools and passing the examinations. The querist seems to have confused the Board of Trade exams. with the Royal Navy. There is a great difference. Essar.

[96960.]—**Carbide.**—I think, but I am not sure, that as much as 5lb. of calcium carbide can be kept within the Metropolitan District; but outside the Board of Trade regulations, which can, of course, be ascertained on application at headquarters, there are local by-laws to be noted, and they, equally of course, can be ascertained from the authorities of the respective districts. M. T.

[96985.]—**Condenser.**—Your best plan will be to get a square or round tank, and put a series of coils in it, and, taking a good size into the tank on the top just below the water-line, and from the bottom out back just above your screw, and the sea-water will circulate amongst your coils, which must be led into a tank to feed from. Of course, I do not know how you are situated, and what tools you have got; but to fit up a surface condenser proper needs money and tools, as well as a good workman to put them together. The castings for tube-plates, flanges for barrel covers, and tubes want finding, and patterns want making, and plenty of work cut out, when you may get coils fitting one inside the other to fit barrel or bore; or there are hot-water tanks all sizes to hand here that would suit your purpose. The scheme will answer, because it was patented by an old friend of mine many years ago, and is still in use on steamboats and barges. Jack of All Trades.

[97023.]—**Engraving Tools.**—The accompanying sketch will give you an idea how to sharpen them at an angle of 45° for general use. But old practical hands do not sharpen them square upon the face, but at angle right and left for right and left-handed cutting. But for your work square face, these tools are made stiff, and therefore, unless they are ground away at the long angle, A, it would require a considerable amount of exertion to sharpen them. Never touch your tool-face to wipe off burrs or the wire edge, or you will come to grief in more ways than one. When taken off the stone, job them into a piece of hard wood, to remove the wire edge. There are a few sections of tools—the diamond or lozenge shape and square are called gravers, the others (2) spitsticks; the oval sections, of which there are several, bullsticks, the chisel or square ones. (3) Scrapers. You can get any of these from Bucks, Fenns, Smith, St. John's-square, Clerkenwell, and I daresay at Melhuish, Sons, and Co., ready for use—that is, as hard as they will go. In some instances they want lowering to a very pale straw. It is very doubtful whether you would be able to make them to work

with properly, on account of getting the face up true. You can get them any section almost for parting, and all sorts of work; but if you must try your hand at making them, make them of the best steel. Heat them in a pan of charcoal-dust and salt to a cherry-red heat, and slack them right out



in some cold lard or tallow, with about 5 per cent. resin melted up with it. Let the material be clean, and keep it for hardening small tools.

JACK OF ALL TRADES.

[97100.]—**Lyddite.**—The query asks whether there is any ferrocyanide of potassium or other cyanide in lyddite, and the reply must be that its composition is kept secret. It is known, however, to be practically identical with mélinite, écrasite, and crésilite, which is probably the substance referred to as "crelinite" on p 64. M. Turpin took out a patent in this country (15089, '85) for the employment of picric acid as an explosive. It is believed to be the base of mélinite and other powerful explosives, though in its ordinary state (such as used by dyers) it is not an explosive, but burns away readily in an unconfined space without exploding; but mere contact with certain metallic oxides or salts renders it very explosive—so violently so that a small quantity will act as a detonator to any quantity of the picric acid, wet or dry, which is within reach of the detonating influence. Probably that fact is the origin of the query. It may be mentioned here that several works on high explosives have been published; but I suspect they do not contain full particulars of the substances actually used. However, there is the patent list, and much may be learned from the specifications.

S. R.

[97100.]—**Lyddite.**—The noxious gases set free on explosion of the above are not due to the presence of any cyanogen compound, but consist mainly of the poisonous carbon monoxide. T. J. LENEY.

[97101.]—**Acetylene Lamp.**—Best to unscrew if able, and soak in some such a softener as petroleum, and then rub off, if able; but it may possibly be difficult. Carbon, as a rule, being insoluble in water, acids, or alkalis.

REGENT'S PARK.

[97113.]—**Bermatine Bread.**—You can, I apprehend, work in small quantities on old lines. What do you say to aërated bread made thus:—Divide 3lb. flour into two portions; mix up the first with water, holding in solution 2oz. bicarbonate of soda; then mix the second portion with water, to which 1oz. of muriatic acid has been added. Knead each mass of dough thoroughly. When this is done, mix both portions together as rapidly as possible, form loaves, bake immediately. Bread contains no yeast, and is very wholesome. You can, if you prefer, use a baking-powder as follows:—Powdered cream tartar 30oz., bicarbonate soda 15oz., flour 6oz., all well dried, mix thoroughly, keep dry. Berme is Low German for barm or yeast, so I imagine bermaline bread means yeast bread.

REGENT'S PARK.

[97128.]—**Rate of Interest.**—It is impossible to obtain by any direct process the rate of interest yielded by a terminable security. The desired result can, however, be arrived at, to any desired degree of accuracy, by a method of successive approximation. I make the rate, taking the data exactly as given in the question (although, in all probability, the interest is payable more than once a year), to be between 3¼ and 3⅛ per cent.—more nearly 3·203 per cent. As £1 10s. has accrued for interest, a period of ⅜ of a year must have elapsed since the last interest payment was made, and, therefore, the next will fall due ⅝ of a year hence. Let i be the rate of interest *per unit* actually yielded; then the present value of 1 due a year hence is $\frac{1}{1+i} = v$ (say), and of 1 due n years hence $= v^n$; and the present value of an annuity certain of 1 per annum for n years is—

$$\frac{1 - v^n}{i} = A_{\overline{n}|} \text{ (say).}$$

(These results need not be proved here, I imagine.) Now, the price paid for the security is 108, and this has purchased the following benefits (the accrued interest of £1 10s. not being payable till the end of the current year)—viz., (1) one year's interest of £4, due ⅝ of a year hence; (2) an annuity of £4 per annum for 9 years, deferred ⅝ of a year; and (3) the redemption money (£100), due 9⅝ years hence. Therefore—

$$108 = 4v^{\frac{5}{8}} + 4v^{\frac{5}{8}} A_{\overline{9}|} + 100\, v^{9\frac{5}{8}}$$

$$27 = v^{\frac{5}{8}} [1 + A_{\overline{9}|} + 25 v^9].$$

This must now be worked out at several trial rates of interest, a simple process if a complete book of interest tables—such as Oakes'—be available. For example, try 3¼ per cent.—i.e., $i = \cdot 0325$; then the right-hand side of the equation is—

$$\begin{aligned} & \cdot 98021\,[1 + 7\,6961 + 25 \times \cdot 749876] \\ = & \cdot 98021\,[8\,6961 + 18\,7469] \\ = & \cdot 98021 \times 27\,4430 = 26{,}900, \end{aligned}$$

which shows that 3¼ per cent. is just a little too high. Similarly, 3⅛ per cent. will bring out a result of 27·166, which is a little too low. Hence the true rate is between these two rates, but a little nearer to 3¼ per cent. Interpolating between the two, we get 3·203 per cent. as approximately correct. The above equation cannot possibly be solved by any known method; but the process here adopted is by no means troublesome if interest tables can be used. A. J. H.

[97128.]—**Rate of Interest.**—

Gross price......	=	£108 0
Accrued interest..	=	1 5
Net price........	=	106 5

106·5 : 4 : : 100 : 3·7558685. This is the rate if the security could be sold for 106·5 at the end of ten years; but the querist tells us it is redeemed at par. Let us, therefore, calculate the amount of 106 5 in ten years at 3 75 per cent —

$$\begin{aligned} \log. 1\,037558 \ldots &= 0\,016012667 \\ \log. R^n &= 0\,16012667 \\ \log. 106\cdot 5 &= 2\cdot 02734961 \\ \log. M &= 2\cdot 18747628 \\ \text{Amount} &= 153\,98424 \\ \text{Less} &\quad 6\cdot 5 \\ & \quad 147\,48424 \end{aligned}$$

Now, the question is, at what rate will 106 5 amount to 147·48424 in ten years?

$$\begin{aligned} \log. 147\,48424 &= 2\cdot 1687455 \\ \log. 106\,5 &= 2\,0273496 \\ \log. R^n &= 0\cdot 1413960 \\ \log. R &= 0\cdot 0141396 \\ &= 1\cdot 033093 \\ \text{Rate} &= 3\cdot 3093 \text{ per cent.} \end{aligned}$$

—GARSDALE.

[97131.]—**Metal Polish.**—I should have thought that anyone hailing from "Owdham" would not have signed "Constant Reader" to a query which has been answered hundreds, if not thousands, of times. There is a technical difference between "polishing" and "cleaning," and there are many recipes. One favourite is the mixture of rottenstone and oil, and one for cleaning brass is "spirits of ammonia and vinegar," finishing with blotting-paper soaked in spirits of wine. Prepared chalk is useful, but to clean brass use oxalic acid, and for silver-plated instruments use jeweller's rouge, as it is not desired to remove the coat of silver. The recipes are copied from book to book, and often appear in the columns of newspapers from the pens of writers who probably never tried any experiments with them. Jeweller's rouge is not quite so low-priced as Bath-brick, but I think it is cheap. Here, then, is the recipe: Wash the articles thoroughly so as to remove all grease; hold them in a hand covered with a clean glove, and then apply jeweller's rouge (a very little) with a soft brush or very soft leather. S. R.

[97131.]—**Metal Polish.**—White vaseline 14, levigated flint 13, well-dried whiting 3, oleic acid 1. Melt vaseline with about 4oz. of lard, add the oleic acid, and stir in flint and whiting. Petroleum jelly 14, paraffin wax 2, levigated flint 11, oleic acid 1. Melt the jelly and paraffin wax, add acid, and stir in flint. Tripoli powder 28, petroleum jelly 7, oleic acid 28, paraffin wax 7, oxide of iron 7, myrobane ½. Melt the jelly and paraffin wax, add the acid, then stir in the oxide of iron and Tripoli powder, and add the myrbane, and many others.

REGENT'S PARK.

[97132.]—**Dry Inhaler.**—Menthol is dissolved by alcohol. REGENT'S PARK.

[97134.]—**Vox Humana.**—The Vox Humana in the American organ is generally a fan—that is, a stick or rod with a bit of cardboard stuck in each side—say 15in. by 1½in. broad. A wire is inserted firmly in one end of the rod, and passes into the motor-box, which is simply a box of thin wood containing a wheel of tinplate or wood. That is fixed on the windchest over a hole, and it has a valve in the top which is actuated by the stop. When the stop is pulled out, the air rushes past the wheel to the bellows, and the wheel being attached to the cardboard fan, causes that to revolve rapidly—thus producing a wavy atmosphere in the inside of the case, and therefore wavy sounds from the reeds. It will be understood that the bearings of this little affair must be "nice," to prevent any rattle. ORGANON.

[97135.]—**Expansion Rate of Metals.**—Aluminium: Centigrade 0000231, Fahr. 0000130, co-efficient of linear expansion Austen Roberts. Chaney gives for 1° Fahr. 0 00001234, for 1° Centigrade 0·00002221. See book issued by Pittsburgh, Reduction Co. on "Aluminium and Alloys, &c.," 1898, second edition. As to iron expansion, between 32° (0 Centigrade) and 202 (100 Centigrade 0 001220 to 0 001235.

REGENT'S PARK.

[97137.]—**Grammaphone.**—In reply to "T. M. C.," I have counted the teeth in wheels and pinions as accurately as I can, and the following is the result:—Large wheel (Fig. 33, p. 256), 150 teeth; pinion underneath ditto, 28; second largest wheel (C, Fig. 31, p. 255), 63; pinion above ditto, 20; smallest wheel (B, Fig. 31), 58; pinion beneath ditto, 18; spring wheel (D, Fig. 32, p. 255), 65; ratchet attached to ditto, 10; flywheel pinion (P, Fig. 26, p. 254), 19. I hope this will give him the information that he requires.

R. A. R. BENNETT.

[97138.]—**Polishing Specula.**—Spend no more time in polishing, but return at once to the fine grinding. The roughness you can distinguish through the magnifying glass has been left by the coarser emery, and you have proceeded to polish before sufficiently fining with elutriated emery. Contrary to the opinion expressed in your query, rapid polishing must produce heat, and will inevitable destroy the curve left by the fine emery grinding. I much prefer polishing by prepared pitch polisher; but, on the other hand, Dr. Blacklock, a late former correspondent to this journal, rather favoured paper polishing. Work with your finer emeries until the mirror seems on the point of transparency, and the task of polishing with pitch, instead of being a labour, will then be a work of skill and scientific interest.

Northants. FRANK H. WRIGHT.

[97140.]—**Dynamo.**—For so small a power the most suitable dynamo would certainly be a little overtype Siemens H armature dynamo. Diameter of armature, which should be laminated, 2in.; length 2in. Massive pole-pieces, with F.M. cores 2in. by ¾in. in section and about 2in. wiring space. If the armature be wound with No. 20, and the field-magnets with No. 22, shunt connected, you will have an efficient machine, well under control of your engine. S. BOTTONE.

[97141.]—**Glass-Blowing.**—The best book on the subject for amateurs is by T. Bolas, "Glass-Blowing," price 2s. 6d., published by Dawbarn and Ward. It gives full instructions for tube-joining, thermometer making, and fancy work in glass.

West Didsbury. M. COLE.

[97142.]—**Telescope.**—The following is an easy and very fair method of finding whether the object-glass of a refracting telescope is square with the axis of the tube:—The correcting (flint) lens of the o.g. is a double-concave, and therefore the surface nearer the eye-tube will throw back an image of a light if held at a certain point distant from it as close as possible to the observer's right eye. In a dark room lay the telescope level at a convenient height. Keep the cover over your object-glass, and remove the eyepiece tube. Hold the candle as already directed, and presently the observer will find a position in which the inner concavity of the o.g. will be illuminated all over. This is the focal point, and if your eye is central to the axis of the tube the glass is correctly placed. If, on the other hand, no such reflection appears, the observer may take it for granted that his o.g. is not square with the axis of the tube, and he should take steps to remedy it. In answer to the second part of his query, "Algol" can probably refer back to last year's volume of the "E.M." to find a description of what is called "The Sirius" telescopic stand—a simple and inexpensive arrangement that might probably suit him.

Northants. FRANK H. WRIGHT.

[97143.]—**Induction Coil.**—TO MR. BOTTONE.—Wire resistances for shocking coils are eminently unsuitable, because so much is wanted. One square inch of your skin presents a resistance of about 4,000 ohms. So, if you feel a severe shock from the coil without a resistance, you would have to insert a resistance of 4,000 ohms to halve its intensity, and in the case of No. 42 platinoid this would mean about ¼lb. Where could you stow it? The plan is altogether bad. You should have wound your secondary in 16 separate sections, and brought out the ends to the studs, thus: ⌒⌒⌒⌒ &c. If the

iron core is good and the primary well wound, it does not require a specially delicate spring on the contact-breaker to work with even one dry cell. Water regulators are excellent for secondary coils, if properly made. S. Bottone.

[97145.]—**Ampmeter.**—Make a sucking solenoid about 2in. long, wound with two layers No. 14 d.c.c. copper wire. Connect the ends of this wire to the terminals. Arrange a thin piece of soft sheet-iron, pointed at one end, and about ½in. wide at the other, so that it can swing in the inside of solenoid, without touching the sides. This must be suspended by pivoted arm from a bracket. A prolongation of this arm carries a light pointer, which travels over a cardboard or metal quadrant, on which the ampères are marked. The instrument can then be graded, either by being put in circuit with another ammeter, or with a battery giving a known current. See my book "Electrical Instrument-Making for Amateurs" for fuller instructions, under the heading "Solenoidal Ammeter." S. Bottone.

[97149.] — **Manchester Dynamo.** — To Mr. Bottone.—In going through your data, it strikes me that either your figures have been given wrongly, or else that you have about twice as much wire on the armature as needed. 5lb. No. 17 wire would be about 180 yards, of which nearly 90 would be active. This is greatly in excess of the requirements, and, besides, throws the iron core so far away from the fields. In our armatures of this size we put on about 2lb. No. 20 = 160 yards, and get 50v. 8a. quite easily. It is quite possible that you may have a false coil on the armature. The amount of wire on the field-magnets, 22lb, though not disproportionate in a large machine made of very soft iron, may be too much in your case. Try the effect of putting the F.M. wires in parallel, and report results before proceeding to rewind the armature. S. Bottone.

[97150.] — **Wireless Te'ephony.** — Erect two equilateral triangles of insulated wire, each 70ft. in the sides; one at the receiving, and one at the sending station. At the apex of the latter place a microphone in connection with a coil and battery. At the apex of the former, connect the telephone. S. Bottone.

[97151.] —**Bone Bearings.**— In reference to answers to above my experiences may be useful. I acted on the suggestions of our old and respected correspondent "Jack of All Trades," who wrote about bone bearings some time ago in the "E. M." I purchased a leg-of-beef bone, and turned a collar for my 6in. centre foot-lathe, as I had previous difficulty with steel collar. After giving the bone collar a fair trial, I had to discard it, and replace steel collar in lathe; the result of bone bearing was that, in spite of large amount of lubricating oil, my lathe-spindle got exceedingly hot; lathe also ran very heavy. I ran lathe at about 1,200 to 1,800 revolutions a minute. I think our old correspondent was in error in the following manner. It is a well known fact that steel a few years ago was of a far different nature than the steel is at the present time, being made under a different process; and probably the lathe that our friend had to repair, the spindle was of a good-quality steel, and run well in a bone bearing. I have had some experience in paying for lathe repairs, and I may state that there is a difficulty in getting a lathe-collar or spindle properly hardened. I had my lathe fitted with best steel bearings, and hardened the collar, back-centre, and spindle myself. Result: lathe has been running nine hours a day for the last two years by foot, without any cost for repairs, for turning bone. Ordinary wood-turning tools would do if of a good quality, about ½in. ground bevel. For burnishing, try a piece of leather, rubbing quickly, or running as a buff. I must apologise to our respected friend "Jack of All Trades" for answering query addressed to him, for I feel sure he has answered to the best of his abilities, and trust that he may be long spared to answer any of "ours" in "E. M." Hardwood Turner.

[97151.]—**Oil-Engine.**—The foundation suitable for a ½ oil-engine is best made of bricks built up with cement, and the middle part filled in with concrete. The holding-down bolts should be bedded in holes cut in the brickwork, and filled in with liquid cement. Leave it to set about two days before running engine. The size would be about 58in. by 30in. It would be advisable to make dynamo-bed in the same manner as engine, bedding the belt-tightening rails in liquid cement. A 1in. leather belt is quite strong enough for dynamo, but should be flexible, and the joint well made, so as to pass easily round the dynamo pulley; otherwise, the voltage will jump each time the joint passes round the pulley. Ignition Tube.

[97152.]—**Coherer.**—Such a coherer will work, though it is not of the best form. (See my many letters on this subject in back numbers.) One-eighth of an inch will be ample between the ends of the wires. Do not jam the filings between the points; let them lie loosely. A 6in. spark-coil would transmit for nearly 10 miles. You may either screw up contact-breaker tight, or leave it in its usual position; but in either case you must use a tapping-key. My book will not be out till January; but there is Kerr's and Oliver Lodge's. S. Bottone.

[97154.]—**Bone Bearings.**—In the "seventies" I laid out a deal of money, intending to make this one of my specialities in supplying of these for various purposes; but being haunted by a demon-possessed individual, until human nature could stand it no longer—the same had haunted me for years—I found that if I did not make tracks, that it must either end in lunatic asylum or on a rope around my neck, so I made tracks. A month after I made my appearance again, to find matters worse, and upon looking things up again worse still, for the demon had made away with materials that I had prepared, and many things that were intrusted to me for repairs, for about one-fortieth of the cost, for the sake of drink, the whereabouts of which I never could find out. A party whom I had assisted in more than one way robbed me of my tools, and that broke my back. 1. No, it is not likely to cut a ring around the centre of bush, and a hole into it. 2. Any good sound bones, as marrow-bones, sheep, oxen, horse, and elephants', and any of the sound bone-shanks or marrow. Two of the shanks are flat, and two round; any that look like ivory. The one that I saw, and believe could have been traced for 200 years, was running in the knuckle of a ham-bone. 3. I should think that they would do very well in a wet place. I should not hesitate to use them. 4. The cohesion of African oak being 17·200lb. per square inch, bone would at least double that. 5. Yes, if lubricated properly, I have not the least doubt but that they stand any speed; why not? Boxwood steps have been in use in silk and cotton mills to advantage. 6. There is no reason why they should not be fit for gas, oil, or steam-engines, or rotary engines, and all dynamos and electric motors, connecting-rods, and slides, as well as gland-packing. The cause of their being everlasting is their more pliable, tough, elastic composition, as witness your own carcase. Good bone was no more porous than ivory. Bone does not wear down if the bearings, or rathermore journals, are turned true and burnished. 8. No, bone is not self-lubricating. 9. What do you want to burnish bone for? There is no reason for doing so, and it is not very likely. Just think for a moment what would be the result. The oil would decidedly render it loose and laminated. If you mean what is used to polish bone or ivory: whiting, well washed, and methylated spirit. 9. A species of gravers are the best tools, the faces of which are ground up true and polished to a face. The front may be ground any angle from 80° to 45°. Bone, like Babbitt's metal, should be put into a shell, or the recess made in the article, and the bone bush built in as shown at Fig. 3, query 97696, p. 343, Nov. 24, 1899. Jack of All Trades.

[97155.]—**Catch Question.** — "Damon" can sell five apples for 2d. only when he takes three from the cheap lot, and puts them with two from the dear lot. This he can do only ten times, for then he will have used up all the cheap apples, but will still have 10 of the dear ones, which, of course, he cannot sell at the rate of five for 2d. Arithmos.

[97155.]—**Catch Question.**—Three for a penny = $\frac{1}{3}$ of a penny each; two for a penny = $\frac{1}{2}$ of a penny each. Adding together $\frac{1}{3}$ and $\frac{1}{2}$, we get $\frac{5}{6}$ of a penny as the value of two articles. Now, five articles for 2d. = $\frac{2}{5}$ of a penny each, or $\frac{4}{5}$ of a penny for two. We now compare $\frac{5}{6}$ or $\frac{25}{30}$ with $\frac{4}{5}$ or $\frac{24}{30}$, and find things are not what they seem. Quite a nice little catch. Almost as good as the hen and a half that laid the egg and a half. T. J. Leney.

[97155.]—**Catch Question.**—If you take equal numbers of an article at one halfpenny and one-third of a penny each, the average price is twenty-five sixtieths of a penny. At five for twopence, the price is twenty-four sixtieths. R. B.

[97155.]—**Catch Question.**—The reason is that in the question as put the numbers 3, 2, and 5 are the denominators of fractions, and must not be added together. If we put half a crown instead of one penny in the question, and then reduce to lowest terms, this becomes instantly apparent.
Oystermouth. Scorpia.

[97155.] — **Catch Question.** — The reason is twofold; (1) As to the value of the articles. Because 30 articles at three a penny are worth 10d., and 30 at two a penny are worth 15d., total 25d., or 2s. 1d., whilst 60 articles at 5 for twopence, or 2½ for a penny, are worth only 2s. Thus: 3)30(10, and 2)30(15 = 25, or 2s. 1d., 2½)60(24, 2s. exactly. (2) As to the numbers themselves, irrespective of values, $30 \div 3 + 30 \div 2 = 25$, while $60 \div \frac{5}{2} = 24$; evidently not the same. S. Bottone.

[97155.]—**Catch Question.**—There are three ways of looking at this old catch; but probably the following will reveal the precise source of its "catchiness" best. Suppose the 60 articles to be arranged in 12 twopenny groups where each rate of sale alike produces two shillings. There will then be 36 articles included in the three-a-penny lots and 24 in the two-a-penny. The question, however, stipulates that 30 only shall be sold at each of these rates. Hence six of the three-a-penny articles, which produce 2d., must be transferred to the two-a-penny lots, which produce 3d., or a gain of one penny. Again, we may equalise the prices thus—

$$\left.\begin{array}{l} 30 \text{ at } \tfrac{1}{3}\text{d.} = 10 \text{ at 1d.} \\ 30 \text{ at } \tfrac{1}{2}\text{d.} = 15 \text{ at 1d.} \end{array}\right\} = 25 \text{ at 1d.}$$
$$60 \text{ at } \tfrac{2}{5}\text{d.} = 12 \text{ at 2d.} \quad = 24 \text{ at 1d.}$$

Hence there is an additional 1d. article sold by the first arrangement. Lastly, we may express each article at fixed rates—

$$\left.\begin{array}{l} 3 \text{ a penny} = 1 \text{ at } \tfrac{1}{3}\text{d.} \\ 2 \quad \text{do.} \quad = 1 \text{ at } \tfrac{1}{2}\text{d.} \end{array}\right\} = 2 \text{ at } (\tfrac{1}{3}\text{d.} + \tfrac{1}{2}\text{d.})$$
$$= 2 \text{ at } \tfrac{5}{6}\text{d.} = 1 \text{ at } \tfrac{5}{12}\text{d. or } \tfrac{25}{60}\text{d.}$$
$$5 \text{ for twopence} = 1 \text{ for } \tfrac{2}{5} = 1 \text{ for } \tfrac{24}{60}\text{d.}$$

Thus the second rate is $\frac{1}{60}$d. cheaper than the first, and therefore produces 1d. less.
West Norwood. Henry T. Burgess.

[97158.]—**Bichloride Mercury Disinfectant.**—Should say there was no fear of injury in its use. Regent's Park.

[97165.]—**Drill Makeshift.**—The best thing for "Impatient" to do, will be to buy a breast drill. I use one by the Millers Falls Co., and a few twist drills size of holes required. He will find this to suit small jobs, if he does not want to go in for a bench drilling machine, which would come in rather expensive. J. A. C.

[97165.]—**Drill Makeshift.**—Drill is probably soft; see that drill is well hardened, and cutting-edges are properly sharpened, and see that drill is a good fit in brace or spindle. Hardwood Turner.

[97166.]—**Chromic Battery without Acid.**—Pure chromic acid contains no sulphuric acid; some commercial samples do; but even these, not in sufficient quantity to render them of any use in a battery without the addition of a considerable quantity of sulphuric acid. Your only way to prevent the rapid consumption of the zinc in a Fuller cell is to dry the porous pot thoroughly, and then to paint it all over, except one narrow strip, ½in. wide up one side, with hot melted paraffin wax. S. Bottone.

[97170.]—**Grammaphone Records.**—Will not the article on p. 321 of the last volume (LXIX.) give you the information you want? R. A. R. Bennett.

[97172.]—**Holtz Machine.**—To Mr. Bottone. (1) About 3in. (2) Yes, and very uncertain in action. (3) Yes, by taking one electrode from the Wimshurst to one of the "windows" of the Holtz. (4) No. See my book on "Radiography" for description of the best type of machine for this purpose. S. Bottone.

[97173.]—**Pigeon Post Photos.**—I made some of those for a bazaar by the ordinary dry-plate process. First make a negative, then a good positive transparency as for a lantern slide. Soak in acid and water till the film floats off. Then float it over a plate slightly smeared with vaseline, to prevent it sticking. Strengthen when dry with a coat of collodion, then pull off and wipe off any vaseline that may come with it.
West Didsbury. M. Cole.

[97176.]—**Cement for Vulcanite.**—This universal cement may be worth trial. Boiled linseed oil 20, gelatine size 20, slaked lime 15, crude turps 5, alum 5, acetic acid 5. Melt size in acetic acid. Add alum, then slaked lime, then turps and boiled oil. Mix thoroughly, and keep in well-stoppered bottles. Good for wood, glass, cardboard, porcelain, &c. Regent's Park.

[97178.]—**Joint and Piston Packing.**—The joint for cylinder covers is made by cutting an asbestos millboard ring the same size as flange on cylinder end, making small holes for the bolts to come through, and screwing up tight. I suppose the cylinder and cover to have faced joints. You will find soapstone and asbestos packing as good as anything for packing piston-rods. J. A. C.

[97179.]—**Explosives.**—The safest way would be to use the small paper caps used with toy pistols. You could use two or three to get noise enough.
West Didsbury. M. Cole.

[97181.]—**Giddiness.**—This may be due to a variety of causes, amongst them cerebral, cardiac, or aural trouble; aural trouble is generally accompanied with deafness. Overwork of the brain is also a cause, so also is a deranged stomach. The querist had better see a reliable medical practitioner whom he knows by repute to be fairly straightforward as the world goes nowadays, and get him to find out the cause—that is, if he can. It is hardly possible that anyone in these columns could suggest a remedy likely to be of any use without knowing the cause. T. J. Leney.

[97183.]—**Painting on Silk or Satin.**—In oils:—Tightly stretch material, and thin colours with turpentine, but not so to make them run. Use

only enough colour to hide material underneath, and blend the lights into dark shadows with help of a dry brush. If when first coat is dry material shows through, apply a second, worked in like first, then bring out stamens of flowers and markings of leaves sharply; throw up well by working in deep shadows behind or near them, but attempt no great amount of shading. Dark flowers require a good deal of working up, light do not, and therefore preferable in this kind of work. Use wooden rest to keep hand from touching wet paint while work in progress. Take a bar of wood 2in. wide, raised at its extremities by feet 2in. high, length variable, according to size of painting, which it should just clear. Place it across, and steady the hand by resting upon it while working. When painting is quite dry (four or five days) varnish with white spirit varnish, if it dries dead and colourless, but if bright omit this last. In water colours: Stretch evenly, then take 1oz. Nelson's gelatine, melt in tall gallipot just covered with cold; leave for one hour, pour off cold water, add pint of boiling water; stir, dissolve quickly, run through coarse muslin to strain, and whilst hot apply to silk. Take sponge, well clean face, dip into hot gelatine, thoroughly wash over surface, not too wet; rub mixture well in, leave no place untouched. Rub with piece of soft silk and leave stretched till perfectly dry, then rearrange it if it requires restretching. Same mixture can be applied to satin, but as every mark shows great care is required. Arrange design. Draw this out on a sheet of paper; if a fan, be careful that the largest flowers, &c., are not stretched in so that they come on ribs of fan mount, &c. Trace outline of the design on to silk or satin. Use tracing paper, red carbonised paper, and a fine knitting-needle; clean carbon paper before use. Do not press on it, as all marks show. Painting done in two ways. Easiest is by mixing Chinese white with other colours to turn into body colours; second is by simple water-colour, working up colours patiently, last tints and higher lights added in body colour, but chief painting in ordinary moists. To paint with body colour:—Materials: Chinese white in bottles, ordinary moist colours, ox gall, veloutine, red sable brushes, palette; distilled water, to which a little sugar is added; spare pieces, to try effect of colours. Always put colour on palette before mixing it with white or other colours, and keep that left in pans perfectly clean, or shades become dirty. Be careful that Chinese white is not too dry, as it cakes and rubs off. Add veloutine to it before use; rub well up with palette-knife. Commence by laying coat of C. white mixed with V. over whole design; lay on rather fully, without streakiness. Thin with turpentine if too thick, and whilst wet colour required tints into it. Lay colours over white ground as even tints; do not attempt to shade. Do not apply to design a shade not tested on spare silk or satin. Body colour on satin allows of less shading than on silk. White satin requires no ground of Chinese white. These data are not all in book—viz., B. C. Saward on "Decorative Painting," published by L. Upcott Gill. That gives on various textiles, pottery and porcelain; paper, vellum, and leather; glass and wood; stone, metal, &c.
REGENT'S PARK.

[97185.]—**Bookbinding.**—You can never get these equal to new again, but a great deal can be done with a hot burnisher, as used by bootmakers for polishing the soles of boots. A little white of egg as a dressing will help.
West Didsbury. M. COLE.

IT is said that only about one-seventh of the glass used in this country for ordinary purposes is of British manufacture.

TELEPHONIC communication between St. Petersburg and Moscow is obtained by a line 412 miles long. It is said to be the longest single line in Europe.

A Gigantic Megaphone.—An enormous megaphone has been erected at Faulkner's Island, Conn., on the Government lighthouse reservation, for testing a new system of fog signals. The megaphone is 17ft. long, and 7ft. diameter at the mouth. Attached to it is a 1½in. steam siren. The whole contrivance is mounted on a circular platform 28ft. in diameter, so that it can be revolved to any point of the compass. Different signals may be made for each point of the compass. The object of the invention is to throw the sound-waves in a certain direction to the exclusion of any other direction, so that any vessel approaching the signalling-station in a fog shall hear only the sound which is given when the megaphone is pointed directly at it. That is to say, if the signal means north, the fog-signal must be due north of the vessel, or those on the latter could not hear that particular signal. The instrument has been tested, and it was found that the sound could be heard 10 miles away when the observer was standing in a line with the axis of the megaphone; but nothing could be heard of the sounds sent to other points of the compass when at a distance of a mile or more from the instrument.—*Scientific American.*

UNANSWERED QUERIES.

The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered, are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.

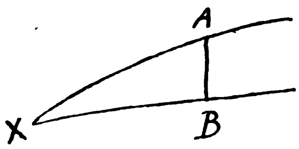
QUERIES.

[97187.]—**Calculation of Sun's True Bearing and Altitude.**—I should be obliged for explanation of these calculations, latitude and sun's declination being known. The solutions of both quantities are got, I



presume, from a spherical triangle, in which X B is the line of the horizon and X A the path of the sun on any given day across the sky. The point X will be the intersection of horizon and sun's path, and the side X A will be got from the hour angle. Particulars of calculating this hour angle will be very acceptable, as it involves that of time of sunrise. Having got X A, the angle at X is got from sun's altitude at noon, I suppose, and, of course, B is a right angle. Are these the two quantities used for the complete solution of the triangle and determination of azimuth B X and altitude B A at any given time?—FLEUR-DE-LYS.

[97188.]—**Asbestos Packing for Incubator.**—I am making an incubator on Hearson's principle, and wish to pack that part of the flue which is in the lamp-box with asbestos for heat-retaining purposes. Will asbestos powder answer my requirements as efficiently as the usual asbestos packing, since I find it can be purchased at about one-fifth the price of the latter? An answer will much oblige.—A. DICKENSON.

[97189.]—**Razor Sharpening.**—Will someone tell me the proper way to work a dull razor up to shave easy? Also state what kind of grindstone, oil-stone, and strop for getting up full hollow-ground and half hollow-ground razors.—SHAVER.

[97190.]—**Launch Boiler.**—I have a small vertical launch boiler, with 19 vertical tubes. Up to a few months ago it made steam very well; but now I cannot raise above 5lb. or 10lb. If I do manage to get 50lb. or so it works down very quickly. What is likely to be the cause? No alterations have been made.—W. J. R. BELL.

[97191.]—**Disinfectant.**—A firm of chemists of repute advertise as a disinfectant pellets of nitrate of lead to be dissolved in water which is to be added to other water in which common salt is dissolved. In what way does this mixture act as a disinfectant? Is it by the evolution of chlorine from the salt (chloride of sodium)?—ROTOS.

[97192.]—**Dynamo.**—I have a dynamo made by Spagnoletti and Crookes giving 10 ampères at 100 volts, speed 1,650. I wish to rewind this to give 10 volts and 40 ampères. The size of armature over the wire now on is 5¼in. and the length 5½in.; the commutator is 3in. diam., and has 30 sections in it. Will some of your readers tell me the size of wire required for both the armature and field, and number of turns? Also, what speed would it require to run? It can be arranged for any speed suitable, the slower the better.—E. JONES.

[97193.]—**The Colouring of Lantern Slides.**—In the "E.M." of Nov. 24 appeared an extract from the *British Journal of Photography* under above heading. Will some of "ours" who have had experience with aniline colours give their experience and say if they can be used on the print-out lantern plates, such as Paget's? And also give details of articles required for a person beginning, and who has had only little experience. A reference to a good work or articles in back numbers of the "E.M." would greatly oblige.—J. F. H.

[97194.]—**To Mr. Bottone.**—Is the Carsak cell you described in last week's "E.M." non-polarising, or how long will it last, taking the full current from it?—ELECTRO.

[97195.]—**Sizes of Wire.**—Will Mr. Bottone kindly tell me if No. 14 wire for the primary and No. 24 for the secondary will answer the same purpose as No. 24 primary and No. 36 secondary in shocking coil, as directions in your book?—F. J. BUXTON.

[97196.]—**Science and Art Department Certificates.**—I am desirous of obtaining the elementary and advanced certificates of the Science and Art Department for knowledge in astronomy, chemistry, and electricity. Can any reader of "Ours" tell me how best to proceed? Where could I get examined? I do not attend any evening science class, as I cannot be absent from home, but I teach myself from book and experiments. Any information bearing on this will oblige.—LUX.

[97197.]—**Change-wheels.**—Could any reader tell me how to get sizes of a set of change-wheels? I have got a screw-cutting lathe, but no wheels. How must I measure to get the wheels right?—W. J. ROGERS.

[97198.]—**Screw Gear-Wheels.**—Will "Jack of All Trades," or some other able reader, say if screw gear-wheels for gas-engines 10 and 20 teeth can be cut in a lathe with a milling cutter thus: by fixing vertical slide on the top slide and set the top slide at a sufficient angle, then by having a bearing on the vertical slide with a spindle through it, with a pattern wheel at one end and a blank wheel to be cut at the other, and a fixed tooth on the saddle, so that when the top slide is fed up by hand would it give the proper swerve needed? I am afraid the screw-cutting wheel would not stand the strain to cut such a quick thread as would be needed in the 10-teeth wheel, which would be (?) diameter and 1½in. across the face, of course. Place the milling cutter on mandrel between lathe-centres. Also, would more than one cutter be needed?—J. A. C.

[97199.]—**To Mr. Bottone.**—1. Is it necessary for iron rods to be continued down pole, or about 10ft. from top, and lead in with leading-in wire? 2. How is the transmitting coil prevented from effecting the home coherer as well as the distant one? 3. How are the waves directed to one station alone from a central station which can communicate with two others, so that both shall not be affected at once?—E. H. K.

[97200.]—**Feed-Pumps of Steam Launch.**—I have a small steam launch driven by a compound condensing-engine. The air and feed-pumps are driven by gut bands off the main shaft. As these are constantly breaking, I shall be glad if anyone will please tell me if it will be best to drive the pumps by a chain or by an eccentric off the main shaft. At present the pumps work at half the speed of the engine, so that if I drive by the means of an eccentric the pumps will have to work at the same speed as the engines, but to get over this will have to work at half their stroke. Will this be correct? At the same time, I shall be glad to know if a chain can be got that will work without noise, and what chain?—E. J. C.

[97201.]—**Dross from Type Metal.**—I have a large quantity that I wish to get back into bar metal. Would any reader inform me the best way to do this, and kind of furnace required? I have steam-power, so could easily get a blast.—DROSS.

[97202.]—**Gas-Engine Piston-Rings.**—I should be very much obliged if any of your readers would be kind enough to illustrate and explain how a gas-engine piston-ring is turned, as I have seen one turned in rather a funny style, and find that the engine blows a fairly good quantity of exploded gas through or between the piston and the cylinder, and causes no very pleasant smell.—POOCHO.

[97203.]—**Ivory Dust.**—I have a quantity of ivory dust, and I would like to use it if possible. Could any reader give me particulars of any process of moulding it into small objects to be as hard as possible?—T. V.

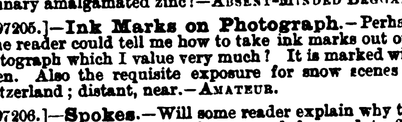
[97204.]—**Daniell Battery.**—(1) Is a gravity Daniell battery suitable for lighting a photographic Ruby lamp of about 2½c.p.? (2) What is the voltage of each of these cells, and (3) internal resistance? (4) How is an alloy of zinc and mercury made, as it is recommended in place of ordinary amalgamated zinc?—ABSENT-MINDED BEGGAR.

[97205.]—**Ink Marks on Photograph.**—Perhaps some reader could tell me how to take ink marks out of a photograph which I value very much? It is marked with a pen. Also the requisite exposure for snow scenes in Switzerland; distant, near.—AMATEUR.

[97206.]—**Spokes.**—Will some reader explain why the spokes of some wheels, which are used for road traffic, and especially those of coal, rubbish, and such carts, are dished in—i.e., the rim and spokes are not in one plane? Is there any scientific reason for this?—H. N. N.

[97207.]—**Multiple-Plate Wimshurst.**—I would feel greatly obliged if Mr. Wimshurst or Mr. Bottone would kindly state if a 12-plate Wimshurst with glass plates 28in. diameter would act satisfactorily if the trunnions were made of steel tubes instead of wood (as in the 36in. plate machine made by Messrs. Watson, of London)? Would the presence of so much metal so near the plates affect the efficiency of the machine?—T. M. C.

[97208.]—**Voltage.**—I charged my 8-volt accumulator from works electric light circuit, which runs at 80 volts, and connected as per diagram; but I cannot understand



the following. I shall be glad if someone will explain. Why should the voltmeter B only register 10·5 volts when voltmeter A registers 80 volts. I switched current off; then B registered 10 volts, which I can understand. The ammeter registered 0·7 amp.—VOLTAGE.

[97209.]—**Incandescence.**—I want to heat a platinum wire of 1 millimètre diameter and 1ft. long to white heat, near fusion point, for about half an hour at a time. Wire is coiled into shape of a spiral. No dynamo available. What kind and size of battery would be most suitable? How is the problem to be calculated? Also

for other metal wires? Would Mr. Bottone or other specialist oblige?—A. S.

[97210.]—**Steel-Facing Copper Plates.**—Would Mr. Bottone or other kind reader advise me on the following subjects? I want to steel-face copper printing-plates (size 20in. and under). I have available for the purpose a Gramme dynamo (series wound) capable of giving a current of 20 amps. at 50 volts when making 900 revolutions per minute. Should be glad of answers to the following questions:—1. What is the best voltage for this work, and how can I obtain this with my machine, using one depositing vat only? 2. How to control the intensity of current with varying surface of copper in depositing vat? If this has to be done with a variable resistance, please give particulars how to construct same, and sketch showing connections. 3. What is the best solution to be employed? In preliminary experiments I have found great difficulty in depositing a film of sufficient thickness of white metal, the plates after a while becoming covered with a yellow or black film respectively, when one or the other of two solutions was employed. Is this due to the solution, or the intensity of the current employed? If to the latter, please state what amount of current should be used, and the best and simplest means to adopt for measuring same?—TRINACRIA.

[97211.]—**Cockroaches.**—I have a kitchen infested with cockroaches. I am building a new one. Can I set the range with any particular cement or poison therein to prevent this nuisance?—CHESTER.

[97212.]—**Molybdenite.**—I should esteem it a great favour if any of your well-informed metallurgists would kindly tell me the value of this mineral in the market, and also the best market for it. I understand it is becoming extensively used in the arts and sciences. I am told by a friend that molybdenum constitutes one of the metals forming some of the valuable alloys on the market whose composition is for the present kept secret. If any of "ours" should choose to enter into correspondence with me touching it—as I am part owner of a deposit of it—my address may be found in the "Address" Column of this journal.—THIRTY YEARS' SUBSCRIBER.

[97213.]—**Chaff Cutting.**—Can any reader kindly give me the required information? I have a chaff-cutter which I desire to be worked by power. It is in a loft 40 yards from 8H.P. steam-engine. Is it possible to work the chaff-cutter by this engine to advantage, notwithstanding the distance between the two? If so, how? Perhaps it would be cheaper to buy a small oil or gas engine to drive it. The chaff-cutter must be kept where it is.—REDBUN.

[97214.]—**Softening Brass.**—Where can information be obtained as to the methods of softening and hardening brass, both sheet and wire? There is plenty of information to be got as regards softening and tempering iron and steel; but if brass cannot be tempered, how are brass springs made? I have consulted Holtzapffel and many other books in vain on these points; but the principal reason for my question is that some time ago I found much difficulty in fastening some thin brass sectors on to Wimshurst machine I was making, owing to the softness of the metal, while some samples I obtained from the manufacturers being hard and springy, and perfectly flat, could be easily attached without rising here and there, as my own did. Any hints or information on these points will be welcome?—A. C. T.

[97215.]—**Hektograph Stains.**—Can anyone tell me what will remove hektograph inkstains from a mahogany table. I have tried hot water, but cannot get the stain out. Also, white stains caused by leaving glasses with hot water on the table?—JACK.

[97216.]—**Grammaphone.**—What is the largest size of the records to be had? Those I have seen are about 7in. across.—GRAMMY.

[97217.]—**Gravitation Problem.**—I have been informed that there are cases on record of a balloon descending so rapidly as to pass the ballast thrown from itself. Will any scientific reader kindly inform whether this is a fact, and, if so, what is the reason for it? I thought that gravity affected all falling bodies equally. —NEWTON.

[97218.]—**Potash Making.**—Will any reader of this paper kindly inform me what is the nature of vessels used in potash-making, and which is the best practical book adapted for the same?—AN OLD GREEK READER.

[97219.]—**Rope Drive.**—To get a silent drive from an electric motor, I use a rope 1¼in. circumference running on a pair of pulleys with five grooves each and a guide-pulley, the single turn of rope 28ft. long running round the five grooves and over the guide-pulley. As the motor-pulley is only about 3½in. diameter, the rope has to be very flexible, so I use collars, but this gives much trouble from continual stretching. Can anyone recommend a flexible rope or cord that can be spliced or joined, and that will not go on stretching continually? Gut-band seems rather stiff, and the hook-and-eye joint is liable to come off. There is rather a heavy pull on the rope.—J. BROWN, Belfast.

[97220.]—**To Mr. Bottone.**—Will you kindly inform me of a book that will assist in calculating the sizes of cables, wires, and fuses to carry current for from one to any number of lamps?—A LEARNER.

[97221.]—**Telectroscope.**—As there seems to be some doubt whether Szczepanik has invented a machine for "seeing by wire" or not, will someone who knows for certain kindly say where a description can be seen? Or, if patented in England, what number is it, as I am certain there are scores beside myself who would be glad to see such a much-sought-for machine?—R. W. S.

[97222.]—**Eros.**—The elements of the orbit of this planet, recently calculated by Hans Osten from over 200 observations, make the planet's period and distance a little less. Has any amended value of its eccentricity (0·23) of a year ago been given?—GARSDALE.

[97223.]—**Staining Deal Cabinet.**—I have a deal cabinet stained walnut and varnished. I wish to restain and polish it. What would be the best method of removing the old varnish, and would you recommend a good polish?—W. H. COX.

[97224.]—**Curb Chain.**—Could some reader in the jewelry trade inform me how to make the links of a curb pattern chain (gold)? If a special tool is required, a short description would greatly oblige.—B. CARLISLE.

[97225.]—**Acetylene Burners.**—I am making an acetylene gas plant for my lantern (4in. condensers). (1) How can I obtain suitable burners? (2) How many should I require? (3) What should be their relative positions?—FISHTAIL.

[97226.]—**Condenser.**—Will Mr. Bottone kindly say about how many square inches of tinfoil it takes to make a condenser of one micro-farrad capacity? Also, what size wire, two layers, to magnetise an iron wire core 15in. long by 1½in. diameter, battery to be used with same 8 volts 25 amp. hours?—A. F. G.

[97227.]—**Wimshurst.**—I have read with interest the replies of "J. W." to various correspondents on Wimshurst machines, and also the letters he has contributed on the same subject. I am thinking of constructing a fairly large machine with about ten 32in. plates, and should be glad of information on a few points. (1) Is glass equal in any way (except, of course, its liability to breakage) to ebonite? (2) Would it be advantageous to have the driven pulleys made of ebonite instead of wood? (3) What material is best for the neutralising brushes, excepting palladium-iridium alloy? (4) Is tinfoil as good for sectors as brass or copper, with a slight projection pressed in? (5) What is about the most suitable thickness of tinfoil for sectors? (6) What material is best to form the insulating supports for collectors? (7) What precautions are necessary to prevent reversal? (8) With regard to sectorless machines, what is "J. W.'s" opinion of them as compared with the ordinary form? (9) Are condensers of small capacity of any advantage for X-ray work with a machine of the above size? (10) Is a journal published in England on X-ray work? (11) Could you give me the address of the secretary of the Röntgen Society? Would it be asking too much of "J. W." to give a short description, with some of the principal dimensions and any novel features, of the large machine exhibited by Mr. Wimshurst at the conversazione of the Royal Society in 1887?—W. G. C.

[97228.]—**Blue Printing.**—Would one of our readers be kind enough to give particulars of chemicals used for blue printing, as engineers use for copying drawings, &c.? —JOHN POLMEAR.

[97229.]—**Voltmeter.**—Will Mr. Bottone, or some other reader, tell me how to make a small voltmeter to read from 1 to 10 volts? Also a small ammeter to read from ·2 to 5amp.?—R. S. V. C.

[97230.]—**The Blue Eye.**—"Helmholtz has irreverently disclosed the fact that a blue eye is simply a turbid medium."—Tyndall, "Lectures on Light," p. 155. Will any reader of "E.M." kindly help me to Helmholtz's words *re* the blue eye?—F. H. E.

[97231.]—**Moving Hearthrug.**—I was recently staying with some friends in London, and, always noticing the hearthrug riding up and over the curb, I remonstrated. I was met with the remark that unless it was fastened to the floor it would resume its position. To test this matter, the last thing before retiring for the night on two occasions I moved the rug 8in. from the curb to find in the morning it had travelled back again. There is about 3ft. space between the floor-joists and foundations. Floor covered with cedar felt, over which is a Saxony velvet square, and upon this the hearthrug, I think technically called or described as "town-made." Will some of "ours" tell me the reason or cause of this (to me) peculiarity?—R. J. NEWCOMB.

[97232.]—**Maxim Guns.**—Can any reader give me a description of the Maxim guns mentioned in this paragraph from *Fielden's Magazine*?—"The Boer army is equipped, in addition to Schneider, Krupp, and other ordnance, with several batteries of the 37-millimètre Maxim automatic gun firing shells, and now used for the first time in civilised warfare. These guns were supplied several years ago with the full knowledge of the Home Authorities. Whereas the ordinary Maxim fires only rifle bullets, the 37-millimètre piece fires a shell weighing about 1½lb. at the rate of 300 shells a minute, with an effective range of 2½ miles. That is to say, it will throw 375lb. of explosive projectile a minute among the enemy at the range mentioned. The gun with its mounting weighs about a quarter of a ton, and can be worked by one man only."—R. V.

THE total output of coal from mines in the United Kingdom last year was 202,042,243 tons, and from open quarries 12,273 tons, making a gross total of 202,054,516 tons, a decrease of 75,415 tons compared with 1897.

THE production of sulphur in Sicily amounted to 3,000,000 tons in 1897, which grew to 3,200,000 tons in 1898. In 1898 the principal buyers were the United States, 142,553 tons; France, 95,000 tons; Continental Italy, 60,919 tons; Germany, about 27,000 tons; and Great Britain, with Malta, only 26,487 tons.

Retouching Desk.—Presumably no house is without a mirror, neither is any amateur photographer without a printing-frame. It does not interfere with the usefulness of the latter for printing if made to serve an additional purpose. By screwing a pair of wooden supports fairly fast to the sides of the frame, it can be made to stand at any desired angle with the back of the frame towards you. (The backboard is laid aside for the time being.) A mirror is laid face up on the table, and near to the window; the printing-frame converted to a retouching-frame is placed over it. The window-blind may be lowered to the required extent, and so protect the operator from conflicting lights. Sometimes a book may be laid behind the mirror to prevent any sliding or shifting. Retouching and blocking-out may be done as carefully as in the most expensive retouching desks.—THE PHOTOGRAPHIC TINKER, in *Photographic News.*

ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries, put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

*** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

The following are the initials, &c., of letters to hand up to Wednesday evening, Dec. 6, and unacknowledged elsewhere:—

SECULARIST.—Manx Visitor.—Anxious.—Westminster.—A. B. McDowall.—Student.—Jack of All Trades.—J. Matthewson.—G. Bousfield.—Richard Hudson.—S. Reynolds.—Le Vilcoq.—Theodore Brown.—F. H. Ewers.

A STUDENT (Oldham).—We can send you the book, post free, for 8s.

J. M.—The articles on Oil-Engines, by Mr. Taylor, commenced in No. 1601, and concluded in No. 1606.

J. K. A.—Probably the apparatus for filtering rain-water, illustrated on p. 187, is what is meant.

D. P. W.—Do not know of any work giving instructions as to the method of working a patent; but as to taking out a patent, please see the advertisements on front page.

A. HARSTON.—Thanks. As you point out, the decimal point has been omitted.

J. D.—In Manchester you can see the works and form your own opinion as to their suitability to your requirements. "The Marine Steam-Engine," by Sennett and Oram, published by Longmans, price 21s., is a standard work.

STEN.—In our opinion there is no other really *good* system. For private memoranda the best way is to use a cipher code. Many volumes back we gave all the space we can or could spare for the discussion of merits of various systems of shorthand. Lewis's (now nearly obsolete) and Gurney's are the only two other systems we have practical acquaintance with. They had each good points, but were inferior to Pitman's.

T. G. ROBB.—Full particulars can be obtained from the Programmes and Prospectuses published by the Institutions or Societies, which are sold by all booksellers. The "Directory" of the Science and Art Department is published by the Queen's Printers, price 6d., and that will answer the other question about the Whitworth Scholarships, and the City and Guilds Institute, for which last, however, apply to Gresham College, Basinghall-street, E.C.; the programme costs 3d. Full particulars can be obtained on application at any of the science classes.

NEMO.—Of what is the stand composed? The bits of "cement" seem to be composed of pitch and cinder-ash or fine mould. That can be moulded into all sorts of shapes very easily, and be touched with greenish paint to give the appearance of moss.

R. M., Leith.—The book referred to does treat the subject fully, and so do several others. It has also been fully described in back volumes (amongst the L.'s) and in many others. Several manuals have been published on electric-bell fitting and wiring for electric light. "The Internal Wiring of Buildings," by H. M. Leaf, published by Archibald Constable and Co., is a good work.

DYNAMO.—Such information can be found in many of the books which are available in the free libraries of your city. The usual plan to "take up" a career in any branch of engineering is to become either an articled pupil or an apprentice.

IN TIME.—We shall probably stop the sale of our 'Best Books" soon after the end of the year, so that you had better order before Christmas to make sure of getting a set.

PUZZLED.—Such problems are not worth their space.

W. P. THORP.—We suppose plenty of other poisons are taken daily in drugs! We should not swallow kerosene ourselves, but the small quantity mentioned by the correspondent would not, we fancy, result in a coroner's inquest. We believe the earliest use of the petroleum oils was medicinal, internally and externally. There is nothing that the average man will not swallow, one time or another, as a drug!

H.—We do not know a book. Batsford, 94, High Holborn, W.C., may.

F. C. LAMBERT.—Look through the "Sixpenny Sale Column." Mr. Allsop's book is as good as any.

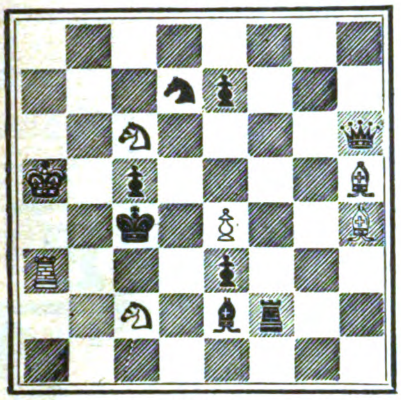
THERE are 20 carbide manufactories in France, most of them obtaining their current by means of water power.

CHESS.

All communications for this column to be addressed to The Chess Editor, at the Office, 332, Strand.

PROBLEM No. 1704.—By C. A. Gilberg.

Black. [8 pieces.



White. [7 pieces.

White to play and mate in two moves.

(*Solutions should reach us not later than Dec.* 18.)

Solution of Problem No. 1702.—By L. Hawkins.

Key-move, Kt-Q5.

NOTICES TO CORRESPONDENTS.

Problem No. 1702.—Correct solution has been received from Frank Gowing, A. Tupman, T. Clark, Richard Inwards. This problem, unfortunately, has a second solution by Kt-R5, as pointed out by J. E. Gore, C. R. Baxter (Dundee), and F. B. (Oldham), S. Woollen.

Rev. Dr. Quilter.—Can you supply the continuation after Q-QB8?

P. Hutton.—We commend your pluck, although again unsuccessful.

Experiments have been carried out in America with wireless telegraphy, in which a telephone receiver was substituted for a coherer, and is said to have responded to the electric waves, even when the diaphragm was of rubber and the coil removed. The law deduced is that the air in proximity to the conductors conveying big-frequency waves acquires a pulsatory motion, which it may transmit to a diaphragm. The rigid chamber behind the diaphragm should be connected to two terminals in contact with media at different potentials, which media may be the air or the earth.

The Marine Department of the Board of Trade have issued the report for the live-saving apparatus for the year ended June 30 last. During the twelve months 223 lives were saved on 37 occasions by means of the apparatus, this being 92 more than the number saved by the same means during the previous year, and 59 less than the average for the previous ten years. The total number of lives saved by the live-saving apparatus since 1870 is 7,241. During the past year three new stations have been established. The total number of live-saving stations now under the control of the Board of Trade is 313—viz., 297 rocket apparatus stations, eight cliff ladder stations, and eight heaving-line stations. There are also 354 stations supplied with belts, or belts and lines, for life-saving purposes.

TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

5s. 6d. for Six Months and 11s. for Twelve Months, post free to any part of the United Kingdom. For the United States, 13s., or 3dol. 25c. gold; to France or Belgium, 13s. or 16f. 50c.; to India, New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-Office Order. Back numbers can also be sent out by the ordinary newspaper post at the rate of 3d. each.

Vols. XXIV., XXX., XXXII., XXXVI., XXXIX., XL., XLII., XLIII., XLIV., XLV., XLVI., XLVIII., L., LI., LII., LIII., LIV., LV., LVI., LVII., LVIII., LIX., LX., LXI., LXII., LXIII., LXIV., LXV., LXVI., LXVII., and LXVIII., bound in cloth, 7s. each. Post free, 7s. 7d.

Indexes to Vol. LI., and to subsequent Vols., except Vols. LIII., LV., LVI., LVII., LIX., LXI., 3d. each, or post free 3½d. Cases for binding 1s. 6d. each.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each post free from the office (except index numbers, which are 3d. each, or post free 3½d.)

NOTICE TO SUBSCRIBERS.

Home Subscribers receiving their copies direct from the Office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a Pink Wrapper, as an intimation that a fresh remittance is necessary if it is desired to continue their subscription.

Foreign Subscribers will have the Pink Wrapper sent One Month before expiration, in order to give them time to forward fresh remittance before subscription expires.

ADVERTISEMENT CHARGES.

The Charge for Advertisements in the Columns headed:—

For Exchange.
For Sale.
Wanted.
Addresses.
Situations.

is Sixpence for the first Sixteen Words, and Sixpence for every succeeding Eight or part of Eight, which must be prepaid. *No* reduction on repeated insertions. Advertisers should state under which heading they wish their announcements to appear.

The address is included as part of the Advertisement and charged for. No displayed Advertisements can appear in above columns. Rates for Displayed Advertisements are as follows:—

For advertisements on inside pages, except page facing leader, for less than a quarter-page; per inch single column—

1	6	13	26	52 insertions
7s. 0d.	6s. 6d.	6s. 0d.	5s. 6d.	5s. 0d. each.

Per Column.—

1	6	13	26	52 insertions
£3 0s.	£2 15s.	£2 10s.	£2 5s.	£2 0s. each.

	1	6	13	26	52 insertions.
	£ s.	£ s.	£ s.	£ s.	£ s.
Per Page	8 8	7 0	6 0	5 5	5 0 each.
Half-page	4 10	3 15	3 10	3 0	2 10 ,,
Quarter-page	2 10	2 5	2 0	1 15	1 10 ,,

Back Page, £10 10s. A few dates open during 1899.

ORDINARY ADVERTISEMENTS.

	£ s.
Thirty Words	2 6
Every Additional Eight Words	0 6

Front Page, Five Shillings for the first 40 words, afterwards 9d. per line. Displayed Advertisements, 10s. 6d. per inch. Paragraph Advertisements, One Shilling per line. No Front Page or Paragraph Advertisement inserted for less than Five Shillings.

All Advertisements must be prepaid, and in cases where the amount sent exceeds One Shilling, the Publisher would be grateful if a P.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.'s.

Advertisements *must* reach the Office by 1 p.m. on Wednesday to insure insertion in the following Friday's number.

For the convenience of advertisers, replies to advertisements (except those in the Exchange and Sale Columns) may be addressed to "———," care of the English Mechanic Office, and will be forwarded by post to the advertiser, for an extra fee of Sixpence per insertion over and above the cost of the advertisement.

All Cheques and Post-Office Orders to be made payable to The Strand Newspaper Company, Limited, and all communications respecting Advertisements should be distinctly addressed to:—

THE PUBLISHER,
THE "ENGLISH MECHANIC,"
332, STRAND, LONDON, W.C.

This is necessary, as there are several papers published at the same address, and unless letters are fully directed, it is impossible to tell for which paper they are intended.

For Exchange.

The charge for Advertisements in this column is 6d. for the first 16 words, and 6d. every succeeding Eight, which must be prepaid.

Special Notice. — *Correspondents are strongly recommended not to send money or goods to strangers. The safest way when dealing with unknown advertisers is to send a Post Office Order made payable —— days after date, when in case of non-arrival of goods, or dissatisfaction, payment can be stopped.*

Printing Press and Type, outfit complete, value 50s. Offers, cash or exchange.—Apply Adams Bros., Daventry.

Wanted, a **Treadle Lathe**, by good maker. Give Pedigree Mastiff Bitch, value £10; or Mastiff Dog (prize winner), value £15.—Beanland, Odiham, Hants.

Calver Reflecting T lescope, 8½in. mirror. Exchange for good, light, back-geared Lathe.—Banks, Corporation-street, Bolton.

6½in. **Equatorial Reflector** (Calver), heavy iron stand, slow motion, fine instrument; exchange refractor, or sell. Seen by appointment.—C., 16, Sunningfields-crescent, Hendon, N.W.

Pair Pneumatic-Tired Wheels, secondhand; small Lathe, 2 cast steel headstock mandrels. Exchange Camera, or Musical Instrument. Letters only.—Cripps, 13, Henrietta-street, Deptford.

Wanted, Berliner's Gramophone, Diaphragm; exchange 25-string Triumph Auto Harp or new Silver Lever Watch, value, 20 each.—James Sharp, High-street, Sanquhar, Dumfriesshire.

"**Jamieson's Celestial Atlas**," 30 plates, figured constellations, descriptive and explanatory, published 25s. Exchange for good Field-Glass, or Cash offer.—Desmond, 50, Woodchester-street, W.

For Sale.

The charge for Advertisements in this column is 6d. for the first 16 words, and 6d. every succeeding Eight, which must be prepaid.

New Illustrated Price List of Screws, Bolts, and Nuts for model work, drawn to actual size, sent on receipt of stamp.—Morris Cohen, 132, Kirkgate, Leeds.

Watch and Clock Tools and Materials. Catalogue, over 1,000 Illustrations, post free, 6d.—Morris Cohen, 132, Kirkgate, Leeds.

Wheel-cutting and Dividing in Brass or Iron to 12in. diameter.—Clegg, Belinda-street, Hunslet, Leeds.

Lathes and Machined Parts, Wheels, Chucks, Fans, Angle-plates. Illustrated list, 2d.—Jarratt, Queen-street, Leicester.

Eyesight.—All whose sight is in any way defective should send to Horne and Thornthwaite, 416, Strand, for—

"**Hints on Spectacles**" (Why the Eyes want Help), by Overstall, F.S.M.C. (with distinction), post free.—Above.

Rubber Outer Covers, 3s. 6d. Prepared Canvas, 90 by 9, 1s. 3d.; rubber solution, best quality, 1lb. tins, 1s. 6d.—Pemberton.

Air Tubes, all sizes, best quality, 2s. 9d. each. Air tubes with Dunlop valves fixed, 3s. 9d.—Pemberton.

Cushion Tires, 3s., 4s., 5s. Solid Tires, 3s. All sizes stocked.—Pemberton.

Detachable Outer Covers (Licensed), 12s. 6d. each; all cycle accessories and cycle rubber goods stocked.—Pemberton and Co., 1, Cardwell-place, Blackburn.

Nuts and Bolts for Model Work. Illustrated List, 2,800 varieties, 3d.—Butler Bros., Haggerston, London.

Screws, Screw-plates, Taps, round and hexagon special steel brass and iron rods. See list.—Butler.

Rubber Outer Covers, average 16oz., Para rubber 5s. each.—Franklands.

Rubber Outer Covers, 3s. 6d. each, 36s. per dozen.—Franklands.

Cushion Tires, 3s., 4s., 5s. Solid Tires, 2s. 6d., 3s. All sizes stocked.—Franklands.

Air Tubes, best quality rubber, 2s. 9d. each. Fitted with Dunlop valve, 3s. 9d.—Franklands.

Air Tube, Para rubber. Marvellous value. Large stock to clear. Perfectly air-tight., 2s. each.; 21s. per dozen.—Franklands.

Cycle Capes, 3s. 6d., 4s. 6d., 5s. 6d. Also a few cycle Capes, guaranteed waterproof, 2s. 6d. each.—Franklands.

Detachable Outer Covers, licensed, 12s. 6d. each.—Franklands.

Saddles.—A clearing line in ladies' and gents' saddles, 2s. 6d. each, 24s. per dozen.—Franklands.

Inflators, 18in., 1s. 6d. each, 15s. dozen.—Franklands.

Bells.—Special line, double gong, usual price, 12s. dozen, will clear 5s. per dozen.—Franklands.

Prepared Canvas, 90 by 9, 1s. 3d. each, 12s. per dozen.—Franklands.

Pedal Rubbers, 6d. per set of four, 4s. 6d. per dozen sets; no rubbish.—Franklands.

Spanners, nickel, usual price, 13s. per dozen. Will clear a few dozen at 7s. 6d. per dozen.—Franklands.

Cycle Accessories and Cycle Rubber Goods. We hold the largest stock in the North.—Franklands, Astley Gate Blackburn.

Brass and Gunmetal Castings of finest quality. Prices on application.—Daniel Young, Witney, Oxfordshire.

Mail Cart Wheels and Perambulator Furniture.—Walker Bros., Primo Wheel Works, Sheepscar, Leeds.

"**Spesco" Belting Syrup** prevents slipping, and keeps belts in good condition; 1lb. sample tin, post free, one shilling.—Spesco Ltd., Suffolk-place, Bermondsey, London.

Gas-Engine Oil, 1s. 6d. gallon. Cheaper grade, 1s. Cotton Waste, Tallow, Packing, &c. Correspondence invited.—Under.

Polishes, Varnishes, Paints.—Large or small quantities, by rail or post. Benzoline, Gasoline, Mechanical Rubber Goods.

Why Burn Dangerous Oils? We have Safety Kerosene in barrels or drums. Refined quality only.—Under.

Lamps and Stoves Repaired. Wicks and Glasses of every kind. Low prices.—Jones Company, Bethnal Green.

"**Electricity**" is a bright, chatty, and practical journal, which everybody interested in the science should read. Fridays 1d. Of all bookstalls and newsagents.

"**B" Oil-Engine Castings and Forgings.** Easy to make; no complicated parts; very reliable.—Barkers, Leyton.

"**B" Oil and Gas-Engines** are fitted with silent gears, sensitive governors, adjustable bearings.—Barkers, Leyton.

Original Testimonials can be seen at any time, together with English and Colonial Press opinions.—Barker.

"**B" Gas and Oil-Engines.** Supplied the word over. Particulars stamp.—A. and S. Barker, Engineers, Leyton, E.

Launch Oil Engines a Speciality. New designs. High speed. Very reliable.—A. and S. Barker, Engineers, Leyton, E.

Money Saved is Money Earned.—The cheapest house for electric bells, telephones, light material, &c.—Write for catalogues, post free 3d., to C. W. Treacher and Co., 165, Queen Victoria-street, London.

"**Acetylene: its Characteristics, Generation, and Use**," with Descriptive Catalogue of "Incanto" Apparatus; just published, 2d. post free.—Thorn and Hoddle 1 Tothill-street, Westminster, S.W.

Gas and Oil Engines.
Steam Engines.
Dynamos.
New Designs. New Patterns.
Latest Improvements.
Send at once for Latest Catalogue.
H. Warsop, Launder-street Works, Nottingham.

Simplex Typewriter, 14s. 6d., delivered. Thousands in use. Illustrated particulars free.—Atkinson and Co., Harehills-avenue, Leeds.

Model Boiler Fittings and Material, seamless copper tubes, 5-32in., 3-16in., ¼in. up to 8in. diam.—Below.

Steam Gauges from 1in. dial, 60lb., 6s. Warranted ¼in. Wheel Valves, 3s. 11d.; Water Gauges, &c.—Below.

Injectors, Cylinder Lubricators, Lever Safety Valves, Copper Rivets and Sheet Brass and Steel Rods, &c.—Below.

Illustrated Catalogue of above high-class gunmetal fittings, 2 stamps.—Bert Garside, Golborne-street, Warrington.

Brass Casting Made Easy by using Wells' specially prepared Moulding Loam. Brass casting a pleasure.—Below.

Sold in 5lb. canisters, 2s. 3d.; 10lb., 3s. 9d.; 20lb. 6s., carriage paid, with instructions.—Below.

Plumbago Crucibles, with instructions for melting brass, sixpence each post free.—Geo. Wells, Needham Marke Suffolk.

Phonographs, new Gem, take standard records, and are fully licensed, £2 2s.—Below.

Phonograph Records, Bands, Songs, Instrumental Speeches, 2s. 6d. each, post free 2s. 9d.—Below.

Phonograph Accessories, &c.—T. G. Woods and Sons, 51, Spencer-street, Clerkenwell, E.C.

A Perfect Portable Home Turkish Bath, folds into 3in. space, weighs 7lb.—Gem Supplies Co.

The Folding Quaker Bath Cabinet. Cleanses and invigorates, cures diseases without nauseous drugs.—Gem Supplies Co.

A Turkish Bath for a Penny. "E.M" pamphlet free.—Gem Supplies Co., 6, Bishop's-court, Chancery-lane, London.

"Perfect" Pocket Oiler, emits one drop at a time, never leaks, 1s. each.—Gem Supplies Co.

"Perfect" Pocket Oiler.—Best oiler for bicycles, typewriters, or sewing-machines, 1s. each—Gem Supplies Co.

"Perfect" Pocket Oiler, 1s. each. Trade terms on application.—Gem Supplies Co, 6, Bishop's-court, Chancery-lane, London.

Watchmakers, Amateurs, Collectors.—Good watch movements, verge, cylinder, lever, from 1s. 6d.—Below.

Antique Watches, movements, specimens of work for the last 200 years.—Willis.

Boxes of Parts, for repairs, 1s. 6d.—Willis, 19, River-street, London, E.C.

Magnificent Model **Vertical Engine,** tubular boiler, glass gauge, whistle, double-action slide-valve cylinder, bronzed stand, exhibition model, silver-plated, high speed, and guaranteed perfect. Worth 42s.; accept 12s. 6d. free. Photograph 1d.—Manager, Hassall's Chemical Works, Stratford, E.

Motor Cycle Castings, rough or finished, from "E. M.," list 1d.—Homer, 93, Hurst-street, Birmingham.

100 Billheads, Memos., or Cards, post free 1s. 3d.—Young, 57, Leyton Park-road, Leyton.

Watches, Clocks, Jewelry, Musical Boxes, Novelties. Dealers supplied at rockbottom trade prices for cash. Cheapest house in England. Lists on application. Gentleman's crystal face keyless nickel silver, 2s. 9d.; not less than three will be sent.—Woolredge and Co., 90, 91, Queen-street, London, E.C. Agents wanted. Mention paper.

Reliable, efficient **Dynamos, Motors.** New catalogue, stamp.—Webster Michelson Co., Electrical Engineers, Eve-hill Works, Dudley.

Engineers', Cycle-makers', Gasfitters' **Stocks** and Dies, also Taps, all sizes, price list gratis.—Metz, Edgbaston-street, Birmingham.

"The Model Engineer" for November contains:—"My Model Electric Tram-Car" (Illustrated); "Useful Additions to a Screw-cutting Lathe" (Illustrated); "The A. B. C. of Dynamo Design" (Illustrated); "Britain's Latest Battleship"; "Brazing"; "Model Railways" (Illustrated); "The Wehenelt Electrolytic Interruptor for X-ray Work"; "Melting Metals in the Amateur's Workshop" (Illustrated); "Model Yachting Notes"; "Steam Raising in Model Locomotives" (Illustrated); and many other interesting articles. Post free 3d.—Address below.

"The Model Engineer" for December contains:—"Making Cardboard Model Locomotives" (Illustrated); "½H.P. Avery-Lahmeyer Dynamo" (Illustrated); "Liquid Fuel for Model Boilers" (Illustrated); "Model Railways" (Illustrated); "Ringing Two Electric Bells in Series" (Illustrated); "How a Battery Works"; "The Society of Model Engineers' Conversazione"; "Model Yacht Measurement" (Illustrated); "Boilers for Model Torpedo Boats" (Illustrated); "A Cheap Speedometer" (Illustrated); "How to Demagnetise a Watch"; &c., &c. Post free 3d.—Address Publisher, 6, Farringdon-avenue, London, E.C.

Calver's Complete Equatorial, best ever designed, revolving eye-end, set any latitude by screw and vernier at once. Second-hand Telescopes, perfect order. "Hints on Reflectors," 13 stamps.—G. Calver, F.R.A.S., Chelmsford.

Cycle Motor Castings to drawings in Mechanic, most complete. — Everett and Co., 32, Charterhouse - square, London, E.C.

Electric Lighting Plant.—4 nominal horse-power Stockport Engine, 150v. 30a. dynamo, and 50 E.P.S. storage cells, £95. Engine only £40.—Palmer, 6, Upper Tulse Hill, S.W.

30c.p. **Dynamo** (Butler's), charging and lighting amps, holders, wires, new, £4 15s.—4, Dixon-terrace, Darlington.

"Screw-cutting," both simple and compound, explained, with list of wheels, post free, seven stamps.

"Cycle Brazing," four stamps. If you require a good book to learn from, send for this.

"Guide to Soldering," three stamps, which shows how to solder gold, silver, copper, brass, tin, &c.

The Three Books post free for One Shilling Postal Order.—Geo. Harrison, 6, Manning-street, Nottingham, E.

Complete Catalogues.—Electrical supplies, Steam Models, Magic Lanterns, Fretwork materials, and Air-Rifles. Free three stamps.—Greaves and Co., 230, East India-road, Poplar, E.

Films for Tracing Lantern Slides, 4½d. per doz., 1s. three doz.—Photo, 11, Bothwell-street, Glasgow.

Genuine B.S.A. Cycles, from £8 10s. Up-to-date Machines, £4 8s. 6d. Frames, 37s. 6d. Wheels, 12s. pair. New Outer covers, all sizes, 9s. each. Inner tubes, 2s. 6d. Send for lists and testimonials. — Kirkdale Cycle Works, 41, Kirkdale - road, Liverpool.

Pair 5in. back-geared **Lathe Heads,** complete, well made, quite new, 50s. Also pair 5in. single-geared, 30s.; bargains. —Walmsley, 17, Calton-street, Keighley.

Gas, Oil, and Steam Engines, Lathes, Dynamos, &c., all soft metal. List three stamps.—Reynolds Bros., Barnsley.

36 volumes **"English Mechanic,"** 1870–1888, strongly and neatly cloth bound, two vols. in one, excellent condition, £3 12s. the lot. Exceptional opportunity.—Percy Lund, Godwin-street, Bradford.

Motor-Bicycle, double cylinder, with spare wheel, magneto ignition. Has run well, but wants overhauling. Very little used. £10. A bargain. Write for evening appointment to view in North London.—H. C. C., 204, Amhurst-road, Hackney, N.E.

Large Nicol Prism, 1in. diameter, for the study of both ordinary and extraordinary polarisation phenomena, specially made by Hilger, £10 10s.—As below.

Pritchard's Wedge, by Grubb, with extra revolving glasses; cost £9 9s., price £6 6s.—As below.

10in. Reflecting Telescope, with eyepieces &c, by Calver, £60.—C. Baker, 244, High Holborn, London.

Cassell's "Science for All," complete, in 60 seven-penny parts, clean, 12s.—Morrell, Springcliffe, Manningham, Yorks.

50,000 Choicest Microscopical Objects, New and Second-hand Microscopes, Cabinets, Mounting Materials.—Suter, 10, Highweek-road, Tottenham.

Ornamental Design, Hay, published 42s., take 10s. Two Mummied Cats' Heads, 7s. 6d.—Walker, Church-lane, Liverpool.

Shells.—Large quantity British and Foreign, named, 40s. Iron Pump, 6s. Exchange.—Walker, Church-lane, Liverpool.

Whiteley Exerciser, new, 9s. Quaint old Microscope and objectives, 20s. Exchange tools.—Walker, Church-lane, Liverpool.

Bench Lathe, 3½in. centre, driving wheel, £1. Gas-Engine, 12s. 6d.—Grumble, St. Nicholas street, Leicester.

Vertical, double-cylinder, **Scale Model Marine Engine,** 1in. by 1in. cylinder, reversing gear, £2.—H. Bolsover, Yarm.

Lathes, Drilling, Planing, Milling, Shaping Machines. Britannia Co., Bonâ-fide Makers to the British Government.

Iron Castings, various, good working quality. Prompt execution of orders.—Britannia Foundry, Colchester.

Britannia Co. Heavy Department make Tools, &c., up to 20 tons. They also continue the Light Tool Department.—Write Britannia Works, Colchester.

Britannia Co., having erected large foundry, fitted with electric light and crane, are open to supply light or heavy castings.—Britannia Works, Colchester.

Fancy Ornamental Lathes, by Holtzappfel, Evans, and various first-class m·kers, and various appliances on sale. —London Machinery Agency, 100, Houndsditch.

Special Tools, as designed for eminent firms, for any special work; interchangable.—Britannia, Colchester.

"Gem" Gas-Engines. ⅛B.H.P., Otto Cycle, well made, best and cheapest offered.—Crewe, below.

"Gem" Gas-Engine Castings Supplied. Most easily fitted. Complete sets partly machined.—Crewe, below.

Gas-Engine, second-hand, Crossley, 2-man power, cheap.—Crewe, 78, Queen Victoria-street, London, E.C.

Horizontal **Gas-Engine,** 3½in. bore, 6in. stroke, tube ignition, two flywheels, good as new, £7 10s., on rail.—Brown, 9, Henry-street, Lytham, Lancs.

Second-hand.—Linesman's **Galvanometer and** Telegraph Instrument. Price and particulars — Hargrave, 4, Fowett-terrace, Morley, Leeds.

Books. — Spon's "Workshop Receipts," Spon's "Mechanic's Own Book," "Machinery and Millwork," "Turning Lathes," Work Handbooks. Quantity other books; all cheap.—Angell, London-road, Boxmoor.

Siemens **Dynamo,** shunt wound, 40 to 50 volts, 16 to 20 ampères, about 1600 revolutions. Complete order £10.—Tuer, 13, Park-road, Bellevue, Southampton.

Model Boiler, 13in. tubular, nearly new, tested 50lb., brass mountings, 17s.—51, Winchester-road, Romsey.

Complete Sets **Water Motor Castings,** ½-horse. 20s.; ½, 30s.; ¾, 40s.; 1-horse, 50s. Satisfaction guaranteed.—P. Pitman, Halifax.

Water Motor Castings.—The Superintending Engineer, L. & N.W.Rly., says:—"I fitted up the water motor from your excellent sets of castings and fittings, and it runs beautifully, and is now driving my 3in. centre screwcutting lathe."—P. Pitman, Halifax.

Water Motors, Turbines, Water Pressure Engines, Dynamos, Castings. Illustrated lists, 3d.—Pitman, 64, Stanley-road, Halifax.

Marvellous Value!—All Shopkeepers should send for one of our wholesale cases well assorted Fancy goods, Toys, Household Requisites, Special Lines, £1, £3, £5, £10, carriage paid.—Barnes, 41, Kirkdale-road, Liverpool.

Lathe, 4in. centre, chuck, T-rests, &c. Vice (leg), 5½in. jaws; 5ft. 6in. Bench; Anvil, about 2cwt. Surface-plate, 1ft. 7in. 14lb. Hammer, and Mandrel. Take £5 5s. for the lot. A bargain.—F. P., 52, Dieppe-street, West Kensington.

Slide-Rests, compound, all sizes, best make, latest improvements, low prices. Also Vertical Slides.—Neilson, below.

Oval, Eccentric, Geometric **Chucks,** drilling, planing, shaping, and milling attachments.—Neilson, 45, Hollydale-road, London, S.E.

½B.H.P. Vertical Launch **Oil-Engine** (Barker), nearly new, guaranteed order, £9 on rail.—Gunter, Waterside Farm, Thatcham.

Two **Telephone Stations,** complete, speak five miles, 15s. both.—W. Parker, Victoria-street, Littleborough, near Manchester.

Lathe, 4in., 4ft. planed bed; also Iron Stand. Exchange.—Newton, 54, Wilson-street, Teams, Gateshead.

Bookbinding, without special tools. Materials and instructions for binding English Mechanic, 9d.—Bean, Montague-street, Hartlepool.

First Step in Bookbinding. — Bind your English Mechanics. Instructions and prepared material, 9d.—Alfred Bean, Hartlepool.

Material and Instructions for binding in best cloth any book, 9d. State size.—Alfred Bean, Hartlepool.

Juvenile **Safety Bicycle,** diamond frame, 12s. 6d.—Hazell, 124, Essex-road, Islington.

Flat Piano, by Clementina, 30s.—Hazell, 124, Essex-road, Islington.

Motor 2½H.P. (cycle), cylinder bored, crank case fitted, plunger turned, combustion chamber finished, £6 10s.—Below.

Motor, 3H.P. Horizontal, perfect, new condition, latest type, £18.—Harcourt Engineering Co., Old Town, Clapham.

Polished Plate Specula Discs, rough or ground edged, 12½in., 12s. 6d., 20s.; 8½in., 4s., 7s. 6d.—Holmes, Essex-road.

Chamber Organ, or suit mission, handsome case, seven stops, fine tone, £19.—253, Southwark Park-road.

Motor Cars, Tricycles.—Casting, finished parts, accessories, and complete sets supplied for the De Dion, Daimler, Hwila systems. Write for list, 1d. stamp.—J. Phillipps, 64, Victoria-road, Holloway, London, N.

Christmas Presents. — Large Illustrated List Electrical and Mechanical Novelties, two stamps.—T. W. Suter, South Tottenham.

A STITCH IN TIME SAVES NINE.

But you will save more than that by smoking the *Weekly Times and Echo* Cigar which only costs *twopence*, and is equal, if not superior, to any other cigar which costs three or four times the price. We are selling (and tobacconists all over the country can supply you if they like) this cigar as a gigantic advertisement, because we know that wherever the cigar goes the marvellous value we are giving smokers will be a matter of universal comment and astonishment. See that every cigar has the *Weekly Times and Echo* band round it, and is sold from a box similarly labelled and branded: otherwise you will not be sure of getting for twopence a cigar which would otherwise cost from three to four times the price.

MASON'S

NATURE'S OWN BEVERAGES
NON-INTOXICATING.

MASON'S WINE ESSENCES become famous wherever they go. They are pronounced the Ideal by all who try them. Imitators may imitate, substitutors may substitute, but for delicious flavour, absolute purity, Mason's Wine Essences are unapproachable.

6D. BOTTLE MAKES 60 GLASSES

of the most palatable fruit wine, suitable for all ages. Sample Bottle post free 9 stamps.

WINE

MASON'S COFFEE ESSENCE is recognised everywhere as the standard of purity. Have you tried it?

SPECIAL OFFER.

Until December 31st, every purchaser of a Sample Bottle of Wine Essence will be presented with a Sample Bottle of our COFFEE ESSENCE and a MONEY BOX.

NEWBALL & MASON, Nottingham, Makers of Mason's Extract of Herbs; *Agents Wanted.*

ESSENCES

For Sale, the first 4-cylinder **Oil-Engine** ever built, 3in. cylinders, built for experimental purposes, ½H.P. No vibration in this engine.—Apply Harry Lind, Maltese-road, Chelmsford.

Large Illustrated Electrical List, penny stamp. —Dept. A, The Brotherhood Church, Leeds.

Second-hand Stage Arcs, 35s. each; 2 resistances, 17s. 6d. each. Electrical Supplies cheap.—Gateshead Electric Co., Gateshead-on-Tyne.

Mee's **"Heavens at a Glance, 1900."**—Handy Card Calendar. 7d. post.—4, Park-terrace, Penhill, Cardiff.

"Designing and Drawing," No. 1 of The Useful Arts and Handicrafts Series of Books is ready.

"Wood Carving for Beginners," No. 2 of The Useful Arts and Handicrafts Series, ready to-day.

"Picture-Frames by Novel Methods," No. 3 of The Useful Arts and Handicrafts Series, ready December 7th.

"Dyes, Stains, Inks, Lacquers, Varnishes, &c.", No. 4 of Useful Arts and Handicrafts Series, ready December 14th.

"Decorated Woodwork," by carving, colouring, and wire inlaying. No. 5 of The Useful Arts and Handicrafts Series, ready December 21st.

"Gouge Work and Indented Woodwork," No. 6 of The Useful Arts and Handicrafts Series, ready December 28th. Price 6d. each net, post free 7d. Of all booksellers,

Newsagents, &c., and **N. Dawbarn and Ward** Ltd., 6, Farringdon-avenue, E.C. Full prospectus post free.

Arthur Mee's "Observational Astronomy," Practical. Profusely illustrated. Unrivalled at the price. 2s. 9d. post. —*Western Mail*, Cardiff.

Armstrongs' Pocket Accumulators, Hand Lamps, Photographic, Cycle, and Reading Lamps, Scarfpin Sets, Dynamos, Motors.—Armstrongs.

Armstrongs for thorough good Accumulators. Send to us when requiring something good at ridiculously low prices.

Armstrongs are Makers of over 600 sizes in Pocket and Portable Accumulators. Fully illustrated catalogue, 4d.

Armstrongs' "Searchlight" Cycle and Reading Lamps used in preference to all others. See illustrations in catalogue.

Armstrongs for practically mounted Scarfpins, Ammeters, Voltmeters, Galvanometers, Motors, Charging Dynamos, and Accumulator Charging Batteries.

Armstrongs advise you to get their Catalogues, testimonials, &c., when requiring above goods.—Armstrong and Co., Twickenham, London.

Fretwork, Carving. Lists free.—Henry Zilles and Co., Importers, 19 and 21, Wilson-street, Finsbury, London.

New Engine Castings.—½-horse, 5s. 6d.; ¼-horse, 11s. per set. Catalogue 2d.—Tomlin, Ironfounder, Oldham.

Universal Tool Holder, for boring and turning. Simplest ever invented. Rigid under heaviest cuts. List free.

⅜in., 2s. 6d.; ½in., 3s.; ⅝in., 3s. 9d.; ¾in., 4s. 9d.; 1in., 6s.; 1¼in., 7s. 6d., with six-cutter free.—Below.

Workmanship and Finish Guaranteed. No projecting part.—Flower, Engineer, 65, College-street, Putney, S.W.

Gannon's Printing Works, Chelmsford.—Engineers requiring printing should send here. Estimates'stamp. Best work. Lowest prices.

Launch and other Steam Engines, Boilers, Lathes, Propellers, and all kinds of machinery.—S. Smith.

Fly-Press, on stand, for stamping, &c., 50s.—S. Smith, 3, West-street, Soho, W.C.

"Small Accumulators," "The Slidevalve," "Electric Bells." Three splendid handbooks for amateurs or students, 7d. each.—Below.

Bichromate Batteries, with lifting zincs, 1s. 4d. and 1s. 10d. each, free.—Below.

Electric Lamps, 2 volt, 6d. Holders, 4d. Reflectors, 3d. Warranted.—E. Whiting, 109, Fore-street, E.C.

The English Mechanic
AND WORLD OF SCIENCE AND ART.

FRIDAY, DECEMBER 15, 1899.

INLAYING.—X.

ANOTHER plan is to prepare the bed in cement first, and when dry flatten down with a piece of pumice-stone, and centre or deepest tints, and blending off by gradually using the lighter until the bright lights are gained.

To help as much as possible, it will be found that if a water-coloured drawing is made, and you work upon that, the selecting of the different tints and shades will be more quickly accomplished.

As it is impossible to get that softness that the pencil or paint-brush will give, it behoves one then to use as small squares as it is possible to prepare, and the cement used to

Another plan with cement mosaic is to prepare a stout piece of board, size it, and give it two coats of varnish. The first must dry hard, the second coat can be wet for our purposes, but not of too great a body—in plain words, thinly laid on. Having your specimen ready and hard dry, level the surplus projections of cement that may remain after assembling, and then rough the surface with coarse grit or sand. The assembled or mosaic surface is intended to be attached to the wet varnish. When all is perfectly dry,

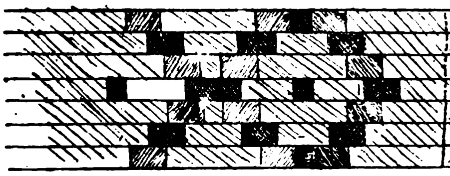


Fig 157

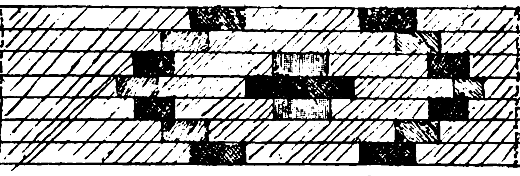

Fig 158

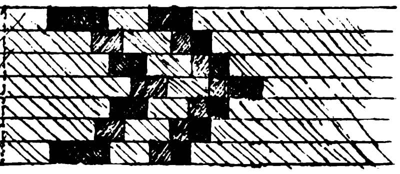

Fig 159

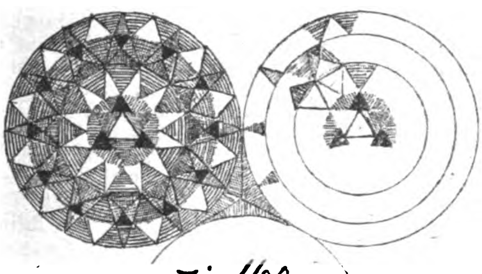

Fig 160

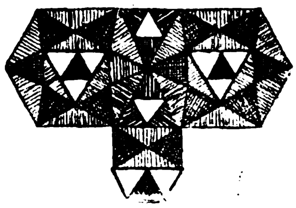

Fig 161

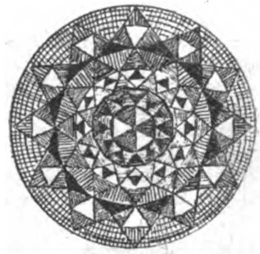

Fig 162

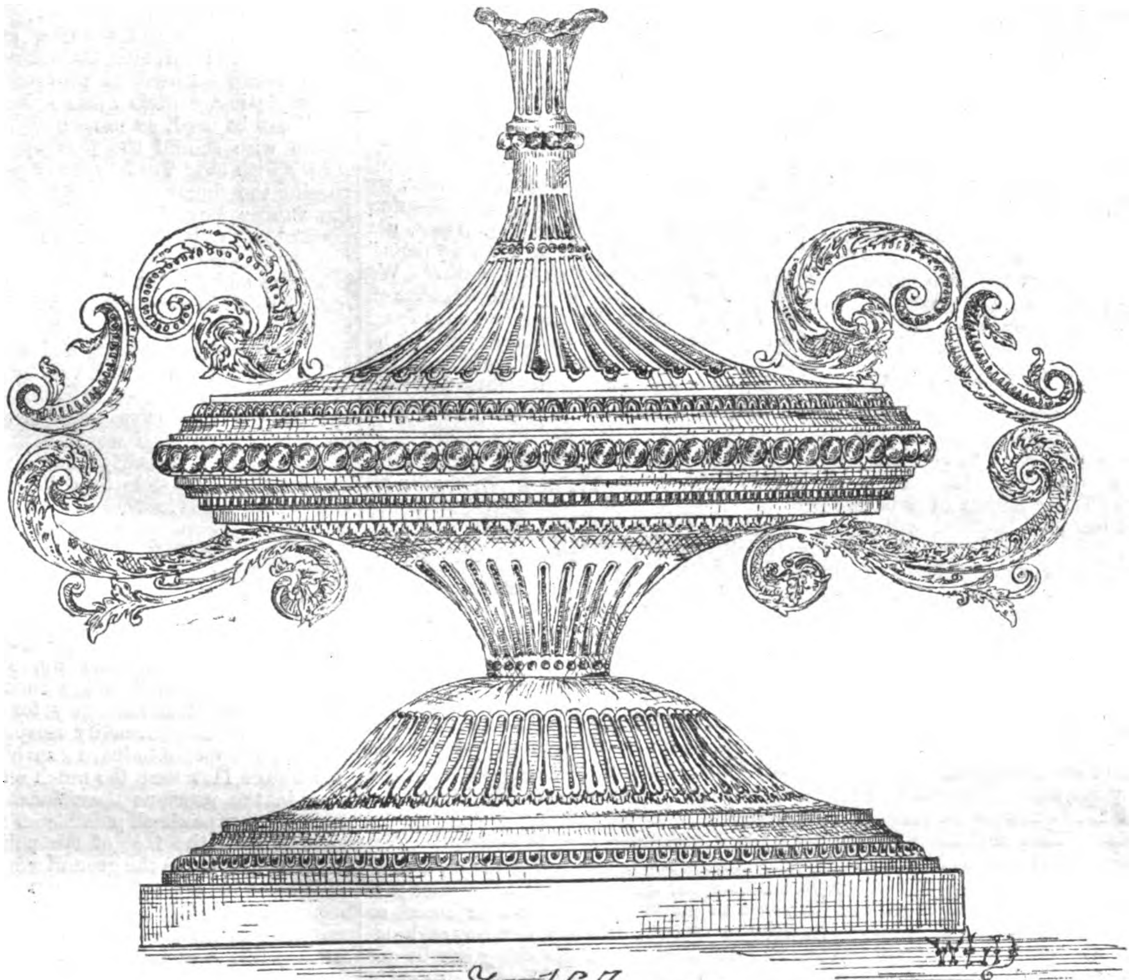

Fig 163

mark the outline on it and proceed to build together the small square on the outlines first, then fill in the body. The shading can easily be got by working up the different tints, using a dark tint for the attach them together must be fairly thin or fluid. Under any circumstances the drying must be gradual. If hastily dried there will be but little chance of shifting over if found necessary in assembling or putting together. the bed above alluded to can be cut down with coarse sand, but no more than is necessary to get a level surface, although that surface may contain some hundreds of pieces; it will now show any defects of

assembling if due care has not been bestowed in the preliminary stage. The after-process is simply to get the coarse marks out with finer grit, finally polishing with snake stone.

The wood process is very similar in many respects, only in lieu of fluid cement we prepare our drawing-paper by coating it with two fairly thin coats of glue or gelatine. The coating must be done after the drawing is traced in, and it is for that purpose we use clear glue in preference to the ordinary Scotch. Do not wet in more than, say, about 1in., and while assembling the wood square, the outer face can have a little rubbed in to help it in remaining intact. If by chance the wood mosaic should curl up, it will be best to desist, and gently flatten out. If not done, there will be trouble in assembling the adjoining portions.

The cutting of the strips can either be done with a fine circular saw, or the gauge of the cabinet-maker. It will be necessary to have all the strips well taut (close together), and the tooth of the gauge should be very sharp, in fact the keen edge should be got up on the oilstone. In cutting, the tooth of the gauge should incline over, like a paring-knife, for the simple reason that if the tooth of cutter is too upright, it is just possible your cutter will send the small pieces all over the place. It will be found necessary to have a weight of some sort to keep all the strips down, and the edge of the same, if square, should be brought up as close to the cutting end as possible, yet not foul the gauge holding the cutter. When all is together a piece of paper should be glued over all the surface and allowed to dry.

Up to now the work has been to unite together a number of small pieces to represent the whole, whether it be cement or wood. With the former there need be but little fear of its curling up; with wood it is vastly different, and it is for that reason we deem it advisable to comment further. As above stated, it is possibly curled or somewhat buckled; if so, we must proceed to warm a piece of wood (caul), and at first simply lay it on and let its own weight regain flatness, and that must be repeated perhaps three or four times; but in no wise must force be used until such times as the face is flat or nearly so; then pressure can be brought to bear upon it. Should the caul be overheated, it should be just sufficiently let cool to keep the glue as nearly approaching a fluid state as possible.

The veneering has been explained in the part allotted to "Buhl-work," and the same amount of care is necessary to prepare the face when the veneering is hard and thoroughly dry. The addition of a border or frieze around the mosaic panel will conclude this part.

Figs. 157 to 162 give specimens of Indian ivory and metal-work. Fig. 163 is what can be done in wood, metal, or mosaic work and engraved. In either material the work can well be enlarged three to four times, and, if well done, should look handsome.

French Polishing.

The ground of the wood will be treated first. We speak of wood generally as being "dead"; it is quite the contrary—it is the *life* in the wood that answers so readily to climatic changes. That shrinking in hot weather and contracting in cold is continually going on. What does that suggest? Simply this: We employ a grain-filler that may or may not act in unison with the wood we desire to polish, and we get a surface like marble or like sponge! What, then, is wanted is a filler that must lend itself to the natural action of the grain of the wood it fills. Plaster of Paris, brickdust, ground resin and shellac have each and all been found wanting, although much is now done with the first-mentioned. There is not a particle of elasticity in either three.

Having had a set of dining-table tops to polish, we could not help remarking upon the excellence of the colour, the evenness of the texture, or face of the tops, and the apparently marble-like appearance of the tops themselves. We polished them, and were greatly surprised with their appearance, and the small quantity of polish required to gain a truly beautiful surface. Inquiry elicited the fact that the tops had been in the family a number of years, and were touched up with linseed oil and turpentine, drying up all surplus, or superfluous grease, with waxed rags.

The above facts induced us to experiment. We found that resin, with and without shellac, tended to a rounded form, and so did brickdust. That the finer they were ground the more globular they became, but with pumice-stone we certainly found the conditions different. Instead of tending to a globular form, its particles presented always the porous nature of sponge, even when ground to a very fine state. We next sought the liquid best to use in conjunction. Oil itself was out of the question, and only with plaster of Paris was it a partial success, whereupon we added the everyday turpentine, and, so far, satisfactorily; but how to eliminate the partial greasiness of the turpentine, and that quickly? We found it next to impossible. Knowing that boiled oil had a tendency to harden quicker than ordinary oil, we made up a filler of pumice-stone and boiled oil made fairly hot, and just a trace of common wax to aid, as we thought, the tendency to dry or set hard. We were successful, and where time has permitted we have ever resorted to its use. We have found that the atmosphere acts but slightly either to soften or harden it after the polishing is done.

For the guidance of the reader, we may say the drying-up process after the above filler has been rubbed in, and while in a warm state, is greatly helped with finely-sifted plaster of Paris.

Ere we proceed to the polishing proper, we think it advisable to discuss the "cleaning up." There are grades of *glass-paper*, not sand-paper as is often advised, from "flour" to what is known as "gravel-walk." We have only to do with the Middle 2, Fine 2, and No. 1½. After the work has been freed of all glue and paper, the work should be *toothed down* with a tool or plane, with the cutting-tool set nearly upright, the iron itself having a number of fine cuts upon its face exactly like a fine file "single cut." If we grind the reverse side or face upon an angle similar to any ordinary plane-iron, we shall have a number of fine teeth or points according to the face cut of the iron. It should project just enough to *lightly* cut or mark the face of our work. If it projects too far, it is liable to drag out some of the finer cutting, or the little squares of the mosaic inlay. Having levelled the work no more than is necessary, it must be scraped with a steel scraper, then papered with middle or fine 2, finishing with No. 1½. In papering up work, a flat piece of cork or wood (pine) should be used. Some cabinet-makers glue a thin layer of about ¼in. of cork on to the pine, and when dry flatten the cork on a coarse sheet of glass-paper, which should lie on a flat bed of either iron or glass.

The work now being ready for polishing, the filling in, as above, is now done; if allowed to stand for twenty-four hours, so much the better. After a few hours, however, the first stage of polishing can be got on with. With some wadding a rubber is made that can be held between the index finger and thumb. Some use two, others three fingers in conjunction with the thumb. Over the rubber is stretched some clean, old white calico, and twisted round the top of the rubber, and held with it. The rubber should approach the form of a cat's foot. It can even be pointed a trifle, with the index finger lying exactly in the centre of the projecting portion of the rubber.

It may be advisable to oil-in the surface. With this exception light woods should not be oiled, as it is desired, of course, to retain their whiteness as perfect as possible. All white, or light-coloured grounds should have either transparent or white polish used in conjunction.

Having the work ready, pour a little polish on the wadding, covering it with the rag as explained. No perceptible difference will be found after three or four rubbers of polish have been spread over the surface, and it is as well, as soon as a slight shining appearance has been gained, to set the work aside, for two reasons:—Firstly, we have used oil in dark work, and it would be best to let the work stand ere we use any more oil; secondly, we are compelled to use a little oil to assist the rubber. For this reason the shellac solution cannot set hard enough in working to prevent the future coats adhering in mounds or hills, which would tend to spoil the work, irrespective of trouble in gaining an even body, which must exist to receive the *finishing* that all polished or bodied work has to undergo. After the first coating is hard the surface is again levelled down slightly, not only to level or cut down the excess polish, but likewise to lower the projecting edges of the cavities that tend to swell and rise. It may be here stated that the first coatings of polish answer a twofold purpose, they not only help to fill up what grain may be open after the filling in, and also act in the same manner as size with the painter, or rather painted work.

Having levelled the surface down with the worn out No. 1½ glass paper, the same filling of rubber and working as before is gone through; but, after the second rubber, a little oil can be used to prevent the polish accumulating, a little more liberal addition of oil can be used, as more polish is applied. In no wise should the face appearance be glossy with oil. That is easily perceived by passing the finger over the face lightly: if the rubber mark is still existent, and is not marked with the finger, then more oil (a drop or two here and there sprinkled on) can safely be added; but if there is a decidedly greasy smear across the polish, then the oil supply must be stopped. As the body of polish begins to thicken, and if the smear left by the polish in the rubber is not too dense, then the process of bodying or building up the successive coats of polish will eventually give good work, both as regards soundness and equality; but if the polish rubber seems to slide over the work, then less oil is used in the succeeding rubbers of polish necessary to obtain a body for finishing.

The defects of the above process will be palpable after the work has stood aside for at lease twelve hours, and are as follows:—If the circular rings of polish are fixed—that is to say, cannot be rubbed up, and the oil smear is very thin, then the work will be as near right as it is necessary for finishing; but if the oil smear readily escapes from the polish, yet appears to leave a surplus behind, it is a sure fact that too much oil had been used in the previous operations. Now endeavour to wipe all oil possible off the polish, so as to leave the face of the polish bright. If the polish leaves the ground when pressure or friction is used, then the use of oil had been resorted to at too early a stage, and may lead to serious results. Again, if too much polish is worked on the face, or even if the rubber is over-charged, then the surface polish that is being laid on has not hardened as it should do. The remedy then is to level all down to the groundwork, and begin again, noting well that if the polish rubber seems to bite or grip the underlying polish then all is well, even though we use oil to lighten our labour.

The work should now stand aside to

harden, because the *spiriting-off*, as it is termed, will give better results than if finished off on semi-soft polish.

It greatly enhances the quality of the finished polishing if two or more bodies of polish are applied, especially if the surface is just levelled a trifle. The safest method of levelling is done as follows: Have ready a strip of felt about 1½in. wide, and long enough to make a round wheel-like form. Insure having one face flat—the other does not matter. When wound tightly, the end of the last coil can be sewn to the body. To prepare the leveller, soak it in boiled oil for a day and night, then expose it to gentle heat or to the air. The latter is the best if time is not an object. Assuming the circular rubber is so far hardened as to bear grinding down on coarse glass-paper, it can be used on the work, which should be oiled over, and extra fine-ground pumice-stone dusted over it. The pumice-stone powder should be held in a rubber made of two or three thicknesses of fine muslin. When the work looks equally dull and yet retains a polished surface, even and free from nibs when held up to reflected light, it may be assumed to be satisfactory.

It is advisable to level down finally with the round felt-rubber and pumice-stone. The cutting should be as light as possible. It is not necessary to flood the work with oil; a touch here and there will be found all that is necessary. When all inequalities are levelled down, the work is wiped quite clean, free from oil and grit. We shall require a special rubber, with an interior pad of worsted, with three or four coverings of good clean old flannel. Clean old calico rag will do for all coverings, and they should be washed in soda water (hot) to free them from grease. To commence, pour a little polish and spirit on to the rubber, ever aiming at covering the rubber equally so as not to have one part more moist than another.

The first rubbers having now become exhausted, it will be necessary to apply more; but more spirit must be used, which consequently lessens the polish, and that system is pursued until the final replenishings are without polish entirely and less in quantity. To free the surface entirely from grease, the last two or three rubbings may be simply damping the face of the rubber. The *drier* the polished surface becomes—that is to say, freed from oil—the quicker will the evaporation take place, and the more transparent will the smear become, until finally there will be no smear whatever left.

With many polishers it is customary to have three rubbers—one for bodying-in, another for bodying-up, and the first few rubbers in spiriting off, and the flannel rubber, as above explained. We must caution the reader against overflowing the rubber towards the last stage. In fact, if a drop or two is placed in the palm of the left hand and taken up by the rubber, there will be no fear of marking the surface. If all is well, he spiriting off should be clear and bright tas glass, and, not least, should be durable. If any oil remains it must be dried up, otherwise the brightness will not be lasting. The second qualification is that it should stand a moderate heat—above the heat of the hottest day in summer.

The more solid the foundation the surer will the fabric be that is built upon it. More we need not say than that in varnishing the interior cuts of fretwork must be as clean as possible, and that the work must not be drenched with varnish, or it will require double time to get in order.

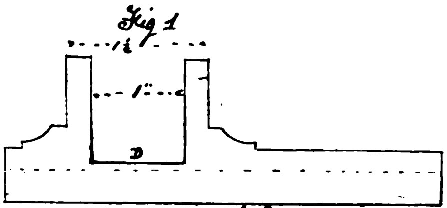
THE END.

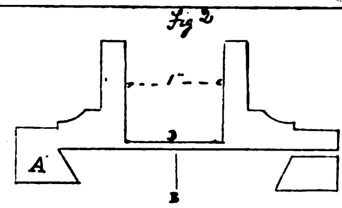
The quantity of coal mined in New South Wales last year was 4,706,251 tons, or 322,660 tons in excess of 1897. The Sydney Harbour Collieries Company are carrying on sinking vigorously at Balmain. It will be some time yet before the coal is reached, which lies some 3,000ft. from the surface.

ORNAMENTAL TURNING.—XXXII.

By J. H. EVANS.

HAVING in my last reached that part of the construction of the spherical slide-rest which constituted the third slide, as attached to its permanent place, although fixed in one sense, it will, of course, be easily recognised that it can be at once removed for any particular purpose that may so require it during the progress of fitting-up the succeeding slide, which works upon it and carries the fourth slide. At the same time, I may point out that the removal of it should be conducted with caution, and as seldom as possible,





as the continued removal of it from the worm-wheel naturally causes the screws to become more or less free in the fitting, and it is desirable that this should be avoided, as it will to some extent influence their holding powers. This will, I think, be so readily seen and acknowledged that it will need no more comment now.

We pass on now to the gunmetal plate which moves upon the slide we have just referred to, and as this has to carry the fourth and final slide, it is provided with a vertical socket, which admits of the tool-box being turned to any angle or position that it is in anyway likely to be required in.

By reference to Fig. 1, a section of the plate and socket, it will be clearly seen how this is constructed. In the first place, a good pattern must be made of the dimensions given, and the casting must then be treated as all the others—that is, planed up and surfaced. By Fig. 2 it will be noticed that in like manner to the preceding slides of a similar character, one angle is cast in the solid with the plate, *vide* A, Fig. 2. Now, there are several points in getting up this socket that will require very careful attention. In the first place, it is absolutely necessary that the centre of the socket should be identical with that of the worm-wheel, which means also the

FIG. 8.

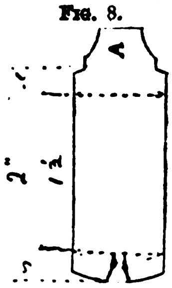


FIG. 4.

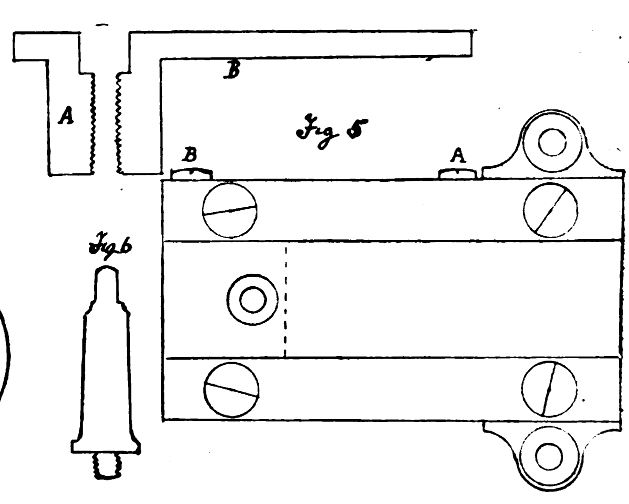

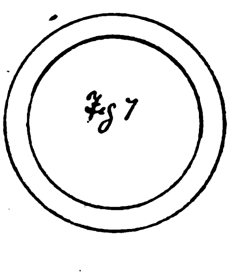

centre of the slide, which is presumably correctly attached to the wheel. This will entail the planning of the angle as follows: We will take, which it really represents, the line B as the centre of the socket. Now, to get this correctly, the distances must be set out with care, and the lines adhered to with equal care.

This, we will take it, has been executed to our satisfaction; but we must remember that when this is so far done, and the slide finished, with the loose strip and set-screws in their places, we still have to bore the hole, and this is another point which must claim our entire attention and thought. We have, of course, the finished surface of the slide as the basis upon which to rely when chucking the plate for the purpose of boring or turning out the hole. There are several ways of chucking or holding such a piece of work for the purpose. It can be held to a surface chuck by clamps and screws; but I think I cannot do better than explain the manner we

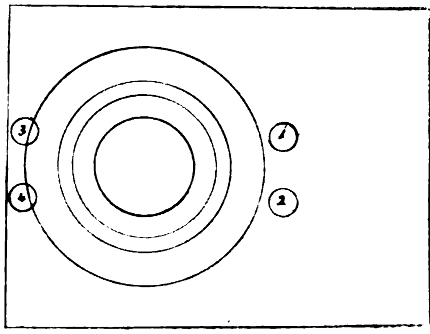

FIG. 3.

have always found the most satisfactory, and, for that matter, the least trouble.

Reference to Fig. 2, the line D, will show the approximate depth to which the fitting should be bored. It may become a question with many, Why not carry the hole through? The fact is, the base thus left forms an important feature for future developments. But at the precise centre a small hole, rather less than 1/16 diameter, must be drilled, and this has two purposes to serve: First, I may say it is impossible to fit the stem required to work in it without a free passage for the air to pass out; secondly, this same hole forms a means of chucking the plate with the desired accuracy. The readiest way to chuck or hold it firmly is upon a metal chuck, the diameter of the face to pass the angle A, and at the centre a small pin is turned to fit the hole, which certifies the centrality. The plate is then carefully soldered to the chuck, when not only can the hole be turned out, but the exterior also turned and finished.

The plate extending on one side of the centre, as it does, when the extension is reached, care must be exercised in the movement of the slide-rest, for the reason that, although perfectly secure for all practical purposes, any sudden jar, caused by a catch of the tool, might tend to alter the position of the work upon the chuck; I say might, because such a thing would probably happen and no harm occur; while at the same time the undesirable alteration is likely to occur.

The external fitting is turned to 1½ diameter, and, as in other similar instances, it is an advantage to have it slightly taper, and it assists in the fitting of the ring which has to be

ultimately fitted to it. The hollow and surface are both, as I have already stated, turned at the same time.

The reason why the socket is made at the end of the plate is that it enables the tool-box which works in it to be brought in closer contact with the work in hand when the slide-rest is in use. I have, I hope, now given a pretty clear insight as to the preparing of this part of the work for the reception of that to follow. Before leaving it, I will explain the meaning of the four holes shown in the plan Fig. 3, marked 1, 2, 3, 4. These, then, are for the purpose of holding the nut in which the main screw of the slide works. We will take 1 and 2 as the position that is most generally used; but at times it is required to create a longer range of movement, and when this is so, the nut is moved forward, so that it may be held to the slide by the holes Nos. 3 and 4, to which the same two screws are transferred. This, it will be seen, will allow the slide, and consequently the tool, to recede quite 2in. or more, which may at times be of great service.

We pass on still further, and this brings us to the steel plate, Fig. 4, upon which the tool-box slides. This plate, it will be noticed in Fig. 4, is provided with a stem in the solid, *vide* A, Fig. 4. The plate must first be carefully surfaced on the top, and by this it is chucked to a true surface chuck, and held by clamps, while the stem A is carefully fitted to the hole or socket. Here again we come to an important fitting; inasmuch as it is necessary that this plate be elevated or depressed according to circumstances, therefore it must not only be well fitted, but must be perfectly cylindrical, so that in whatever position it is placed it will fit equally well. The under surface B must, of course, be turned while the plate is thus held, making one job of it.

We will now return for a moment to explain the reason why the aperture in the metal plate (Figs. 1 and 2) is not bored or turned right through. By referring to D (Figs. 1 and 2) it will be seen that the bottom of the hole is left about $\frac{1}{16}$in. thick, rather more than less. The object is this. By referring to Fig. 4 the section will clearly show that a screw passes through the centre of the stem, the upper part being countersunk or recessed to allow the head to pass freely up and down within its diameter, and at the same time to go well below the surface of the plate in order that the slide or toolbox may not be impeded in its passage over it. It will be obvious that when it is required to make any alteration in the elevation or depression of the height of centre, the said slide must be withdrawn just beyond the recess, so that the key may pass freely into it; this is shown in the dotted line on the plan of plate (Fig. 5). I may mention that the alteration in this respect is a matter so seldom required that very little trouble will be experienced in the adjustment.

The top and final slide is precisely similar to the toolbox made to the ordinary ornamental turning slide-rest, the double-chamfer steel bars being fixed to the plate, as shown in Fig. 5, by two steel screws, the heads of which should be as large as possible, so that the bars are held firmly to the plate. The bar on the right-hand side has the holes slightly elongated to admit of the pressure created by the two set-screws A and B (Fig. 5), moving it forward when adjusting the slide.

The plate, as seen, has, at the end opposite the stem, a projection on each side, which projections are for the purpose of receiving the pillars upon which the lever which actuates the slide rests. The pillars are made similar to Fig. 6, the elongated slot in the lever passing over the top of the pillar. Here again we have exactly the same movement as in the ornamental slide-rest. The base of the pillar should be in diameter just below the curve of the projection; but this is entirely a matter of taste, and may be safely left to the one who is making the slide-rest. Having said that the toolbox not only resembles, but is exactly like that in the ordinary rest, I need say no more on this point. So far, then, we have before us—I hope clearly defined—the manner of fitting up this, the final slide connected with this, I may in all fairness say, complicated tool, or, rather, piece of machinery. We have still another small, although important, matter to look to—viz., we have deliberated upon the fitting of the stem of plate A, Fig. 4, to the socket shown in Figs. 1 and 2; but we have yet to show how this, when fitted, is fixed in the required position. To effect this holding, a steel ring, as illustrated by Figs. 7 and 8, is fitted to the outside of the socket. This again requires considerable care, and the forging should be made of cast steel. When thus fitted and turned to the required width, which will be to correspond with the depth of the socket, it is scarcely possible to give the exact dimensions of this particular part, because it may vary slightly, according to the thickness of the many preceding parts. The diameter of the external fitting is given as $1\frac{1}{4}$in., therefore that of the ring should be about 2in., as shown in Fig. 8.

The ring is centred between the boss A, Fig. 8, and the opposite side, where, it will be seen, it is countersunk to receive a small screw which passes into the socket, to retain it in the necessary position. When the hole in the boss is tapped, and the mouth countersunk, we have it ready to turn, and this forms the next proceeding. The boss should be shaped as shown for preference; but if the taste desire it otherwise, any shape, I need scarcely say, will answer the purpose quite as well.

We must now chuck the ring by the inside, and carefully turn each side down to a slight curve, and perfectly equal. This not only affords a means of obtaining the desired shape, but it also removes a deal of superfluous material, and at the same time gives the distance to guide the file, for it is by this means that it has to be finally shaped. This is a piece of work that will test the abilities of a workman as to his efficiency as a viceman. However, with care it is not a job that should cause any trouble, and if we have effectually reached such a stage, the experience derived will be a great help. When the ring is filled and the screw at the opposite end is in its place, the side of the socket must be marked from the inside of the hole in which the fixing-screw is filled. This done, it must be carefully bored through and a metal plug well filled, but sufficiently free to allow the pressure from the binding screw when tightened to press it forward. The interior of this plug must be made precisely to coincide with the curve of the fitting so that it will bear all round the stem when so clamped. It will be obvious that it would not do to allow the point of the steel screw to bear against the stem; it would become indented and consequently immovable.

We have, now that all else is practically finished, to look to those parts on which it is necessary to have divisions. The steel ring last referred to should be divided into degrees externally, and a steel reader fixed to the underside of the steel plate, the object of this being to enable the tool to be inclined to any definite angle to the right or left of the slide below it, and when so adjusted it is secured by the binding-screw through the ring.

It will be found a great convenience to divide each of the slides into a scale of tenths, and this must be done from the screw; at least, it is preferable to do so. By referring to Fig. 6, Oct. 13, p. 179, it will be clearly seen to which divisions I refer. The readiest and most certain way to divide the slide correctly is to make a cranked tool to fit into the tool-box for the top slide, and to fix a tool of similar character to each of the preceding slides. The starting-point determined, the zero on micrometer must be adjusted, and at each successive turn of the screw the line is marked. The slide may have a steel index fitted, or the division may be read from the edge of the plate. It will be easily recognised that unless these lines are correctly marked, we are better off without them.

It will be a pity, having gone so far, not to have the slide-rest as perfect as it is possible to make it. Therefore, I strongly recommend that each slide is fitted with a pair of fluting stops, which may be made in a similar way to those employed on the ornamental slide-rest. They will be found invaluable in many ways, and form a definite stop, which is so often required in work of a complex character. We have, of course, the means of deciding the length of any traverse by the division I have already explained, but, when once determined and the stop adjusted, much time is saved by the presence of the fluting stop, which is absolute.

I have now completed, as far as possible, the entire details of this, as I have before stated, complicated piece of work; but I feel so certain that all those who have summoned the resolution —and the communications I have received relative to it show that they are not a few—to undertake the task will, in the end, afford a vast deal of interest, amusement, and satisfaction, and I hope all so interested will take advantage of my desire to help in all ways by asking for any further information that may be required. For my next I propose to continue with the necessary tools and manipulation of the slide-rest.

THROUGH A SMALL TELESCOPE.—I.

By NORMAN LATTEY.

REPORTS of observations, comparisons of drawings, and critical examinations of celestial objects, both conspicuous and faint, are constantly being contributed to these columns. To see some of the exquisite sketches that are occasionally sent in by skilled observers, armed with 6in., 8in., 10in., and 12in. reflectors and refractors, is almost enough to make the possessor of a small instrument despair. But he need not. Much valuable work has been, and is being, done with apertures down to 2in. Needless to say, atmospheric conditions and the quality of the

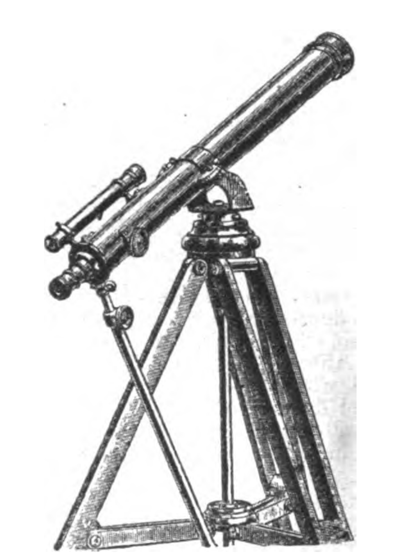

FIG. 1.—Three-Inch Telescope, with Finder, on Tripod Stand, Altazimuth Mount.

lenses, as well as the observer's eye, must all be tolerably good. The writer knows of a refractor but 2in. in aperture, which gives views of the moon in sharper detail than prints of the finest photographs taken at the Lick Observatory; although, of course, the pictures will not bear much enlargement.

It is the purpose of these papers to show what can be done with a small instrument, and by making a systematic survey of the skies with its aid, examine not only the sun and moon at convenient seasons, but also each planet, star, and nebula as it comes into favourable position with the advance of the season. In this wise will the beginner obtain such a general knowledge of the marvels of astronomy as will serve him usefully by way of introduction to more important work later on. Moreover, a few simple directions how, when, and where to look, and what to look for, will enable the student to see more with his humble 3in. than many a casual uninstructed star-gazer boasting superior optical appliances.

Assuming, then, the possession of a telescope of some description together with at least three eyepieces, the only other adjuncts needful as a commencement are:—

(*a*) A star atlas, for the purpose of locating celestial bodies in the same manner as towns and places on the earth are located—viz., by their celestial latitude and longitude, termed in astronomy Right Ascension and Declination.

(*b*) A revolving planisphere, showing at a glance which stars and constellations are above the horizon at any hour of the day or night throughout the year.

(*c*) An elementary work on astronomy, in order to gain a clear conception of the scheme of the universe, and the movements of the heavenly bodies.

(*d*) An astronomical almanac. Klein's Star Atlas, published by the Society for Promoting Christian Knowledge, Northumberland-avenue, W.C., at 7s. 6d., is all that is required to supply the first want, and will invariably be referred to throughout this series. It contains eighteen maps, and charts stars down to $6\frac{1}{2}$ magnitude; besides

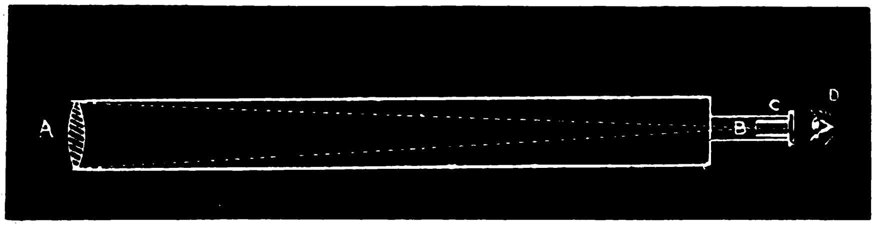

FIG. 2.—Section of a Refracting Telescope showing the Cone of Rays formed by the object-glass.

marking the principal clusters and nebulæ, it also has an extensive explanatory catalogue and several beautiful photographic plates. Messrs. Longmans, however, publish a smaller atlas by the late Mr. R. A. Proctor, at 5s.

By means of the revolving cardboard planisphere, not only are the constellations visible at any particular hour clearly exhibited, but their times of rising, southing, and setting approximately indicated. The publishers, Messrs. Geo. Philip and Son, of 32, Fleet-street, London, send it post free for 2s. 3d. They also issue for 6d. extra an edition printed on tough transparent paper, and fitted with a portable compartment holding a candle, which renders all the stars visible while in use in the open air in the dark.

Sir Norman Lockyer's book "Elementary Lessons in Astronomy," published by Messrs. Macmillan and Co., at 5s. 6d., will suffice the beginner until prepared for more critical works, such as Mee's "Observational Astronomy," Chambers's "Handbook of Astronomy," and Webb's "Celestial Objects," besides various specialised publications of the class of Neison's and Elger's "Moon," &c.

Lastly, *Whitaker's Almanack*, price 1s., *The Companion to the Observatory*, 1s. 6d., and Mee's "Heavens at a Glance," on card, price 6d., will each of them be found extremely useful for the information they give regarding astronomical phenomena generally.

Obviously, the first thing to do is to master the general principles of the telescope, and, by applying this knowledge to your own, see that all the parts are in such accurate adjustment and relation to each other as to insure the instrument performing to its utmost capability.

The main duty of the object-glass (hereafter referred to as the o.g.) is obviously to gather together all the rays of light that fall upon its outer surface at A (in Fig. 2), and to converge them to the point B, where they are received and magnified by the eyepiece (hereafter shortly termed the e.p.) at C, whence they are conveyed in a pencil of light to the observer's eye at D. The enlargement of the bright image so produced will, of course, depend on the power of the e.p., the rules for finding which are given further on.

The accurate "squaring" of the o.g. in relation to the optical axis of the telescope tube is an important matter. It is absolutely necessary that the point of the cone of rays B should strike the exact centre of the larger or field-lens of the e.p., for if there is the slightest tilt the image becomes distorted. The simplest method of ascertaining what the condition of things is in your instrument is to fit in an e.p. of moderate power, and examine a fairly bright star, sharply focussed—the middle star in Orion's belt is as good as any—on a dark, still night. If your o.g. is truly squared, the tiny disc of the star will appear surrounded by flickering hair-like circles of light, called diffraction rings, arranged perfectly concentrically round a well-defined brilliant centre, as at *a*, Fig. 3. If this margin of rings is at all one-sided, as at *b*, or fan-shaped, as at *c*, you should immediately communicate with the maker, or take the o.g. to an optician, for these two last appearances betray some extent of mal-adjustment, and render delicate observation impossible.

A still more certain test, and one which should be tried before all faith in the glass is utterly abandoned, is a similar process to the foregoing, but with the star image *well out of focus*. The diffraction rings will now appear much enlarged and close together, and, if all be well, the illuminated area will be of tolerably equal brightness. If, however, the star's light spreads out into a more or less pear-shaped luminosity instead of into a round patch of mottled and circular-ribbed gold, it means that the edge of the o.g. corresponding to the smaller and brighter side is nearer the e.p. than the opposite one. This happens equally whether the view be within or without the focal point. Should your o.g. be provided with adjusting screws, you can easily correct the obliquity yourself; otherwise the maker or an optician is the safer person to doctor it.

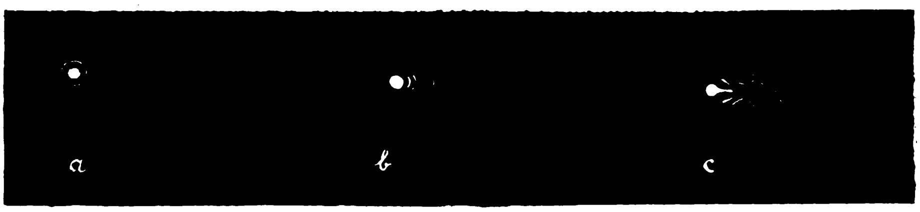

FIG. 3.—Appearances of a Star in Focus when the object-glass is correctly and incorrectly adjusted.

We will now deal with the eyepieces. These should all be of the Huyghenian achromatic type, although a Kellner e.p. of low power gives exquisite map-like views of comparatively large areas. The theoretical limit of magnifying power in a first-class instrument is commonly laid down as 100 diameters for every inch of clear aperture—i.e., a good 3in. should, under perfect atmospheric conditions, be capable of standing a power of 300 on stellar objects, though perhaps rather less on planets. In practice, however, it will be found that 200 on the former and 150 on the latter will be the highest of any real use. This is chiefly owing to varying air currents, aqueous moisture, irregularities in the glass, and other causes unnecessary to go into here. Generally speaking, if with 250 a sharp steady image of a star is given surrounded by neat diffraction rings, you can be perfectly satisfied with your possession.

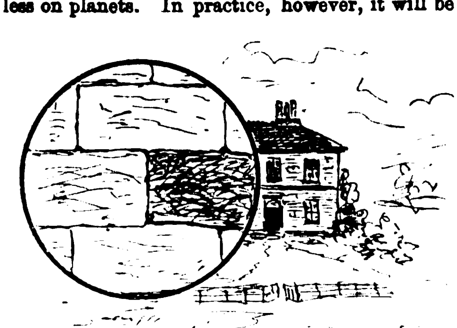

FIG. 4.—The Brick-Wall Method of Determining the Magnifying Power of an Eyepiece.

There are many ways of ascertaining the magnifying power of an eyepiece. The simplest method is to turn the instrument on to a distant brickwall in full daylight. Looking with both eyes wide open, notice with your disengaged eye what height of wall the thickness of a single brick in the telescopic view (which you will see simultaneously with the other eye) covers. Then with the aid of the telescope, count carefully the number of brick courses superposed by the magnified brick, and you will obtain a tolerably accurate notion of how many diameters your e.p. magnifies. A reference to Fig. 4 will make clear the *modus operandi*. It will be observed that the width of the shaded brick in the circular field of view of the telescope extends over the entire height of the wall of the distant cottage—from the ground to the eaves. If, now, this piece of wall is found to actually contain 150 brick courses, that figure may be taken to represent your magnifying power.

You may, however, not have a convenient brick wall at your disposal, in which case adopt another plan. Point the telescope at the sunlit sky, and withdraw a foot or so; you will then see a bright disc just within the e.p. Accurately measure the diameter of this disc with a graduated scale, and divide it into the diameter of the o.g., of which the tiny disc is really an image. The result will be somewhere near the magnifying power of that e.p.; but if you wish to be absolutely exact, the

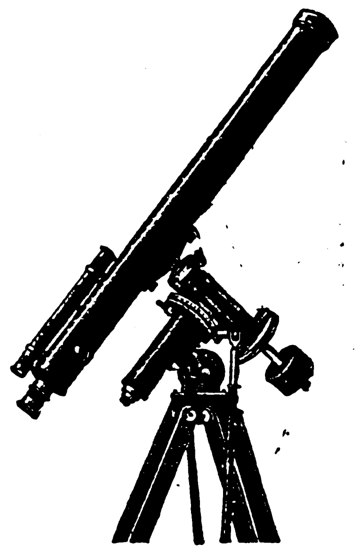

FIG. 5.—Three-Inch Telescope, with Finder, on Tripod Stand, Equatorially Mounted.

following is the usual rule. *The focal length of the o.g. divided by the focal length of the e.p., or the equivalent focus of a compound e p.* (such as a Huyghenian), *yields the magnifying power.* To make the matter quite clear, it may be mentioned that the focal length of the o.g. is the distance from it to the point of sharp focus without an e.p., and the equivalent focus of a compound e.p. is found by dividing twice the product of the focal lengths of the eye- and field-lenses by their sum. For instance, supposing the focus of the larger or field-lens to be 3in., and the eye-lens 1in., then twice 3×1 divided by $3 + 1 = 1\frac{1}{2}$in., the equivalent focus. This, if divided into an o g. of, say, 48in. focal length, would yield a power of 32 diameters.

A word may here be said in regard to the mounting. If you have an equatorial head so much the better, provided, having once found the proper angle and direction of the polar and declination axes, you can always replace the stand in exactly the same position. Full particulars of how to adjust an equatorial have frequently been given in the Correspondence columns. But the labour and patience required is so great, that unless the stand is immovable, or iron shoes for the reception of the legs of the tripod can be fixed permanently in the ground to enable work to be immediately begun without being compelled to occupy several hours on each occasion in re-adjustments, an ordinary altazimuth mount will be found the most handy. Such a one can also be freely moved about when it becomes necessary to dodge an obstructing chimney or tree.

When commencing observations, choose as much of a south aspect as possible, with a fairly open east and west. This will give you command of that belt of sky known as the Ecliptic, within which the sun, moon, and planets restrict their apparently erratic wanderings. Leave your instrument out for half an hour ere settling down to work. A little time is required for the temperature of the lenses and the surrounding air to become equalised. This improves definition and

prevents dewing, that bugbear of all astronomers, professional or amateur. Notice that your finder, if you have one, is accurately set, so that you can pick up the smallest visible object without losing time "sweeping" for it. If you have no finder, look along the top of the tube. With a little practice you will get quite expert, especially if you use a low-power eyepiece to begin with. When the object is found you can, of course, exchange the e.p. for a higher one; but it must be done rapidly, else the star will pass out of your field of view, and may not be so easily caught again.

SOME METEOROLOGICAL INSTRUMENTS AND THEIR USES.—IX.

THE battle of Sedan ended in a torrential downpour of rain, and there are those who suggest that it was the concussion of the air produced by the firing of cannons and muskets that caused the atmosphere to yield up its stores of moisture. An enthusiastic researcher once examined the records giving full accounts of important battles, for the purpose of discovering the kind of weather that followed these engagements, and, by tabulating the number of instances that were followed by heavy rain, he was able to develop a theory, and prove to his own satisfaction, that rain could be brought from the skies by concussion. He was, moreover, able to procure a grant from his Government for the purpose of making experiments in this direction, so that his researches were not in vain. Rainmakers do not flourish so conspicuouly in this country as in many of the American States; but, even here, there are certain theorists who every now and then point out supposed methods by which mankind could gain control of the rain-showers, and so deprive the weather prophets of their occupation. The authority mentioned above, who made his researches in a scientific spirit, and is not to be confounded with the ordinary type of rain-maker, states that during the whole of one celebrated campaign unusual rains, and in many cases unseasonable thunderstorms, followed every battle, and the facts thus collected have given encouragement to the belief that rain could be shaken down, as it were, by the help of detonating shells, or by violent discharges of electricity. Accordingly, few Governments have escaped demands for pecuniary assistance from those who believe that they know best how the thing should be done. Hitherto those in authority have not been eager to place the national armaments at the disposal of the rain-makers, and this notwithstanding that the cost of producing a shower of rain has been estimated at only £10,000—a charge which is not unduly high when the commercial value of, say, ·25in. of rain in times of drought is taken into the account.

It has been suggested that obsolete and abandoned guns might be employed in these rain-making bombardments of the atmosphere, since they are useless for any purpose save that of making a noise and producing rain. There is, however, always the danger that the rain-making might be overdone, and it is on record that certain rain-makers only ceased to claim credit for producing heavy rain and hail-showers when they were threatened with actions at law by those who sought to recover compensation for damage incurred by the unduly excessive rain-making. In passing, it may be remarked that the rain-makers are discredited when it is observed that they are most active when rain is about due, or when it has been forecast by the Weather Office of the country, the rain on these occasions being of course instanced as proof of their skill. It is, moreover, impossible to get rain-makers to agree to any one system of testing their methods, and it need hardly be said that they are adepts at changing their ground when suggestions are made for checking and comparing their records. The advocates of atmospheric concussion as a means of making rain have just now a melancholy opportunity of observing whether explosions of Lyddite shells and other detonating missiles will have any effect in shaking rain from the comparatively dry atmosphere of South Africa, and so provide modern instances of rain out of due season occurring as the result of prolonged bombardments and fusiladings. It is to be feared, however, that war correspondents do not always record these meteorological incidents, and the records, moreover, do not always state the hour when the heavy firing commences, for, in checking the theories of the rain-makers, a note of the time when rain commenced is important. The path of the rain-maker is, therefore, beset with difficulties, and, even if his theory be correct, that prolonged battles and violent concussions and explosions produce unexpected atmospheric disturbances, he has not yet succeeded in persuading the bulk of meteorologists to believe it.

The amount of moisture condensed out of the air either by natural or artificial means is, of course, measured by a rain-gauge, and it is with the records thus obtained that all theories concerning rainfall need to be compared. The work entailed in making rainfall observations as compared with other meteorological investigations, is not difficult, and, since most people appear to be more concerned about rainy days than any other kind of weather, it is not surprising that the rain-gauge is the most popular of meteorological instruments. To obtain a record of the daily amount of rainfall, it is only necessary to visit the gauge once a day, so that when it is fixed in position only a very little experience is required to make the required measurements. It is, however, by no means an easy matter to select a suitable site for a rain-gauge, and since the whole value of the record depends upon this factor, it is worth while to pay a little attention to this part of the subject. Most people are aware that a rain-gauge should be placed on the ground, and in a position where the surface is level, and not shut in by high walls, fences, trees, or buildings. It should also be firmly fixed, so that it cannot be blown down, and, except in those localities where deep snow is frequent, it should be 1ft. above the ground. Any increase in this height will reduce the amount of rain collected, the loss being principally due to the action of the wind which deflects the rain, so that it does not fall directly into the gauge. Were it not for the wind, it is probable that a moderate height above the ground would make no difference to the record. Owing, however, to the fact of the angle at which the wind blows increasing with the height above the ground the roof of a house is considered to be an unsuitable place for a rain-gauge, the records obtained in such situations being further vitiated by the currents and eddies which develop among chimney-pots, and drive the rain in all directions. Undesirable, however, as is a site on a roof, it is sometimes to be preferred to a situation in a small garden surrounded by buildings and overhanging trees.

Further, the use to which the rain-gauge is put necessarily renders it very liable to be deteriorated by rust, and although many gauges are made of galvanised iron, it is wise to increase the pecuniary outlay, and obtain an instrument made of copper. Now during the prevalence of strong winds, the rain-drops bounce and jump about with an increased activity, and many that have no business there find their way into the gauge. To diminish this insplashing the rim of the gauge is made circular and ground to a knife-edge, and this latter not only stops the drops from bouncing into the gauge, but it also splits them with precision, and sends one half inside and ejects the other. The rim is made circular, because it is less likely to lose its shape than if made square; and this rim is about 6in. deep, and is placed around the collecting funnel, the effect of this arrangement being to prevent snow from being blown out when once it has been collected. From the protected funnel the rain or melted snow runs into a storage can, and is subsequently measured in a graduated measuring-glass. As regards this latter, it is not advisable to use it to store the daily rain, for during times of frost it is liable to be broken if water chance to freeze therein. Commonly, most observers find 8 a.m. or 9 a.m. a convenient hour at which to visit their gauge, and since it is probable that most of the collected rain fell during the sixteen hours preceding the previous midnight, it is customary to refer the amount measured to the previous day, the amount measured at 9 a.m. on the 12th, for instance, being entered to the 11th. Experiments show that there is no difference between the indications of a gauge 2in. in diameter and one of 20in., so that the diameter does not matter. The most common diameters in use, however, are 5in. and 8in., and, on the ground of economy, the former size perhaps finds most favour. Seeing that any alteration in the shape of the gauge diminishes the collecting area, it follows that care is necessary to prevent it from damage, a dent in the rim being a thing to avoid. Care as regards the exposure and regularity in respect of the hour of observation are therefore the main considerations in observing rainfall, and if precautions be taken to secure the continuity of the record, the figures obtained may be made to answer many interesting questions.

No part of the world where systematic observations of rainfall have been made have been found to be absolutely rainless, and a rain-gauge erected in even the most arid region succeeds in catching at least an inch of rain during the year. Such areas as the Saharah Desert and certain parts of Arabia are sometimes considered quite rainless; but could a rain-gauge be satisfactorily maintained in these inhospitable regions, it is probable that they also would be found to receive some sort of aqueous precipitation. The term "rain" to the meteorologist, it should be said, includes all kinds of atmospheric moisture that may be collected in a gauge, and in the daily, monthly, or yearly totals of rainfall are counted amounts derived from dew, hoar-frost, fog, mist, snow, and hail. These condensations of moisture, equally with rain, have their effects on soil and vegetation, and no attempt is therefore made to separate them in the gauge. Even therefore supposing rain itself does not actually fall, it is more than likely that the forces of radiation which cool the surface of the earth bring down moisture in other forms, and such localities where this happens are not therefore described as rainless. On examining the rainfall records for any given area, it is seen that the values for stations, only a short distance apart differ considerably from one another; and even for so small an area as a square mile several stations would be required if the average rainfall for the whole area is to be accurately determined. Such an examination also indicates that local geographical conditions are the chief agents in producing diversities in rainfall amounts—conditions which the most expert rain-maker will always find beyond his control, and so pronounced are these effects that in some localities the regimen of the rainfall would only be discovered by a series of gauges separated by distances not exceeding a quarter of a mile.

Now there are, of course, many forces which produce rain; but the greatest effects are to be ascribed to the reduction in temperature brought about by ascending or convection currents of air. The most obvious illustration of this action is to be observed in those onward-moving currents of vapour-laden air which are given a vertical component when they strike against a range of hills or mountains. The convection currents, which are the chief feature in the mechanism of cyclonic storms, are also to be reckoned among the most active rain producers, and in the temperate latitudes nearly all the rainfall may be described as cyclonic. A similar source of rain is to be found in the reduction in atmospheric temperature which occurs during thunderstorms. Another effective cause of rain occurs during the movement of masses of air from the Equator to the Poles, this change of position as regards the sun's rays resulting in an increased radiation from the upper portions of the air, so that clouds are formed and speedy condensation of rain follows. Other prime producers of rain are the moist currents of air which flow in from the sea over the land, and radiate their heat to this cooler area, and in this way lower the temperature of the air to its dew-point, and so bring rain. Now a consideration of these general principles indicates that those who desire to produce rain by artificial means must in some way or other set these convection currents going, and what is required is that the atmosphere should, as the term is, be overturned. Concussion and bombardment of the air have not, as already hinted, been very effective agents in this respect, and a far better motive force would be developed by kindling great fires of an extended area, and thus establish the necessary overturning of the air currents which leads to the condensation of rain. But this method of rain-making is something like Charles Lamb's account of burning a house whenever it was desired to procure roast pig, and has similar economical drawbacks. There would seem, therefore, nothing to be done at present but to continue setting up rain-gauges after the methods mentioned above, and abandon all attempts to tamper with the sources of the rain until more is known of the conditions under which it is produced.

Experiments are being conducted at South Bethlehem, U.S.A., with a plant for producing from hollow ingots seamless steel pipes of large diameter. Pipes of 20in. diameter and ⅜in. thick are said to have already been turned out.

MILLWRIGHT'S WORK.—XX.

THE most favourable conditions for the life of a rope are, after those already named, those in which it always bends in one direction, and in which the pulleys are situated a good distance apart. To return a rope round binder pulleys or round tension pulleys shortens its life by about one-fourth. This is clear, since bending a piece of material in opposite directions alternately stresses it more severely than bending it, and straightening it alternately in one direction only. The farther the sheaves are apart also, the less is the rope strained, because its fibres are bent less frequently; therefore, as with leather, so with ropes, the most favourable and economical method of driving is that in which the pulleys are a

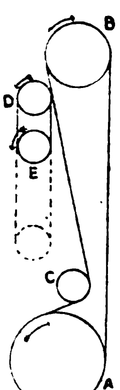

FIG. 128.

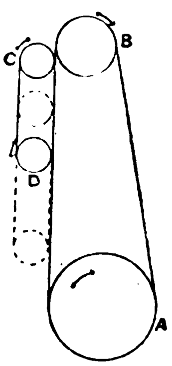

FIG. 129.

reasonable distance apart and the ropes horizontal, with the bottom part of the rope driving, as in Fig. 125. In this figure, *a* shows the sag of the rope on the driving side, and *b* that on the slack side. The amount of these sags, as mentioned in the last article, varies with distance between pulleys, and with speeds. *a* is constant for all speeds at the same centres, *b* varies with speeds at the same centres. Ropes perform best when the sag on both sides approximates to fixed dimensions, which are understood in practice. On long drives the sag amounts to several feet.

There are two ways of using ropes. In one, termed the "multiple" system, a number of separate and independent ropes are employed side by side, each running in its separate groove: in the other, the "tension" system, a single rope is passed round a succession of grooves. The latter is the American, or Dodge system. But though now known as the American, it really originated at Belfast in 1878. The device, however, has not been adopted much here, and in cases where it has been fitted in England, it has been done chiefly, if not wholly, by American firms.

In the tension system, the rope is reeved over the first groove of the first sheave to the first groove of the second sheave, back to the second groove of the first sheeve, and so on until the grooves are all occupied. Thence the rope passes from the last groove of the first sheave to and over the tension sheave. The rope is endless, with but one splice, and the tension allowance for stretch varies with the number of sheaves and their distance apart, and the nature of the atmospheric changes which are likely to occur; ropes exposed to weather requiring a greater range than those which are not. Lengths of from 15ft., to 30ft., or 40ft. in extreme cases, are, therefore, required with varying conditions.

The difference between the two systems of rope driving is very great and important, and each has some advantages over the other.

In the English system, the ropes all being independent have this advantage—that when any single rope requires resplicing or renewal, it can be removed, leaving the remaining ones to do the work, without involving more than a few minutes' stopping of the machinery. On the other hand, there is no such thing as uniformity of tension in all the ropes, for, though they may all commence work alike, in respect of tension, differences become apparent after some amount of service has been accomplished. But, as a set-off, since the ropes run one way, with no return movements, they are in the most favourable condition for durability.

The American single-rope system, on the other hand, has the advantage of equal tension throughout, so that there is no loss of power in consequence of any one section not performing its due share of the work. The rope also is of the same diameter throughout, wearing equally, points which do not hold good of the separate-rope system, in which if some wear more than the others, and if they are not removed, slip, and unsteady driving will result; just as when some stretch more than others, the some results will follow. But against this is to be set off the fact that the use of a single rope introduces the tension pulley, which may also be of too small a diameter, and around which the rope has to make an additional bend in its travel. This bending also often takes place in a direction the reverse to that of the main driving, and therefore distresses a rope by the bending back and forth on itself. But some wonderful results have been accomplished by the single-rope system, and it is used to-day in very many of the largest mills in the United States. Here, again, the problem is one confessedly difficult, which, in the hands of specialists, has attained a high degree of perfection, and many of the drives, in all directions, and to long distance would seem impossible to the old millwrights.

Fig. 126 shows a drive in which one extra bend takes place over the binder pulley A. Fig. 127 illustrates one less favourable still, because the direction of bending of the rope is reversed twice, besides being bent over the binder or tension pulley A. In arranging tension pulleys, therefore, the general method shown in Fig. 126 should be adopted, the rope lasting about one-fourth longer than that in Fig. 127.

The tension on the rope is fixed by the weights B B, Figs. 126, 127, and they are hung to pull on the slack side. The tension varies with the speed of rope, the diameter, and the horse power.

A few typical drives are shown in the succeeding figures, from the practice of the Webster Manufacturing Co., of Chicago. Fig. 128 is an elevator drive, the driving being vertical to a height of 134ft. from the centre of a 14ft. seven-grooved driving pulley, A, to the 9ft. 6in. seven-grooved pulley, B. C is a seven-grooved idler, and D is a one-grooved idler leading to the tension pulley E, which has a vertical movement of 20ft. The power transmitted is 260H.P., with a 1¼in. rope.

Fig. 129 illustrates a vertical transmission of

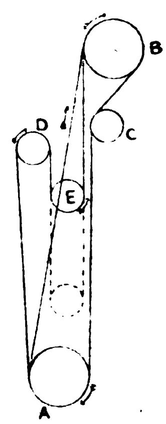

FIG. 130.

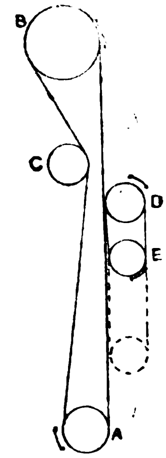

FIG. 131.

900H.P. for an elevator. A 14ft. eighteen-groove pulley, A, drives at a distance of 130ft. away 7ft. 8in. pulley, B. A 4ft. 6in. idler, C, transmits the tension to the pulley D, which has a vertical travel of 40ft. Fig. 130 is another vertical drive from a 9ft. nine-grooved pulley, A, to a 9ft. 7in. pulley, B, 98ft. above. C is the main idler, and D the single-groove idler leading to the tension pulley E, with 18ft. travel.

Fig. 131 is one of the elevator rope drives on the Manchester Ship Canal. A 6ft. nine-grooved driver, A, drives a 9ft. 6in. pulley, 122ft. away, round an idler, C, and a single-grooved idler, D, to the tension pulley E, having a travel of 25ft.

J. H.

THE EXPLOSIVE FEATURES OF ACETYLENE.

THE rapidly extending use of acetylene and the fact that its widening range of application is putting it increasingly into unskilled hands, render the question of its explosive properties a vital one to the community at large. In the earlier stages of its manufacture and use, the new illuminant suffered somewhat in reputation from the recurrence of explosions more or less destructive and fatal, and there was for a while a danger of its field of usefulness being narrowed by a popular fear as to its safety out of proportion to the facts. Thanks, however, says the *Scientific American*, to exhaustive experimental work in the laboratory, the explosive possibilities of acetylene have been determined with accuracy, and it is now possible to manufacture, transport, and use the new illuminant with something of the same immunity from accident that characterises the familiar coal-gas.

Pure acetylene gas, when under atmospheric pressure, is not explosive. This was proved by Berthelot and Vieille before acetylene was looked upon as having commercial value, and as soon as its production on a commercial scale became certain, they took up the question again and confirmed their earlier experiments with the following statement: "Under atmospheric pressure and at a constant pressure, acetylene does not propagate to an appreciable distance decomposition provoked at any point. Neither the electric spark nor the presence of an incandescent wire, not even the detonation of a fulminate primer, exercises any action beyond the vicinity of the region subjected directly to the heating or shock."

As the pressure of the gas rises above that of the atmosphere, it becomes liable to explode, but it is not possible to state the exact critical pressure above which a definite exciting cause will, and below which it will not, render acetylene explosive. Berthelot and Vieille state that when the exciting

cause is an incandescent wire in the gas, the maximum allowable pressure is 10·5lb. gauge, and when the cause is the detonation of a fulminate cap 3·5lb. is the limit. These two causes of explosion were taken as representing the extreme conditions that could obtain in faulty manufacture and manipulation of the gas, the first representing intense local heating in calcium carbide attacked by a small amount of water, or caused by intense friction due to the rush of gas through a valve. The second case, which would be represented in the formation and detonation of acetylides, is not liable to occur in the commercial production of acetylene, but could only happen under special laboratory conditions.

Liquid acetylene, therefore, on account of its condensed state, is naturally susceptible to explosion, detonation being caused by high temperatures, sparks, or heavy shocks to the liquid itself. Berthelot detonated a steel bomb filled with liquefied acetylene by means of an incandescent wire, the crusher gauge showing a pressure of 5 383 atmospheres; but liquefied acetylene contained in cylinders was shown by the same experimentalist to be proof against detonation by shock, a cylinder charged with 300 grammes of the liquid falling repeatedly upon a steel block from a height of 19·5ft. without explosion. A direct blow upon the liquid itself may heat a small portion to a dangerous temperature, whereas the same blow to the cylinder would be only partially transmitted, and what portion did reach the liquid would be absorbed by the whole liquid mass. A real peril exists at the cylinder and reducing valves, due to the sudden arrest of the column of gas at the reducing valve, raising its temperature adiabatically to the explosion point.

Acetylene is more dangerous than illuminating gas in forming explosive mixtures with air, for not only is the ignition temperature lower, but the explosive energy is greater, and the range of the explosive proportions of the gas and air is wider. Thus a mixture of one volume of illuminating gas with one or with two volumes of air will not burn; whereas a mixture of similar proportions of acetylene gas and air burns with a sooty flame. In the case of each gas a mixture of one volume of the gas to three of the air is explosive. The strongest explosive in the case of acetylene is one to nine, and in the case of illuminating gas one to six. But whereas the latter ceases to explode at one to twelve, acetylene mixtures do not become non-explosive until the proportion is one to twenty. The temperature of ignition varies but little with the proportions of the mixture, and is placed at 900° F. for acetylene as against 1,100° F. for most combustible gases.

MECHANICAL TRACTION FOR CANALS.

WITH the general interest which exists in the development of internal waterways in Central Europe there has also arisen an activity in devising substitutes for animal traction. The entire subject of mechanical traction in connection with internal navigation is treated exhaustively in a paper by M. Galliot in the *Revue de Mécanique*, while the application of electric traction to canals is discussed at length in a paper in the *Elektrotechnische Zeitschrift* by Herr G. Klingenberg.

As a matter of fact, the present system of animal traction is most primitive, there having been little or no improvement since the most remote times, and although nearly a century has elapsed since the application of steam-power to navigation, we still see boats hauled along the canals by horses, mules, and even by men.

It is largely on this account that canal navigation has been regarded by some as a system of transport which is gradually becoming obsolete, and which is destined to be superseded entirely by railways; but when we consider that in many cases the canals have been acquired by the railways in order to divert the traffic, and consider the utter neglect which has, until recently been shown towards the older method of transport, we see how mistaken an opinion may be when it is based upon such peculiar conditions.

Apart from any system which merely involves the use of steam tow-boats, the methods which have been seriously applied to canal service may be divided into three classes; (1) screw propellers, fitted to the boats themselves, (2) chain or cable towage, operating by power-driven drums on the boats, and (3) electrical towing machines running on the tow-path or on a track by the canal, and hauling the boat by tow-line.

The use of screw propulsion is one which naturally suggests itself when the question is brought to the notice of the general observer, but the peculiar conditions attending canal transport have rendered it difficult to make a satisfactory solution of the problem in this manner. In the first place it is very desirable that no important change be made in the construction of the thousands of existing canal boats, and so it is hardly practicable to instal an entire engine, boiler, and screw equipment upon each boat, especially since this would detract materially from the carrying capacity. This difficulty has been met by placing a motor in a sort of a box rudder and connecting it directly with a propeller projecting from the rudder. The high speed of the electric motor enables a small propeller to be used, and the electric current can either be taken from a feed-wire running along the bank, or be produced by a small engine and generator standing on the deck of the boat.

While the idea of placing the power in the rudder, first suggested by M. Trouvé, avoids the cutting of the boat and renders the old boats available, yet it possesses the disadvantage of so lengthening the boat as to interfere with the passage through locks, and in many cases the time lost by unshipping and reshipping the rudder is sufficient to condemn the apparatus. The clumsy shape of the stern of the boats as now made also renders it difficult to attain speed, owing to the wake, which causes the propeller to draw air and lose in power and efficiency.

The use of fixed cables or chains in connection with power-driven drums on the boats, is a very old idea, and has been used with some success, especially on the Rhine, where heavy chain towage is still in regular operation; but this system is hardly applicable to the great bulk of canal transport, and must always be limited to motor-boats hauling heavy trains of canal barges behind them. Few, if any, installations of this kind are now being made, and they are very unlikely to come into future extended use.

In all probability the third method, that of haulage by some form of travelling machine running along the bank, offers the best prospect of success, both from a mechanical and a commercial point of view. This method includes not only hauling machines acting by direct towage, but also running cables to which the boats may be connected and disconnected. Running cables have been a subject of experiment since 1869, when a patent was taken out by MM. Troll and Mercier, and since then numerous modifications have been made, principally in connection with the supports and grips, but in spite of the perfection to which these details have been brought, this form of canal towage has not been found acceptable.

Towing machines running along the path have been quite successfully mechanically, and several forms of these are now in use. The first of this kind dates back to 1839, and was devised by M. Larmanjat. In this case a steam traction-engine was used, there being a single rail to act as a guide, while the weight of the machine was carried by large wheels running on the tow-path, but the cost of operation at that early date prevented the system from coming into use.

The same idea, using electricity, has now been revived in France by M. Galliot himself, and in Germany by Siemens and Halske, the principal difference between the two systems being that the first uses a machine which runs on the ordinary tow-path, while the latter requires a narrow-guage railway by the side of the canal. Both of these systems are now in actual use, that of M. Galliot being introduced by MM. Denèfle et Cie on the canals of the Aire and the Deule, in France, and that of Siemens and Halske on the Finow Kanal in Prussia. In the first case there is a separate machine for each boat, the whole apparatus weighing about two tons, and being capable of exerting a uniform tractive power of 1,000lb., or an emergency pull of a ton. The machine is controlled by an operator who rides upon it, and steers it as well. The principal objection which was urged against a machine running upon the tow-path was the possible damage to the roadway; but with the wide-rimmed wheels, and a properly-made road, it is found that there is less injury to the path by the machines than from the horses. Since the power is taken by a trolley-pole from an overhead wire there is no interference whatever with the path for animal traction, and the system can be gradually introduced in connection with the older plant, and no change whatever is needed in the boats.

The Siemens and Halske system is suitable for hauling trains of barges, and is intended to supplant horse traction entirely, and, while it will doubtless be an entire mechanical success, it is much more costly in installation.

The crucial question of commercial economy has yet to be settled, and cannot be decided until after a prolonged trial under actual operative conditions; but there is every reason to believe that if success is attained it will be along the lines of the last two systems.—*Engineering Magazine.*

AN ENDSHAKING TOOL.*

I SHOULD be glad to give the name of the inventor of the tool described in the following article if I could, but it dates too far back in watchmaking history for me to locate its origin. The "Arkansaw traveller" asked the old settler how long he had been there, and, pointing to the distant trees, he replied: "They woz here when I kum."

So this particular tool, with a few others, such as the jewelling rest, wigwag polisher, &c., started in the early days of American watchmaking, and I believe have never been displaced nor substantially improved upon by more recent appliances for the same work. As illustrating a valuable principle in gauging or measuring tools, I trust it will be of interest, not only to watchmakers, but to others who might use the device in other lines of work.

To explain, then, at the outset what is meant by endshaking, I will refer to Fig. 1, in which L is a pinion in a train of watch-wheels. A and B are the shoulders of the same resting in the jewels C C. The allowance made for this pinion to move freely endways between these jewels is called the endshake, and the tool illustrated in Figs. 2 and 3 is called a pillar-plate endshaking tool, as it finds the distance between the jewel-setting seat in the pillar-plate and the face of the jewel inside of the top plate, and also the cut required on the jewel-setting shoulder to give the proper distance for any opinion, including its endshake, that is selected to run in the watch movement to be measured.

The general appearance of the tool is shown in

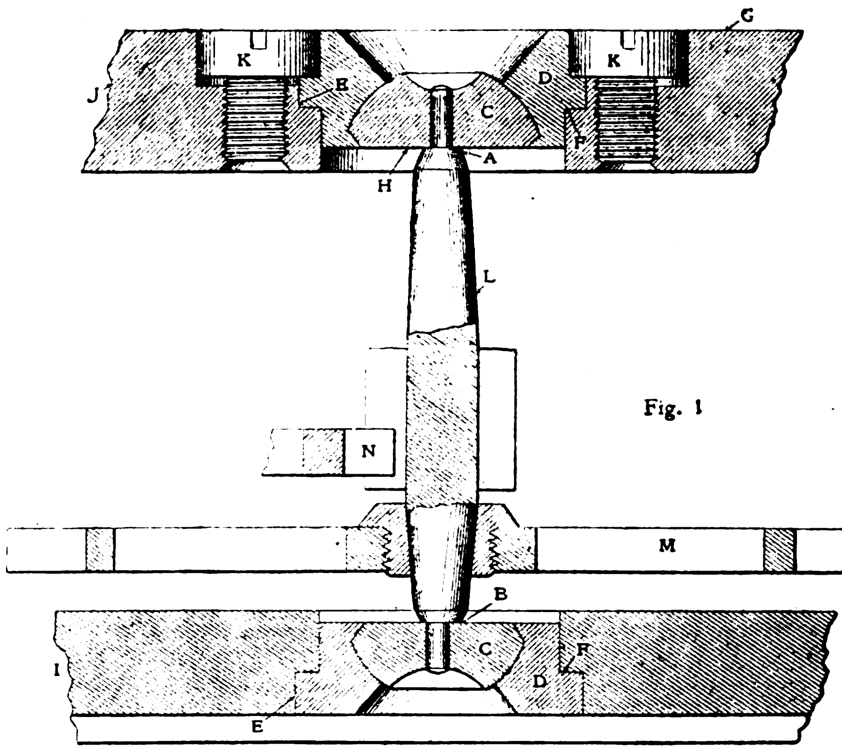

Fig. 1

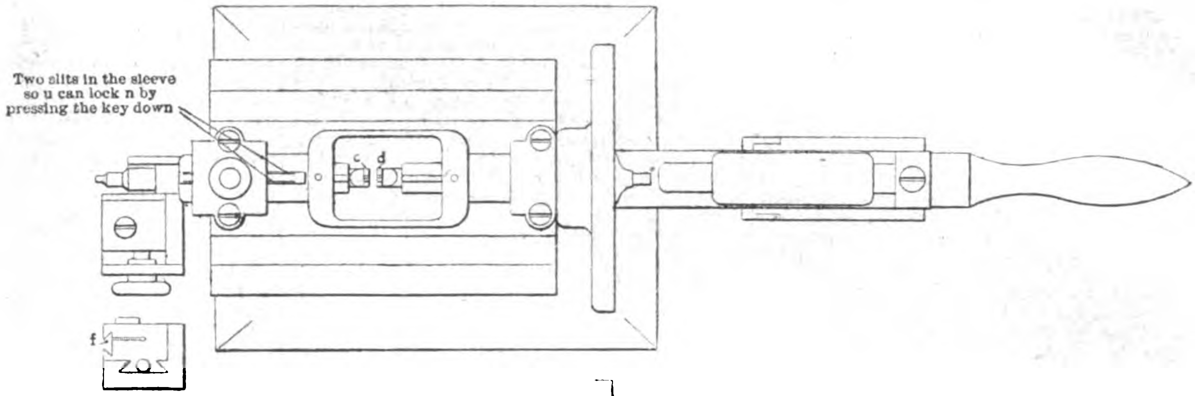
* By A. H. CLEAVES, in *American Machinist.*



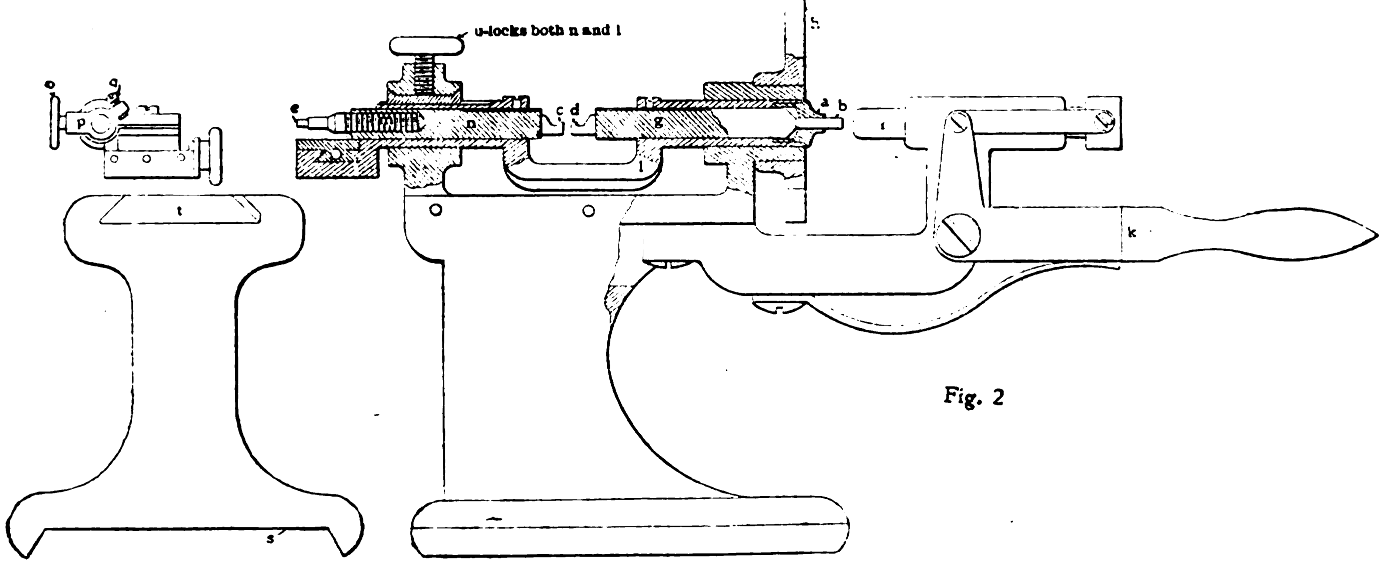


Fig. 2

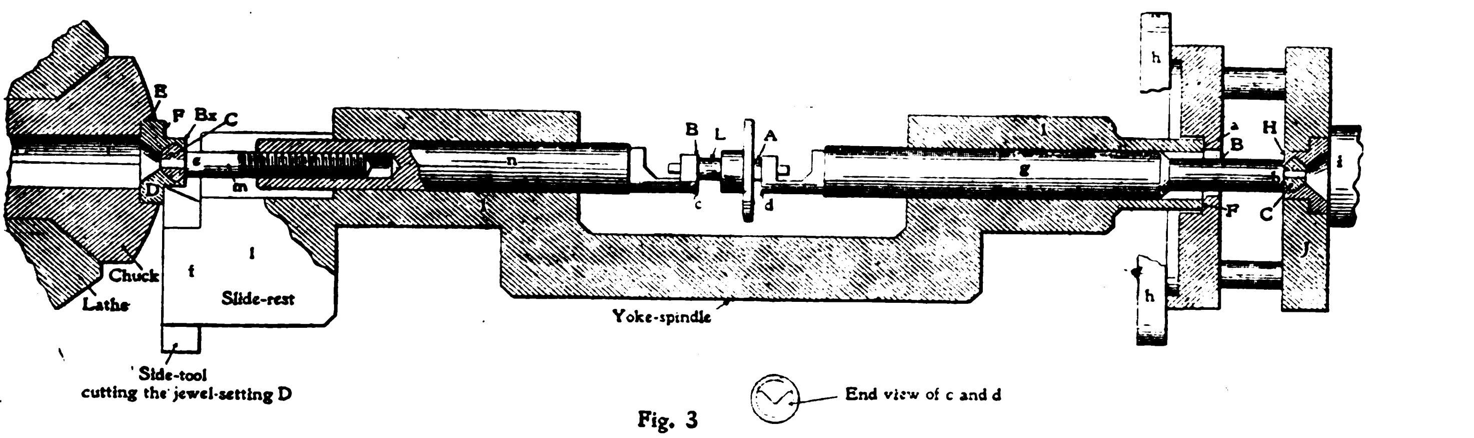

Fig. 3

Fig. 2, while Fig. 3 is an enlarged view of its working parts, showing the method of use. The point *b* of the spindle *g* is brought against the face H of the jewel C of Fig. 1, as shown in Fig. 3, in which the frame of the movement is shown in section, being held against the plate *h* by the tail spindle *i*. Spindle *i* is kept in position by the spring *j* (Fig. 2), a handle *k* being provided to draw back the spindle when inserting or taking out a movement. The shell point *a* of the hollow yoke spindle *l* is brought against the sink shoulder F (Fig. 1) of the pillar-plate. As will be seen from Fig. 3, the two tips *a* and *b* measure the distance between H and F of Fig. 1, which, supposing no endshake, is obviously equal to the distance A B of the pinion plus the B F of the jewel.

The work done by the tool is the cutting of the shoulder from B to F on D (Fig. 1), the latter being held at E (Fig. 3) in a spring chuck running in a lathe. The cutter for this is held in the little slide-rest *f* (Figs. 2 and 3), shown in numerous views, and which is a part of the yoke spindle *l*.

Let *a*, *b*, and *i* be brought together, also the points *c d*, and let the point *e* and the tool *f* be adjusted to be flush with each other. Then if the movement be inserted as in Fig. 3, and any pinion picked up at random be placed in the fork-rests *c d* (Fig. 3), the shoulders A B of the pinion L (Fig. 1) resting against the ends of the forks *c d*, it is plain that the distance between B and F (Fig. 3) will be the difference between the distances A F and A B, or B F (Fig. 1); that is, the tool *f* will be advanced beyond the spindle *e* the amount of the cut on D to give no endshake.

To get the endshake the sub-spindle *m* in the spindle *n* is threaded and provided with a collar, *p*, a thumb-screw, *o*, and an adjusting-screw, *q*, as shown in the end view of Fig. 2, and the adjustment of the tool to give a cut to the jewel-setting which shall provide endshake to the pinion is made by setting *m* forward of the cutter by the adjusting-screw *q*. It will be seen that setting *m* forward gives a less depth of cut to the jewel-setting, by which it is prevented from going so far into the pillar-plate, and thus provides the needed endshake. The base of the tool fits into a lathe-bed at *s* as a tail stock. The whole measuring apparatus is locked when ready by thumb-screw *u*, and slides up to work in the guide-bed *t* until *e* reaches C at B *x*. Open bearings are used to admit the yoke spindle *l*, which, together with *g* and *n* are provided with keyways to prevent revolving. If the thread on *m* is right-hand, the stop-screw is used before the collar in getting the endshake.

A BELGIAN royal decree has approved the resolution of the Provincial Council of Brabant, fixing an annual tax, after January 1st, 1900, on all automobiles. The tax will be 15s. for an automobile weighing less than 880lb., and vehicles which weigh more will pay 40s. per annum.

PETROLEUM AND ITS PRODUCTS.*

PETROLEUM is one of the most wonderful natural substances gotten from the earth. The most generally-accepted theory of its origin is that it is a sort of mineralised animal-vegetable oil, the result of decomposition of animal and vegetable matter beneath the surface of the earth. The same vegetation that produced the coal may have, under different circumstances and conditions, tended greatly to the production of petroleum. The multiplicity of materials procured from petroleum, and the uses to which they are put, is far beyond the limits of the most enthusiastic friend of the oil a few years ago.

Petroleums vary much in appearance and make-up, some are light coloured, some dark, some thin, some thick, some heavy in bitumen and short in light oils, and some the opposite. Some are easy to handle in refining and readily fall to pieces when heat is applied, others are very difficult to handle, and if not complex in composition, are at any rate very hard to refine.

Some contain so much bitumen as to be worthless for any other purpose. I very well remember years ago to have seen, bubbling from the mountain sides in Southern California, little springs of warm fluid, clear as crystal, which was a bituminous petroleum. So heavy was this with bitumen that within, say a thousand feet from where it bubbled forth clear

* By W. J. SANBORN, in *Popular Science News*, N.Y.

and sparkling, it was entirely deposited in a black bitumen paving the mountain roads along which it slowly flowed. The easiest of all the petroleums to refine is the Pennsylvania crude. The proportion of light oils is large, and the amount or residuum and bituminous matter small; simply a straight heat breaks the oil up into its fractions.

The ordinary course of refining for such oils is by means of the cylinder still. Such is usually about 12ft. in diameter and some 30ft. long, of about 600 barrels capacity. The still is set in brick, and looks, in a way, not unlike a big boiler; on the top is a drum-shaped dome, from which a large pipe, more than 1ft. in diameter, passes to the condensing apparatus. The oil is distilled by a fire heat or by a combination of fire heat and super-heated steam. The distillation is a fractional one, and the number of fractions taken off depends upon the oil, the refiner, the conditions and demands.

With the fires under the still—there may be a string of stills from three to twenty or more, according to the capacity of the refinery—and the heat beginning to be felt, the distillate begins to come off. From the condensing apparatus are pipes leading to various big tanks. The first of these pipes to be opened is the one leading to the naphtha tank, as that is the lightest product and the first to be vapourised. The vapour passes into the condensers, is there chilled to oil, and flows to its respective tank.

The specific gravity of this distillate is frequently taken, and when it falls below 0·760 to 0·780, according to circumstances and desires of the refiners, the pipe is closed, and the next distillate is then run into the burning-oil tanks for kerosenes. In other words, all that comes off down to, say, 0·780 is naphtha. The gravity is still watched, and when it reaches the point which the refiners wish, which varies according to conditions, the pipe is closed and all the light oils are off.

From this point forward the process varies with the products desired. All that is left in the stills may be considered as a residuum and put in other styles of sills, subject to a heat of 550° Fahr., with a hot-air blast for about a week. At the end of that time it comes out a thick viscid black matter, which, when cooled, resembles asphaltum, and is used for roofing and paving purposes, for making tar paper, quick-drying black varnish, such as go under the name of "asphaltum" varnishes, and for many other purposes.

Instead of drawing off what is left in the still after the light oils have come off, the balance may be treated to bring off lubricating oils. This will require a much different process. In fact, after the light oils are off, the treatment varies for the product required. It varies, too, as to the processes when more or less of this or that product is required.

If the ordinary distillation is followed after the light oils come off, it will be much on these lines. The degree of heat will be increased gradually, and a heavier oil will be vapourised; this is known as neutral oil, being neither a burning oil nor a paraffin, but neutral to each. After the gravity has shown that all of this oil has passed over, the next oil to come off will be the paraffin-oil from which the paraffin-wax is taken. When this oil is off, all that is left is black oil, tar, still-wax, and coke; these are separated out as the requirements of the refiner may indicate. Black oil is the commonest, cheapest kind of lubricating oil; still-wax is used for many purposes, among them the lubricating of elevator wire ropes, wire cables for cable-car lines, curve grease for street-car lines, and such purposes.

Petroleum coke is a very hard material, especially rich in carbon, and until lately has been used in immense quantities for making carbon pencils for the millions of electric arc-lights. Now it is sold by the ton for fuel, suitable for stoves and furnaces in houses, or burned at the refineries. As a fuel it produces great heat and no ash.

The principal oils that have now come off are naphthas, kerosenes, neutrals, and paraffines. Each oil in its turn is redistilled and separated into other fractions, purified, bleached, debloomed, and passes through many processes, quite too numerous to mention in any short article.

From the naphthas are separated gasolines, for stoves and gas machines, varnish, naphtha, and sometimes other goods. From the burning-oil tanks come various grades of burning oils, oils of varying fire-tests, colours, and degrees of gravity or weights. So down through the list. From the paraffine oils comes the wax known by that name. This wax, in its crude state called "scale," is of a yellow colour, quite hard and brittle, and passes through many processes to refine, bleach and soften or harden, as the requirements may be, before it is fit for the market. Ultimately tons of it reach us through the confectioners and chewing-gum makers, but the great use to which it is put is in candle-making. In the purification of these oils are used hundreds of tons of chloride of lime, fullers' earth, oxide of lead, sulphur, sulphuric acid, bone black or bone charcoal, salt, and other chemicals.

Vaseline, petroleum jelly, and petrolatum are fancy names among the 50 or more given to a product known to the refiners as petrolatum. In pumping oil from the wells in the oil regions, there gathers about the pump-rods a material of a semi-waxy nature, called rod-wax. This, when filtered through bone black or bone charcoal, becomes clarified and lightened in colour, and if filtered enough will become perfectly white, and is the petrolatum of commerce. The colour and price depends very largely upon the number of times it is filtered. It is used for a thousand and one purposes, and is found in almost every house in the land.

There is very little loss, almost none, of material in petroleum refining, everything is used for something, save perhaps the residuum from the clarification of the distillates with acid, which material is known as sludge-acid. Even this is now used successfully for the manufacture of insulating coatings for electric wires and like purposes.

Petroleum is the source from which this country now gets all its mineral oil. The bulk of all lubricating oils, as well as the base-oil for all greases, from the waggon grease, the car-wheel grease, to the lubricating stick for the chains of bicycles, comes from this same great supply-source. The oil for the sewing-machine, for the reaper in the harvest field, and the loom in the factory, are petroleums. The candle, the electric light carbon, the pintsch gas of the railway coach, the chewing-gum, the paint on the house, likewise the varnish on the furniture, the "asphaltum" roof on the factory, and the paving in the street, some of them all, and some more or less, come from the same great head—petroleum. In the preparation and making of the very cloth on our backs we are indebted to the same, for thousands of barrels of petroleum under the name of wool oil are used for treating the wool.

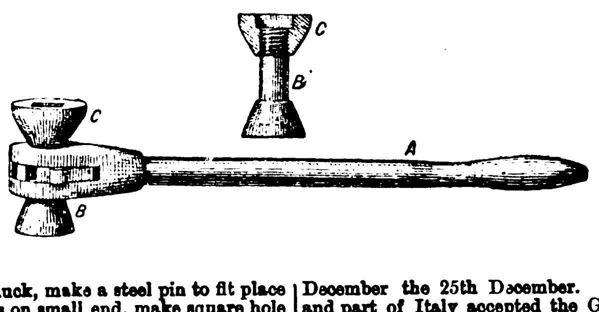
Petroleum in one form or another is used by us from the cradle—and before—to the grave, from the doctor and surgeon to the undertaker and embalmer. It is the great "dust layer" for the floors of our houses, stores, factories, and public halls, village streets, country roads and railway tracks. It will deaden one surface and polish another. It is a germicide, an insecticide, and is being used as a disinfectant.

Petroleum has an extensive use in all it forms and phases as an adulterant, whether it be as naphtha, kerosene, or any of the other oils, or as wax; millions of gallons and thousands of tons are used for direct adulteration of more expensive products.

All in all it is a difficult thing to say where the world would be to-day were it taken from us. Yet many of us did exist for several moons before it was known; for all of that it is to-day one of the greatest products of the age and world.

HANDY RATCHET WRENCH.

THE handy wrench shown in the annexed engravings is described in the *Blacksmith and Wheelwright* by Mr. G. W. Hart, of Angola, Kansas, who illustrates it as a handy ratchet wrench for taking off tire-bolts, with taps in two sizes. Take an old ratchet brace, cut off and weld end at A. Take out chuck, make a steel pin to fit place like B; cut threads on small end, make square hole in large end to fit waggon-tire bolts. Then make small pin like C, drill hole clear through, make large end square, cut thread in small end, and put together. Screw C on tight, rivet with punch, put key through ratchet cog, and you have a very handy wrench. I took the chuck to put in my post drill.



CASTING BLOCK-TIN TUBES.

OF the inventive ingenuity of Eli Whitney, the famous inventor of the cotton-gin, Prof. Silliman, in some reminiscences published in 1846, cites several interesting examples. In the summer of 1808, for instance, he tells, Whitney was applied to for tubes of block tin, for the purpose of drawing through an innocuous metal the soda-water, highly charged with carbonic acid gas, which was then just beginning to be known. Lead and copper tubes were rejected on account of their poisonous properties, and there were then no facilities in the United States for constructing the tubes that were desired. Whitney accomplished the object with his usual precision. The tubes were required to be many feet long, and strong enough to resist a heavy pressure. He caused a mould to be constructed of cast brass, in two parts, each containing, for about 2ft. in length, one-half of the cylindrical cavity corresponding to the desired tube. When the parts of the mould were accurately fitted and screwed together, they contained the entire cylindrical cavity between them, and to secure the duct through the tube a polished steel rod, of the proper size, and made very slightly tapering, was fixed in the centre and the melted metal was cast round it; the rod, being terminated by a ring, was easily knocked out. The separate parts of the tube thus produced were then joined into one, by having the contiguous ends of two of them brought longitudinally into contact, and included in another mould, containing an enlarged cavity, into which melted tin was poured. The duct was preserved by a steel rod passing through it as before, and thus the joint was perfected by a knob of metal which at once united the two tubes into one, and gave them great additional strength. Whitney did not state that this method was original, but up to that time there had, so far as is known, been no similar method of casting block-tin tubes.—*Cassier's Magazine.*

SUBTLETIES OF THE CALENDAR.

AMONGST reasonable people there is by this time an approximate unanimity of opinion as to the true date of the demise of the nineteenth century and the commencement of the twentieth. But there are some subtleties or eccentricities of the Calendar which may be edifyingly stated in the face of the advancing year 1900, which, with the other years marking the conclusion of a century since 1600, is to be reckoned as an ordinary year in contradistinction from a Leap Year to the dignity and length of which its divisibility by four would seem to promote it. At the time of the introduction of the Julian Calendar the Vernal Equinox fell on the 25th March, to the 21st of which it had retrograded at the time of the Council of Nice, A.D. 325, until on the eve of the reformation of the calendar by Pope Gregory XIII., it occurred so early as the 11th of the same month. In order to restore it to its proper place, the Pope, who was assisted in his enterprise by Lilio, an able astronomer of Rome, directed the suppression of ten days in the calendar; and as the use of the Julian intercalation resulted in a redundancy of three days in 400 years, he ordered the said intercalation to be omitted in all the centenary years except those which were multiples of 400. According to Gregorian rule, therefore, every year of which the number is divisible by four, without a remainder, is a leap year, excepting the centenary years which are leap years only when divisible by four, on suppressing the units and tens. Thus 16(00) and 20(00) are leap years, whilst 17(00), 18(00), and 19(00) are ordinary years. The shifting of days caused great disturbance in festivals dependent on Easter. Pope Gregory, in 1582, ordered the 5th October to be called the 15th October; the Low Countries made the 15th December the 25th December. Spain, Portugal, and part of Italy accepted the Gregorian change, but the Protestant countries and communities resisted up to 1700. In this country the ten days' difference had increased to eleven days, and the Act of 24 George II. was passed to equalise the style in Great Britain and Ireland to the method now in use in all Christian countries except Russia, and amongst some Oriental communities. In England, Wednesday, September 2nd, 1752, was followed by Thursday, the 14th September, and the New Style date of Easter-day came into use in 1753.—*Echo.*

THE iron deposits in the Transvaal have not yet been thoroughly exploited, owing to a concession granted in 1883, which prevents others from starting ironworks.

IN connection with the anæsthetic effects of the electric current, it is stated that with a current of 28,000 alternations per second passing between the elbow and the hand, a needle can be painlessly run into the forearm.

ENLARGING APPARATUS.*

AS will be seen in Fig. 1, the body is made box shape, the sides and front of which should be made preferably of hard wood, to prevent splitting with the heat. I have made mine of ½in. oak, which, when planed down, gave me ⅜in. fully, and the bottom out of ⅝in. white wood.

Procuring our timber, we proceed to prepare the pieces necessary for the body. Having planed the wood, we saw out a piece 9½in. by 10in. from the white wood to form base, and plane down to 9in. by 9½in.; this will give a projecting piece each side of the sides of body of about ¼in., Fig. 2.

Then, with the tenon-saw, cut two grooves about ¼in. deep the full length of base, to receive the two sides, the outside cut to be ¼in. from each edge of board, to give the two ¼in. projections at side, as shown at Fig. 2; these grooves can be chiselled out.

Now, out of the hard wood, cut two pieces 12½in. by 9½in., and plane down to 12¼in. by 9in.; these will form the two sides. A piece of hard wood is now required for the front, and, to make this, cut a piece 12⅝in. by 9⅝in. and plane down to the required size to suit the width of body and thickness of base. The mode of fixing up the body will be apparent to the worker. The two sides are glued and screwed into the two grooves, and the front board is fitted on flush over all from the bottom of base, Fig. 3. The top must now have consideration, and must be made of metal. I use a piece of zinc, and, to prevent any injury to the woodwork, have placed a layer of sheet asbestos round the top edges of sides and front before screwing on the top; dirty cuttings of this can be bought at most engineers' stores, sufficient for the purpose, for a few pence.

It is, of course, necessary to have a ventilator in the top.

Before fixing front board it is necessary to cut a circular hole in it to receive condenser, the diameter of which is governed, of course, by the size of condenser it is decided to use. If expense is a consideration, as it was in my case, buy a 4in. dia., which can also be bought at Benetfink's for 5s. 6d. I fancy I hear someone say, "What is the use of that size for a ¼-plate?" Wait a bit, though, and I will tell you. It is not always required to enlarge the whole of the plate, and, should it be necessary at any time to cover the whole of the plate, it is a matter very easily got over by making a decent print and then copying it, reducing the negative to a size suitable to the compass of your condenser. Having fixed up, the door must next be thought about, and this I have placed at the back, as stray light can best be guarded against there, forming the hinges out of two screws.

Before fixing on the metal top it would be as well to try the condenser, to see whether it is held rigid enough in the front board. If not, screw a thick piece of wood inside the body, cut to the sweep of the brass body of condenser, as seen in Fig. 5. This will form a bed for it to rest in. To complete the body it is necessary to fit two angle-pieces along the two undersides of case, to receive the sliding base, that will presently be described, seen in Fig. 6, and two pieces of wood on the front of body, immediately over and under condenser-hole, to enable the carrier to slide in between easily, as shown in illustration, the thickness being governed by the thickness of carrier. We are now ready to proceed with the sliding-front arrangement, which consists, as will be seen from illustration, of a bellows attached to a back and front board, after the style of a camera. The bellows I have in use is one that is described in Benetfink's catalogue as "No. 13, parallel 7⅜in. by 7⅜in., 14 pulls in," price 1s. 7d., and is glued at one end to a piece of wood measuring 8½in. by 8½in., having a hole cut in it larger than the condenser, this piece being screwed to the front of body as shown; the other end is glued to the front board that carries lens. This piece measures 12in. by 8in., and is fitted, as will be noticed, with a rising and falling front—a very useful addition. The sliding front of camera may be used for this, making the grooves out of cigar-box wood. In cutting lens hole care must be taken that you are dead-centre with the centre of condenser.

It will be noticed that I have fixed two side and a top piece of wood to the lens board, and these are really necessary; they not only keep the front board steady, but completely cover in the bellows when the front is closed up, protecting it from injury.

The sliding baseboard should now be fixed, and consists of a board 16in. long by 8in. wide, attached to lens front at one end, the other part of which slides in the two grooved pieces that are fitted to the base of body.

When fixing up lens front, allow the bottom edge to project sufficient distance below sliding base for it to form a rest for the front on the table, or whatever the apparatus is stood on when in use, Fig. 7. The carrier must now be tackled, and is a very simple matter. Cut out a piece of soft wood 9½in. by 6¼in., and cut a hole in centre slightly smaller than a ¼-plate, as shown in Fig. 8, and on this tack pieces of thin wood—cigar-box wood, for instance—to make up to slightly thicker than your negative, and over all tack a similar piece of wood to the first piece described, leaving a slit in top only for the negative to drop in similar to an ordinary lantern carrier. This must now be planed down to the correct size, to enable it to slide easily between the two pieces of wood that are screwed to front of body.

The apparatus is now complete, with the exception of a board to stand the whole upon. It is as well to have this, and it will be seen from the illustration what I mean. It will be noticed that I have screwed on wood strips to act as guides both to the front and back, and find them very useful. It will also be noticed that I have fixed to one of these strips a little arrangement for keeping the front steady when moved out to the proper position, and this is also a very necessary arrangement to have.

* Extracted from an article by "A. T. H." in *Photographic News*.

GOLD IN SEA-WATER.

THE schemes for extracting gold from sea-water are apparently taking definite form; but the following account of an experiment made by a reporter of the *Daily Mail*, who went to Brighton and took some samples of sea-water, is interesting:—

"I could only experiment, obviously, with a very small amount of water, a few gallons—and I did not therefore expect to get a vast quantity of gold. My idea was to prospect for a trace of gold, and then to refer to the ocean itself those anxious for larger quantities of the metal.

"I had been privately apprised of the nature of the particular substance which was to do the main work in wresting the gold from the water; and I had myself purchased, at a tradesman's selected on the spur of the moment by myself, unknown to anybody else, a quantity of this substance. I am not allowed to mention just what it is, but it is a thing in daily use by many people, and is to be purchased in quantities for a few pence or a few shillings, according to the amount desired.

"Having obtained my few gallons of sea-water, I dropped therein the substance I had bought, which, I was assured, would precipitate to the bottom of the water a muddy residuum technically known as 'sludge,' which sludge would contain such gold as the water would contain.

"Of this substance, as I have since ascertained, I ought to have dropped about an ounce only into the quantity of water upon which I was operating. Through a misunderstanding, as I now learn, I placed just about forty times too much; and the result was the quantity of sludge precipitated was greatly in excess of that for which there was any need. In other words, I had, in securing the fixed quantity of gold in the water, made a great deal too much sludge in which that gold was hidden. I brought away with me three 40oz. jars full of sludge, whereas I am assured I should have brought exactly the same amount of gold—no more and no less—if by proper treatment I had only one 40oz. jar of sludge.

"My three jars of sludge I took to an assayer; and in selecting my assayer I purposely avoided, in order to secure greater independence for my test, the assayers who had formerly assayed the sludge taken to them by the patentees, in which they had found 0·150 grain of gold, equivalent to 9·729 milligrammes, from 50 gallons of water.

"Yesterday I received the following

Report from the Assayers

I had selected:—

"CERTIFICATE OF ASSAY.

"Assay Offices and Laboratory,
"6 and 7, Coleman-street, E.C.,
"Dec. 7, 1899

"FRED. CLAUDET, Assayer to the Bank of England.

"To the *Daily Mail*.

"I have examined the sample of sludge received on the 5th inst., and find the following to be the result:—

"GOLD.

	Milligram.	Grain.
Total contents of sample ..	0·2 ..	·0031

(Signed) "ARTHUR C. CLAUDETT."

"Here, then, are the simple facts of the test. What the patentees, or a syndicate to be formed by them, intend to do is to purchase or rent land near the seacoast, and run sea-water on to it at every tide. Precipitating the sludge at each tide, and then

letting the water out; they propose to continue until such time as it might be deemed advisable to have a clean up, when the sludge would be dug up, and the gold separated in the ordinary way.

"The patentees calculate that the 'pay-dirt' thus obtained would be rich enough to yield big dividends. Upon that point it is obviously too early to express an opinion. That it is an imaginative and picturesque scheme cannot be gainsaid; but the infinitesimal trace of gold revealed by this test does not seem to herald a day when a man may go into a bureau de change, plank down a bucket of sea-water, and receive a sovereign or two in exchange.

"Certainly much better assay reports have been yielded by former tests made by the patentees; but the desire of those patentees to permit a syndicate to share the marine gold with them suggests more benevolence than one often meets with nowadays."

STERILISATION OF WATER BY OZONE.

SINCE 1891, the sterilisation of water by means of ozone has been the subject of numerous investigations. M. J. Blondin, in an article in *Eclairage Electrique*, refers to some of the earlier of these, and then passes on to a description of the apparatus designed by Marmier and Abraham, and of the results obtained by them at Lille in 1898-99. The installation comprises an alternating current generator, a transformer giving 30,000 volts at the terminals of the secondary, a plate ozoniser, and an absorbing tower. The special form of ozoniser used has each of the metallic electrodes inclosed between two glass plates. The electrodes are kept cool by means of water. The absorbing tower is built of masonry.

Tables are given showing the chemical and bacterial character of the water before and after treatment with ozone. The ozonised air passed into the absorbing tower contained between 5·8m.gr. and 9·5m.gr. ozone per litre. The organic matter was reduced from ·014gr. per litre to ·003gr. per litre, and the bacteria in several instances were completely destroyed, while in other cases they were greatly reduced in number and activity. It was noticed that the results were best when the bacterial examination of the water did not immediately follow the treatment in the ozonising tower.

The report of the Commission appointed by the Municipal Council of Lille to examine the apparatus and process is given as a note to the article. This report is favourable to the method, and recommends the adoption of the Marmier and Abraham sterilising process at Lille, where the present water supply is contaminated, and typhoid fever is prevalent.

The author, in conclusion, discusses the question of cost, and expresses his regret that Marmier and Abraham have not supplied the necessary data to enable this to be accurately fixed.

Science Abstracts, from which the above is taken, also refers to Mr. Andreoli's paper on the same subject in the *Electrical Review*. After criticising the form of ozoniser used by Marmier and Abraham, he quotes several passages of this report, in which the efficiency of ozone as a germicide is proved.

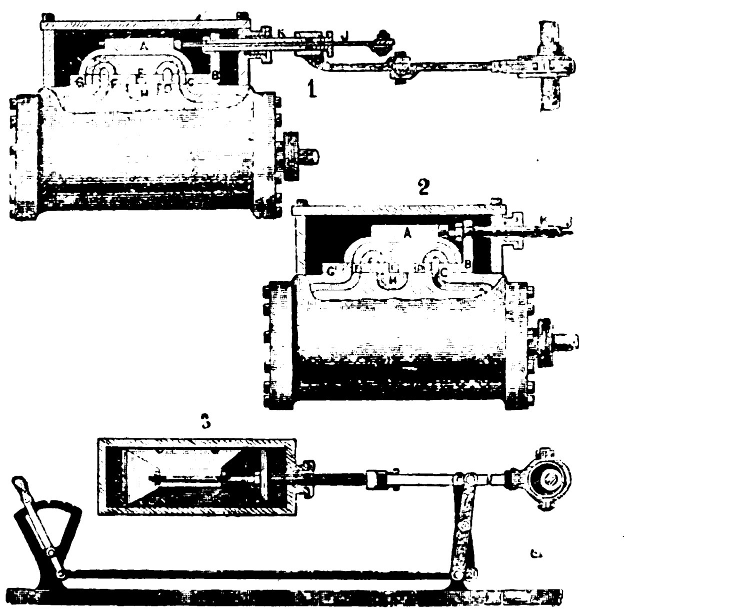
The author next discusses the question of cost, and states his opinion that the two centimes per cubic mètre, given by Marmier in an earlier paper, is too high. In order to throw further light upon this question, Andreoli has himself recently carried out experiments in London, and has measured the consumption of ozone in terms of electrical energy. The experimental plant consisted of a small Andreoli ozoniser worked at a tension of 3,500 volts, a Roots blower for forcing the ozonised air through the water, and five tanks in which the absorption of ozone by the water occurred. The plant permitted the treatment of 440 gallons of water per hour. A table is given showing the effects obtained, with expenditures of electrical energy varying from 138 to 316 watts per cubic mètre (220 gallons) of water.

The author concludes from his experiments upon Thames water that complete sterilisation of water drawn from the river at specially selected spots could be obtained with an expenditure of electrical energy equal to 100 watt-hours per cubic mètre of water.

M. Blondin, in his paper, refers to Andreoli's claim to have designed an ozoniser giving more economical results than the form used at Lille, but points out that, in the absence of more complete data, it is impossible to compare the results obtained by the two forms of ozoniser and systems of treatment.

DAMERELL'S SLIDE-VALVE FOR STEAM-ENGINES.

THE improved slide-valve which forms the subject of our engravings consists of two parts, a distributing-valve, A, and an independently movable section, B, interposed between the ports of the cylinder and the distributing-valve, A. The distributing-valve is independently adjusted by a stem J passing through a sleeve, K, connected with the slide-section, B, and with the eccentric. The sleeve K is offset in the form of an arm, while the stem J extends straight through the offset. Two independent connections are thus obtained for working the parts of the compound valve together or separately.



The distributing-valve is formed with a large exhaust-chamber opening inwardly in the middle and through ports near its ends, and with two induction-ports opening into the steam-chest, to admit steam through the passages, G, F, D, C, into the cylinder ports.

The distributing-valve rod, J, as shown in Fig. 3, representing a side view of the valve-shifting mechanism, is jointed to the upper end of a lever fulcrumed at its middle to an arm, and connected at its lower end with a rod pivoted to an adjusting lever; the upper end of the arm is connected with the eccentric rod.

When the ports are in the position shown in Fig. 1, steam enters through the proper induction opening, and passes through F and the port communicating therewith into the cylinder, forcing the piston to the right. The steam is expelled through the other cylinder port, through C, through the centre exhaust-chamber, through E, to exhaust H. When the rods are together moved to the right by the eccentric, the valve, A, B, shifts to the right, and the port G is over the left cylinder port, D is over the other cylinder port, and live steam passes through D to the cylinder port, forcing the piston to the left; the steam passes out through the left cylinder port, through G, to the central exhaust-chamber through E to the exhaust, H. To reverse the motion of the engine, the relation of the distributing-valve A and the slide-section B is changed by means of the rod J and sleeve K; for this purpose the distributing-valve is slid to the right on the section B, as shown in Fig. 2, by means of the shifting mechanism. As before, the parts, A and B, are reciprocated by the eccentric; but G and C are now changed to live ports, and D and F to exhaust ports, which changes the direction of the engine's motion. The valve is the invention of Henry Damerell, Ludlow, Mo.

FILTRATION MADE EASY.

"CLEANLINESS is next to godliness" is a time-honoured saying which photographers can well afford to bear in mind, for there is little doubt that there would be more of the latter commodity in the dark-room if there were more of the former. There is undoubtedly a great temptation to relieve one's feelings with a little Low Dutch when it is found that an otherwise perfect negative or faultless print has been disfigured, if not hopelessly spoilt, by a little dirt from this solution or a little sediment from that.

All of us, especially beginners and those of the use-it-over-again type, would get better results if we used the filter more often. Who has not been troubled with a black metallic deposit in the twice-used toning bath, and the inevitable specks of dust and straw which delight to fix themselves in our old friend, "Twopence-a-pound"?

It is the experience of the writer that a small piece of cotton-wool, so placed in the funnel as to enter the leg about ¼in., and extend a little way up the sides, is sufficient to remove most of the difficulties. It may not be perfect as a filter, but acts as a convenient screen, and is not intended for the use of the quantitative analyst.

The pad should be wetted a little, in order to drive out the air before pouring on the solution, the latter being done carefully, and not in fits and starts. Again, to screen the broken glass tube from the gold chloride solution with the same pad as has been used to filter a 10 per cent. solution of hypo, is hardly *bon ton photographique*.

We will now consider the best way of keeping the wool so that it is always handy when required. If the amount you expect to use is small, an empty plate-box comes in very well. A semicircular hole from ¾in. to 1¼in. diameter, is cut in one end of the lid, and the box filled with cotton-wool (that known as "medicated" wool being the purest obtainable). This is fed through the hole in the lid, and the requisite quantity torn off against the side of the box. The hole may either be left open or a cover formed by a piece of card, hinged on wide tape and glued to the side. Thumb-holes are cut in the lid to facilitate opening the box when refills are required.

A rather superior article with greater capacity may be made from an empty cocoa-tin. Even if it is "best and purest" the tin must be well cleaned and dried, after which a hole is cut in the centre of the lid, and the piece of tin left on to form a cover and a means of cutting the wool.

An additional feature of this box is a spiral spring, which carries a circular card, and thus keeps the wool up to the mark. The same end may be attained by suspending this card from pieces of elastic fixed to the sides near the top.—C. A. Colyer, in *Photographic News*.

A RIVAL TO CELLULOID.

NITRATED cellulose has long held the field as the basis of a flexible glass, as celluloid has been called; but there seems a probability that before long Messrs. Cross and Bevan's invention, aceto-cellulose, may be found a formidable rival, for it possesses many advantages over the pyroxyline which, in combination with camphor, is the main constituent of celluloid. We learn from a foreign journal that the manufacture of tetracetate of cellulose has, during the last few years, made rapid strides, as also has the butyrate, which is a somewhat analogous substance, the substances being now produced on a large scale.

Perhaps the most conspicuous quality of the acetate, compared with the nitrate, is its non-inflammability—it burns very imperfectly. It differs further from the latter in that it is insoluble in methylic and ethylic alcohols, acetates of amyl and ethyl, acetone and ether, but is soluble in benzoate of ethyl, chloroform, epichlorhydrine, acetic anhydride, glacial acetic acid, and nitro-benzine, the solution in the latter becoming a solid, completely transparent jelly. The solution in the other named liquids can be diluted with acetone without precipitation taking place. The aceto-cellulose resists most reagents in a remarkable manner. Dilute acids and alkaline lyes destroy nitro-cellulose; but, with the exception of dilute nitric acid, do not act act upon the new substance, in some cases even when boiling.

It is probable, too, that, used as a basis for films, it will be possible to dry them quickly by the aid of alcohol in the usual manner, a process quite out of question with celluloid, as anyone knows to his sorrow who has tried it. The acetate does not change by the action of heat below 300° Fah. The hydrate of cellulose possesses very similar properties, but is more soluble in the liquids named,

and is also easily soluble in acetone and in acetate of ethyl. The butyrate is very similar to the acetate, but the filaments formed from it are softer and more flexible. From all these facts the journal alluded to predicts that the new substances will be powerful rivals to celluloid, and especially in cases where non-inflammability is an important consideration. Finally, it is anticipated that they will form excellent lacquers for metal, their resistance to moisture, heat, and chemicals being far above that of the usual basis; of course, any colour can be given to them that may seem desirable.—*British Journal of Photography.*

ALTITUDES OF RAILWAYS ABOVE SEA-LEVEL.

WE propose in the following short article to give some interesting particulars of altitudes attained by the principal railways in different parts of the world. As it would be tedious to our readers to place these details before them in the body of the text, we shall give them in a tabular form, which will enable them to be the more readily compared and appreciated. It might be supposed that the rack railways would head the list, but though they run the others very closely it will be seen from

Table I.—Rack Railways.

Name of railway.	Maximum altitudes in feet above sea-level.
Pike's Peak, U.S.	13,200
Görner-Grat	10,065
Jungfrau	7,613
Rothorn	7,425
Pilate	6,850
Rigi	5,578
Monte Generoso	5,280
Gaisberg	4,243
Semmering	2,912

Table II. that they do not quite bear away the palm. There are three lines which may be referred to independently of those scheduled in the tables, as they are laid out partly on the rack and partly on the ordinary steam traction system. These comprise the lines between Beyrouth and Damas, and between Eisenery and Vordenberg. They are both in Syria, and attain each an altitude 3,960ft. above the same datum. The state railway from Herzegovina to Bosnia, belonging to the same system, reaches to a height of 2,904ft. above sea-level. It will be advisable to tabulate the other lines, which are ordinary locomotive railways, under two heads—viz., those which belong to Europe and those which are situated in foreign countries.

Table II.—European Railways.

Name of railway.	Maximum altitudes in feet above sea-level.
Land-quart to Davos	5,390
Kaltlad to Scheidegg	5,201
Brenner	4,494
Guadarrama, Spain	4,488
Mont Cenis	4,290
Lioran, France	3,800
St. Gothard	3,811
Alais to Brionde, France	3,395

It should be mentioned that the first two lines in Table II., are both located in Switzerland, and have a gauge of one mètre.

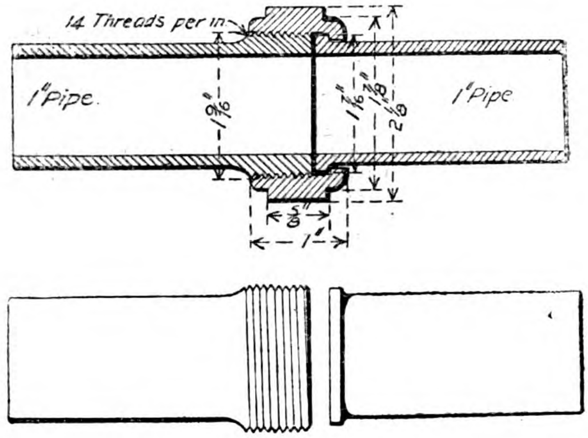
Table III.—Railways in Foreign Countries.

Name of railway.	Maximum altitudes in feet above sea-level.
Central Peruvian	14,555
Chilian and Bolivian	13,000
Danvers and Rio Grande	11,385
Vera Cruz	9,042
Union Pacific	8,292
Canadian Pacific	5,940
Northern Pacific	5,610

The highest altitude to which a cable line has attained is that of one near Stanserhorn, which rises to 6,100ft. It will be observed that with the exception of the Pike's Peak rack railway, the lines which traverse the passes of the Andes, in South America, can give the others a wide berth, although some of them can boast of very respectable figures.—*The Engineer.*

PIPE UNIONS MADE DIRECTLY ON THE END OF THE PIPE.

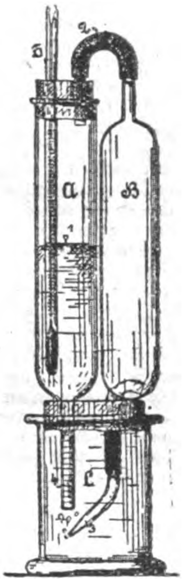
THE accompanying engraving illustrates a new pipe union devised by Mr. T. R. Browne, Master Mechanic of the Juniata shops of the Pennsylvania Railroad at Altoona. The first glance at the sketch shows the clear opening through the joint, which is entirely free from obstruction. This is not true of the ordinary commercial unions. These new unions are made by a very simple process on a bolt header, by use of a pair of dies. In each case the external die is formed to the shape of the finished piece. The internal die consists merely of a plunger of two diameters, the larger repre-



senting the larger diameter of the union and the smaller diameter corresponding with the inside diameter of the pipe. The dies are so made that before any upsetting takes place on the pipe the internal die has entered the external die in such a way as to form a closed or solid die. This method permits of the use of the next smaller size of standard union nut than would be used with the standard union. For example, for a 1in. union made in this way, a standard nut for a ¾in. union may be used. These unions are very simple and neat, and they possess the advantage of reducing the number of joints and opportunities for leakage, as well as making a very strong joint.—*American Engineer*, N.Y.

TESTING AMMONIA FOR USE IN REFRIGERATING MACHINES.

IT having been established that ammonia, whilst delivered with an initial impurity of 0·1 to 0·3 per cent., chiefly water and a little piridine, gathers impurities by frequent additions of fresh ammonia, as also through the machinery—as, for example, by



condensation of air moisture on the piston-rod, &c.—may ultimately be found to have accumulated impurities to amount to as much as 10 per cent. of the ammonia in circulation, according to experiments made by Dr. Lange, who has got this result in more cases than one, it is necessary in order to obviate the very injurious effects of such impurities on the working efficiency of cooling machinery to take periodical tests of the fluid, as may be done by evaporating a fixed quantity of the ammonia to be tested in a measured glass, the contents (i.e., impurities) left behind being easily calculated.

C. Richter's method is to take a glass tube, A (see illustration), with its lower end (4) elongated, reduced, closed, and marked off in distances equal to 0 2 per cent. each. Fill with the ammonia to be tested up to mark 1. Plug the top, and lead with rubber tube, 2, into glass tube, B, which, with open tube, 3, at bottom, admits the evaporated ammonia into the glass cylinder, C, the water contents of which absorb the escaping ammonia, whose combination with the water generates sufficient heat to completely evaporate all ammonia in tube A. What remains in tube 4 is an impure fluid, whose percentage to the total can be read in the tube itself. This should never exceed 1 per cent. If this point is exceeded, the ammonia must be thoroughly rectified. Indeed, all ammonia should be tested on delivery, and if found to contain over 0·5 per cent. of foreign stuff, it is not so pure as may fairly be claimed by the buyer.—*Cold Storage.*

USEFUL AND SCIENTIFIC NOTES.

In Chicago there are 956 miles of "surface railways" or tramways, and 70 miles of elevated railways.

A system of electrical driving and lighting has been adopted in the new shops of the Thames Ironworks and Engineering Company at Blackwall. This company has in hand orders from the Admiralty for ten sets of machinery for 56ft. vedette boats, nine sets of machinery for 40ft. steam pinnaces, and six sets of water-tube boilers for 40ft. pinnaces. In addition to these the Admiralty have given them the order for a third set of battleship machinery of 18,000I.H.P.

The Coming of Man.—Prof. Grenville Cole has a fascinating article on this subject in the current number of *Knowledge.* He says:—"The remains of man are notably subject to decay, and the signs of his former existence in this or that locality often depend upon the more enduring objects that his skill has left behind. Baked pottery, chipped stone implements, the very charcoal of his fires, may survive in places where his own bones are extremely rare. Much of our knowledge of early man is derived from interments conducted with careful ritual by his tribal fellows. Is it likely that, in a ruder age, when ceremonial burial may have been utterly unknown, the skeleton of man would have much chance of preservation? . . . . Unlike many other mammals, early man was not compelled to collect in vast herds around the lakes and water-courses. His very intelligence, his variety of aim, made him a wanderer across the earth. Dying in the forest, or on the barren rock, or isolated in his log-canoe, his skeleton was rarely covered over and adequately preserved. He was small in comparison with the giant carnivores, with which he competed for his food. Even if he died a natural death, the very fowls of the air could combine to scatter his remains. . . . Hence, as we work backward, from the present deposits to those of earlier days, the number of human skeletons discoverable decreases with extreme rapidity. Yet there are, up to a certain point, abundant evidences of the occupation of the earth by man. The conclusion is that the earliest types of humanity, without arts, and perhaps without tribal organisation, have probably left very few traces through the strata of the entire crust. . . . . Man presents himself to the calm and inquiring eye of science in so many aspects, in so many fields of enterprise, that it is difficult to deal comprehensively with his career upon the earth, as we might with that of the cockle or crayfish. He is so near us, even in the Malay or the Negro, that we are apt to place him in a category apart from the rest of animated nature. Even the young science of anthropology, by its very title, confesses that zoology cannot cope unaided with the details daily provided by the aberrant activity of mankind. . . . Have we already advanced since Zittel wrote, in 1895, 'The problem, where man first appeared on the earth and from what form he sprang, has, in spite of all efforts of modern geology and anthropology, up till now found no solution'? If we have indeed advanced, along the lines indicated by the discovery of Dubois, it is but as yet a single step, founded upon a single skeleton. To some thinkers, however, this single step provides a field of vision surpassing all that went before; to others, the coming of man remains, to this day, one of the profoundest secrets of the crust."

SCIENTIFIC NEWS.

SOME time ago it was proposed to have at Harvard College Observatory a telescope of unusually long focus for photographing the stars and planets. It is now announced that the funds have been provided by anonymous donors, and that before many weeks have passed a telescope with 12in. of aperture, and rather more than 100ft. long, will be ready for work.

The *Bulletin* of the Société Astronomique de France for December contains an interesting article by MM. F. Quénisset and Em. Touchet on "La Lumière Cendrée de la Lune," illustrated with reproductions of photographs taken at various times and places. M. Camille Flammarion has quite a valuable article entitled "En quelle Année commencera le Vingtième Siècle?" in which he quotes several passages which may help to explain how the idea got about that the 19th century ended with 1899. He says "Le vingtième siècle commencera donc le 1er janvier 1901," and he gives a map showing "le ligne géographique du changement de date quotidienne."

It is stated that Mr. Coddington, of the Lick Observatory, discovered a new minor planet by means of a photograph taken with the Croker telescope, and afterwards obtained a series of observations during October and November from which he was able to determine an orbit.

Mr. Horace Darwin suggests that the striking colours of recent sunsets are possibly due to the dust in the air from the Leonid meteors. It has been shown that even in mid-Atlantic the air is always full of dust—cosmic dust it has been called—and if that shows itself or is detected in abnormal quantities it may very well be urged that it comes from the meteoric stream.

In the course of some remarks introductory to a series of lectures by Mr. William Peck, astronomer to the City of Edinburgh, Lord Provost Mitchell Thomson said it was very gratifying to know that the City Observatory had been largely taken advantage of by the public since it was thrown open to them. Certain nights of the week were set apart for visitors, and already thousands had taken advantage of the arrangements for seeing the observatory and of obtaining some definite instruction in astronomy and astronomical methods. Among the visitors were several gentlemen eminent in that particular science, who had expressed astonishment and admiration at the fact that Edinburgh possessed so fine an observatory. Classes for the teaching of theoretical and practical astronomy had been established at the institution, and arrangements were nearly completed for the holding of classes for pupils from the secondary schools, who would receive instruction in a science which, as Mr. Peck would show the audience that night, was associated in so practical a way with the everyday life of the people. Mr. Peck's lecture was on "Time," and in the opening he dealt with the various methods of time measurement, and explained how time was determined by observations of the heavenly bodies, the star sphere being to the astronomer as a perfect clock. In the second part of the lecture Mr. Peck described the various time cycles in use, as the sidereal day, the true solar day, and the mean solar day. Then he dealt with the week, the sidereal and synodic months, as well as the sidereal, tropical, and lunar years, and the perfecting of the calendar under Julius Cæsar in 45 B.C., and Pope Gregory in 1582 A.D.

The 200th anniversary of the Königliche Preussische Akademie der Wissenschaften of Berlin will be celebrated about Easter next by a special celebration, to which foreign delegates will be invited.

An international congress of mining and metallurgy will be held in Paris next June (18-23). It will be under the direct patronage of the French Government. M. Gruner, Rue de Chateaudun 35, Paris, is the general secretary, and will give all particulars.

It is announced that a course of twelve demonstrations in experimental psychology will be given in the Psychological Laboratory of University College, Gower-street, during the Lent Term, by Mr. W. McDougall, Fellow of St. John's College, Cambridge. The class will meet once a week on the day and at the hour that are found to be most convenient to the majority of the students. The methods of investigating experimentally all the chief types of elementary mental process will be demonstrated, and the students will be afforded opportunities to practise the methods. The subjects of investigation will include skin-sensibility and the muscular sense; the colour sense and visual distance; appreciation of tone-intervals and localisation of sound; the measurement of sensibility to pain; simple measurements of memory; estimation of periods of time, &c. Students should send in their names to Mr. McDougall, St. John's College, Cambridge, before Tuesday, Jan. 16, 1900, when the term begins, and should be present at the first meeting on Friday, Jan. 19, at 4.30.

At the Society of Arts on Wednesday, Dec. 20, Mr. H. Bloomfield Bare, F.R.I.B.A., will read a paper on "Bi-Manual Training by Blackboard Drawing."

At the meeting of the Royal Geographical Society on Monday last, Mr. H. Weld Blundell read a paper describing a journey through Abyssinia, in the course of which he said that from Bilo was a march of two and a half days over an extraordinarily rich country, hilly, but well watered. The country along the road showed the destruction wrought by passing expeditions, though probably this cause had not been so pauperising as the appalling loss of cattle through rinderpest, which had in many places almost annihilated the principal wealth of the inhabitants from Harar through the whole breadth of the country. Cotton seemed to grow luxuriantly, as well as tobacco. The great grass fires disfigured the landscape with patches of blackened desolation in early spring, but the verdure that sprang up with rapid luxuriance showed the value of this primitive expedient by which the natives clear the ground for grass and cultivation. The younger growth of trees got killed off, but the great monarchs of the forest that had held out against the conflagrations stood out here and there in the landscape, and looked worthy of being invested with the religious reverence of the Salla race. The party reached the town of Gatama, immediately below which could be seen the valley of the Didesa, with dense forests and hot jungle. Lekemti was described as a large scattered town of some 40,000 inhabitants, situated on undulating ground, with all the evidence of prosperity, corn and honey being the principal produce, and there being also large quantities of cotton, native and American; iron and copper from the west, too, were to be seen in the markets. Arrived at the frontier, Mr. Blundell learned that the Blue Nile was at no great distance, and in barely five and a half hours' marching found the valley of the Abai at his feet, and the silver sheet of water not six miles off. According to the maps, this point of the Abai would be nearly 70 miles from the camp at Mendi; and he thought the explanation of the error lay in attributing this stretch of the river to the lower reach of the Didesa, which, however, could be traced from this point of view joining the Nile at the range called the Chochi, some 20 miles further south than its junction as placed in the maps. On May 6 they crossed the Blue Nile and joined hands with the commandant of Famaka and his detachment of 10th Soudanese, which had distinguished itself at the desperate fight with Ahmed Fedil, near Rosaires.

In the course of a lecture before the Royal Courts of Justice Temperance Society on the "Physiological Aspect of the Temperance Question," Mr. Victor Horsley said that though he was a rabid teetotaler he had often heard statements on temperance platforms as to the effects of alcohol which he could not endorse. But quite recently it had been definitely ascertained that even in small doses the effect of alcohol was physiologically maleficent. Alcohol injuriously affected the nervous system, diminished the oxidation which was necessary to the protoplasm of the brain, and produced a certain amount of degeneration of the tissues even in healthy persons. As to the use of alcohol in disease, about 50 years ago every patient undergoing an operation or suffering from pneumonia or typhoid fever was largely treated with alcohol. But nowadays the practice of any general hospital was very different. The expenditure on alcohol had been largely replaced by expenditure on milk. In surgery this reform was largely due to the antiseptic system introduced by Lord Lister. The dosing of a patient with alcohol before an operation and during the recovery from it was now no longer necessary; and in this connection the enormous amount of pain as well as of life which had been saved by Lord Lister's system should be remembered. As to the remedy for intemperance, he thought it most important to establish the principle that the moral responsibility for drunkenness rested primarily on the man who sold rather than the man who bought the drink. In answer to a question, Mr. Horsley said that, in cases of faintness, alcohol was often the worst treatment that could be administered.

An interesting paper on injurious insects in Indian forests has been prepared by Mr. E. F. Stebbing, and published by the Government printer at Calcutta. Amongst the most destructive pests in the insect world infesting the forests of India are locusts and white ants, or termites, the former of which invades the fertile plains of India from its home in the sandy deserts of Rajputana, Sind, and the Punjab, leaving not a green leaf or field in the line taken by it. As the life-history of the locust proves that forests and moisture are its greatest enemies, the reclamation of arid sandy areas by means of plantations is recommended as a means of checking its multiplication. Although the white ant is a most unwelcome intruder in any building, it renders service to man in the forest by rapidly converting dead branches, fallen trees, and decaying wood of all kinds into soil, each particle of wood eaten being replaced by humus. Where termites are numerous, they only feed on the outer dead portions of the bark of trees, and do no damage to healthy trees. The instinct of these insects, Mr. Stebbing says, is marvellous. He has often noticed that should a tree have a dead branch on its trunk, no matter at what elevation, an earthen gallery is run up by white ants and the branch attacked, the decaying wood being replaced by soil, which soon falls to the ground.

According to M. Lanfrey, in a communication to the Paris Academy of Sciences, a one per cent. aqueous solution of picric acid applied during June—August is useful in destroying the Phylloxera. It is also useful as a syringe-drench for other fruit trees. Amongst dyers, picric acid has been well known for years; there is a suspicion that it is used by brewers, and it is quite certain that it forms, when properly treated, a very powerful explosive.

"A curiosity in the shape of a pied woodcock has been shot near Blofield, in Norfolk. The bird was an unusually fine one, weighing 12oz., and had the white feathers evenly distributed in both wings. One of the leading ornithologists of the day, to whom it has been submitted for examination, observes that he has never seen a woodcock marked as the one in question." The name of the leading ornithologist is not mentioned in the paragraph quoted.

Some years ago the late Prof. Huxley made a report about the herring fishery, and stated that there was no reason to suppose that the somewhat alarmist rumours as to the number of fish decreasing were based on facts. In this connection it is worth mention that, so far as Yarmouth is concerned, the past season is the record—the value of the fish captured amounting to over £300,000. One boat alone has £3,000 to its credit, and the amount paid to the cleaners and salters was £13,000. Many of the cleaners come from Scotland, and they had a special train to take them home.

The death is announced of the distinguished pathologist, Dr. Birch-Hirschfeld, professor of pathology in the University of Leipzig. He was only fifty-seven.

It is notable of the progress of bacteriological science that a patent has been obtained in America for a sanitary attachment to telephone transmitters, by Mr. W. Lenderoth, of Manhattan, New York. It is described as a wire frame, having a ring and bent arms to clamp it on the front of an ordinary conical transmitter. Three wires project forward from the ring forming a cage, in which is inserted a temporary paper cone, which may be removed and destroyed after the telephone has been used.

It is stated that heavy cannonading does not interfere with the transmission of signals by Marconi's system of transmitting by "wireless" telegraphy. A "school" for training operators has been established on one of the hulks in Portsmouth harbour.

There is a probability that electric traction on the Metropolitan Railway will be adopted soon, as the experiments which have been made have

proved quite satisfactory. The "motors" are nearly 40ft. in length, and will draw long corridor coaches similar to those on the City and Waterloo line.

Before long the telephone will be established between Vienna and Constantinople. The Hungarian and Servian Governments have arranged for a telephone wire between Budapest and Belgrade, which is expected to be working at the end of January. From Belgrade the Servian Government has granted two more telephone wires, one to Sophia and another viâ Uskub to Constantinople. There is a telephone already working between Budapest, Vienna, and Berlin. It may be expected that the German capital will soon have telephonic communication with Constantinople.

Aluminium is being extensively used for the manufacture of cooking utensils in India. The metal has also been used for the bearings of shafting at the Madras College of Engineering, and is said to have proved satisfactory.

At a meeting of the Royal Irish Academy, Mr. Trouton showed an apparatus with which he had determined the heat required for evaporating steam from saline solutions. The subject is of considerable importance, as it would be of immense advantage if sea-water could be readily converted into steam without too much "refuse" being left behind.

A chair of geology at McGill University, Montreal, has been founded by Sir W. C. Macdonald as a memorial of the late Sir William Dawson. The income of the endowment is to be paid to Lady Dawson during her life, and afterwards will become available for the maintenance of the chair.

THE Compagnie Générale de Traction, which owns sixty miles of line in Paris, will eventually equip the whole of it on the Diatto electrical traction system.

Human Teeth an Index of Race.—"The size of the jaws will be largely determined by the size of the teeth," says Prof. Arthur Thomson, in the December issue of *Knowledge*, "and as in savage races the teeth are, as a rule, larger than in the more highly-civilised peoples, it naturally follows that the architecture of the face will be modified by the massiveness of the jaws and their associated structures. The late Prof. Sir William Flower was amongst the first to recognise this fact, and by comparing the length occupied by the upper molars and premolar teeth with the length of the cranio-facial axis (basi-nasal length) he determined the dental index by the following formula:—

$$\frac{\text{Length of 5 molars} \times 100}{\text{Basi-nasal length}} = \text{Dental index.}$$

In this way he was able to group the races of man according to the size of their teeth into three varieties:—(1) The Microdont, with an index below 42, including mixed Europeans, ancient Egyptians, low-caste natives of India, and Polynesians. (2) Mesodont, with an index ranging between 42 and 44, comprising Chinese, American Indians, Malays, &c. (3) Megadont, having an index over 44. This group embraces Melanesians, Andamanese, and the Australian and Tasmanian races. The reduction in the size of the teeth in the higher races is probably explained by a reference to the more common methods of preparing the food by cooking, &c., which renders unnecessary a powerful masticatory apparatus. On the other hand, the size of the teeth in the lower races is oftentimes much larger than might be at first assumed from a casual inspection of a large number of skulls. This fact was borne out during the discussion which took place on the remarkable fossil remains brought from Java by Dr. Dubois. These included a skull, a thigh-bone, and two molar teeth, presumably all belonging to the same individual. We are not at present concerned with the skull or thigh-bone, which the discoverer claimed, with much show of truth, belonged to an intermediate form between man and the higher apes, which he distinguished under the name of *Pithecanthropus erectus*, but rather to draw attention to the aspects of the case as determined by the teeth. These were of large size, and, among other points, it was urged that they were too big to be human. This assertion at once put all the anatomists who had large collections under their charge on the *qui vive*, and many hundreds of specimens were examined with the object of determining this point. It soon became apparent that this argument against the Trinil teeth being human would have to be abandoned, as a number of instances were forthcoming in which undoubtedly human teeth equalled, if they did not excel, the fossil specimens in size. It would therefore appear extremely hazardous to express any opinion as to the limits of size within which we should regard teeth as human."

LETTERS TO THE EDITOR.

[*We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.*]

All communications should be addressed to the EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

*** *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks; a vice from whence great inconveniences derive their original."—*Montaigne's Essays.*

THE LATE REV. G. F. CARRUTHERS—THE "ENGLISH MECHANIC" AND A SCOTTISH WORKING MAN—ALPHA ORIONIS AND RIGEL—ADJUSTING A TELESCOPE—REFLECTING STEREOSCOPE—THE HEAD MASTER AND THE USSHER — CALCULATION OF SUN'S TRUE BEARING AND ALTITUDE—GRAVITATION—EROS.

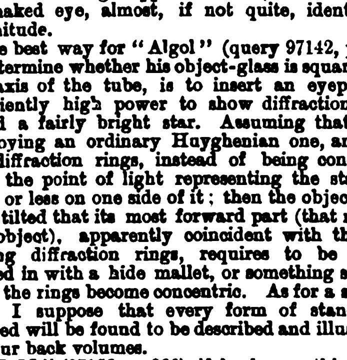
[43106.]—BY the death of the Rev. G. T. Carruthers, a quondam Chaplain in the Bengal Presidency, yet another paradoxer disappears from the columns of the ENGLISH MECHANIC for ever. His letters in these columns on numerical relations in our System, vapour in space, the cause of gravity—and a great deal more *ejusdem generis*, must be well within the recollection of many who will read these lines. In private life he was a most blameless and estimable elderly gentleman.

Mr. Smith (letter 43079, p. 361) is thoroughly right in his belief that I should be pleased to learn how successfully Mr. Glass had mounted his reflector equatorially from any sketch or directions given by me. I could hardly receive a more acceptable reward for the pains I took to make the subject intelligible than that derived from the knowledge that my unpretending efforts have enabled a genuine working man to construct such an instrument as that figured on p. 360.

Referring to reply 97060 (p. 364), it happened curiously that on the night of November 29, α Orionis and Rigel appeared to me, as viewed with the naked eye, almost, if not quite, identical in magnitude.

The best way for "Algol" (query 97142, p. 366) to determine whether his object-glass is square with the axis of the tube, is to insert an eyepiece of sufficiently high power to show diffraction rings round a fairly bright star. Assuming that he is employing an ordinary Huyghenian one, and that the diffraction rings, instead of being concentric with the point of light representing the star, are more or less on one side of it; then the object-glass is so tilted that its most forward part (that nearest the object), apparently coincident with the projecting diffraction rings, requires to be gently tapped in with a hide mallet, or something similar, until the rings become concentric. As for a stand—well, I suppose that every form of stand ever devised will be found to be described and illustrated in your back volumes.

"F. M." (97156, p. 366), if he be anything of a mechanic, can easily make a reflecting stereoscope for himself. I did so myself years ago. A plan may help him. In the sketch, B represents a large



flat board, on which are mounted two mirrors, M, M', forming an angle of 90° with each other. These face (obviously at an angle of 45°) the vertical slabs of wood P, P', upon which, by the aid of grooves, slides, or any other simple device, the photographs are placed. I have represented the course of the rays of light in my diagram by dotted lines; so, taking the left-hand photograph, it will be seen that the light from the picture will travel by the route P *r*, *m*, *r* E to the observer's left eye at E, while it will reach his right eye E' by the route P' *r' m' r'*. The size of the mirrors, board, &c., will obviously depend upon that of the photographs to be employed.

Put shortly, letter 43092, on p. 381, comes to this, "Ussher was a painstaking and learned chronologist"—when he happened to agree with Mr. Garbett,—whose identity is veiled under the euphemism, "the genuine Bible, and all other good chronology." Otherwise, like that poor creature and most incompetent mathematician Le Verrier, he is to be brushed aside as unworthy of any attention. I protest against this sort of argument (if it be not a gross solecism to dignify it by that name). For myself, I believe that Ussher is just as much—or as little—trustworthy as a chronologist, as any one of that brotherhood, not even excluding the infallible and omniscient Mr. Garbett himself. This being so, I find that he places the date of the Flood at 2,349 B C. But there is actually extant a Chinese Observation of the Conjunction of Mars, Jupiter, Saturn, and Mercury in the Constellation "Shi" (i.e., between 10° and 18° of Pisces), and this occurred on February 18, 2,446 B C., or 97 years before the mythical Deluge; whence it is abundantly evident that while Mr. Garbett's Steam Comet was flooding Armenia, China was left high and dry, and the Celestials were going about their daily avocations as usual.

Perhaps I may be forgiven for referring "Fleur-de-Lys" (query 97187, p. 387) to pp. 173, 241, and 242 of Vol. LVI., of the "E. M." as containing practical replies to his questions.

"Newton" (query 97217, p. 388) apparently forgets that the earth is surrounded by the atmosphere. In a very familiar lecture experiment a tall receiver is exhausted of air and a sovereign and a feather dropped simultaneously from the top of it, which both reach the brass plate at the bottom at the same instant. If, however, the feather and the sovereign are together let go from a height in the air of the room, the coin will fall on the floor very notably the sooner of the two. The balloon to which "Newton" refers must have collapsed and come down "all of a heap," while the resistance of the air to the lighter sand must have retarded its progress.

I think that "Garsdale" (query 97222, p. 388) will find that Herr Osten's value for the eccentricity of the orbit of Eros is 0·222911.

A Fellow of the Royal Astronomical Society.

THE SUNSPOT CYCLE.

[43107.]—WHEN I asked if it was not premature to assume that we have reached the turning-point of the sunspot curve, I had in view the ordinary smooth curve, in which the degree of solar spottedness in each year is expressed by means of an average number. I suppose it would be hardly correct to assign such a number for the present year till the year is complete, and that we cannot properly say whether 1899 is a minimum year (in the sense indicated) till the character of next year, at least, is ascertained.

Alex. B. MacDowall.

THE MOON AND THE WEATHER.

[43108.]—ONE meets with many dogmatic statements in meteorology, and the truth of these is generally not so apparent as the dogmatism. In the "E. M." this week, we find trotted out once more the view that the moon has nothing to do with the weather, because weather is local. Now there has been published this year a "Traité Elémentaire de Météorologie," by Prof. Angot, an admirable work by a recognised authority, and one which all who want to know the best thought in meteorology up to the present would do well to "read, mark, learn, and inwardly digest." He indicates some new and more scientific directions which the study of the moon in relation to weather has recently taken. Thus the position of the moon in declination is considered not in relation to a particular meteorological phenomenon (temperature, rain, change of weather, &c.), but to the general distribution of pressure on the surface of the globe.

"The fundamental idea of these researches," says the Professor (p. 399), "is that the movements of the moon in declination may cause general displacements of the air, an oscillation (balancement) between tropical regions and higher latitudes, and thus change periodically, e.g., the limit of the trade winds and the law of variation of pressure within the latitude. We can thus understand how the movement of a zone of high pressures, e.g., may bring good weather on one side of the zone, and at the same time bad weather on the other side, and how these variations, contrary at first sight, might nevertheless be due to the same cause. These studies are still too recent and too little developed to have already given results which may be considered sufficiently conclusive and general. It was interesting, however, to refer to them here, for it is by following this course that we shall perhaps succeed in discovering real relations between the movements of the moon and meteorological phenomena, where the older researches have not reached any serious conclusion. *En résumé*, in the present state

of our knowledge it cannot be affirmed that the moon has an influence on weather; but as little can it be denied that such influence may exist. In any case, it might be manifested by complex phenomena, such as the displacement of zones of high and low pressures, and might thus produce immediate results very different in different regions."

I should be glad to know what "S. R." and "F.R.A.S." have to say on this view of the matter, and whether they do not admit Prof. Angot's argument? A. B. M.

THE MOON AND THE WEATHER.

[43109.]—Although I am more than doubtful as to the influence of the moon on the weather, such an argument as that of "S. R." (p. 382) does not appeal to me at all. I take it that those who believe in lunar weather influence do it on the assumption that a tide is produced in the atmosphere. If so, "S. R.'s" objection to an aërial tide—viz., that the weather in London is not momentarily identical with that in other quarters of the globe—either proves nothing, or it proves too much, and would equally well show that ocean tides were not due to the moon. Glatton.

THE "LITTLEMORE" METEOR.

[43110.]—I was pleased to find from your report on p. 378 last issue, that this meteor had attracted special attention. As far as I was concerned it was almost the only reward of three mornings of watching. The meteor burst midway between Castor and Capella, leaving a brilliant stream in its rear of, perhaps, more than 5° in length; time, 5.40 a.m. on the 15th. The direction of the tail was at first N.W., but after some two minutes' observation I was convinced that it was slowly assuming a position differing from its original line of flight, and after about four minutes, when it was still visible, its direction was decidedly N.E. I hope others also noticed this peculiarity.

Northants. Frank H. Wright.

NEWTONIAN—GREGORIAN.

[43111.]—Since I wrote my last letter, I have been busily comparing the performance of my telescope as a Gregorian and a Newtonian, and think some account may be interesting to many readers, even if it bring down on me again the animosity "H." exhibited in his comments on my previous recital.

Testing upon ζ Boötis and η Coronæ as close doubles, both are completely divided with 400, ζ Boötis being rather the closer. There is no advantage in the one form over the other, the G. and N. are equal in results. The angles were estimated at 290° and 340°, and the observations made in August last.

For light test we selected μ Andromeda, and here the comparison was more easily seen in the N., being visible with 1in. less aperture than in the G.; while 4½in. in the one case does it, the other requires 5½in.

For flatness of field, the cluster in Perseus was observed. There the G. had undoubtedly the flattest field. The only planet available has been Neptune. There we got a sharper disc with the N., and only the N. would show the satellite, which was still a faint object. On the moon there is little to choose, but the G. has the flatter field. The N. exhibits all six in θ Orionis; but until now the G. has only shown four, although the small concave is now of solid silver. My optical friend who made it tells me he tests in the same manner as the large concave, but uses a microscope to examine the image.

Can any reader tell me anything of John Birch as an astronomer? I have read that an account of him appeared in an old *Leisure Hour*; but a search of some hours in old volumes has been fruitless, and I am inclined to think the story imaginary.

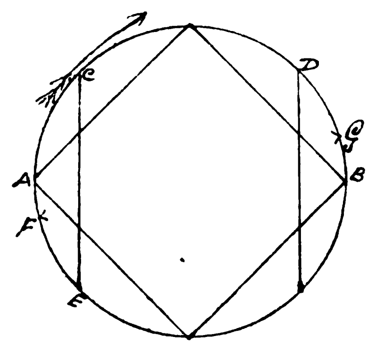
Eli Hay.

INTERNAL COMBUSTION MOTORS.

[43112.]—I have hitherto had nothing to say respecting the above, because I have had no experience with them, and these things are getting very numerous now; the while, from a series of accidents, I have been compulsorily idle. I have attended and witnessed some experiments with a gas-engine. I have stated some years ago that an engine driven by gas could be made very simple; there was no necessity for one half the work usually put on them. I first became acquainted with a gas-engine between 30 and 40 years ago; it was a Lenoir, and it was dismantled; I might say upon a scrap heap. My attention was called to it by an old shopmate. I heard tell and read about them, but had never seen one. When my eye rested upon the cylinder, I asked whatever that thing was for? The cylinder was 2in. thick, 4in. bore, and about 2ft. 6in. long, as near as I can recollect, and the stroke 16in. "Why," said I, "what a preposterous thing!" "What?" he asked. "Why, to make a cylinder like that." The answer was, "My dear boy, you evidently know nothing about it, I can see. You see, the explosive force of gas is so enormous that things are bound to be very strong." "How about a cannon?" "Oh, a cannon is nothing to compare with this." Well, I gave him my theory relative to the action of these things. Well, I said, the explosion is something, but there is no continuous expansive force, and there is no necessity for its being so cumbersome: it is a waste of material without adding to its strength. The action of the gas exploding is only momentarily; a reaction takes place—even the while the explosion is going on a vacuum or partial vacuum, and it is a kicking and sniffing engine to work properly. Well, I never had an opportunity of this until recently; the engine is made on the lines I set down, and very simple, with this exception—there is no turning-valve for the ignition. I maintain that ignition did not ought to be left to chance; that there should be four valves—ignition, exhaust, air, and gas—all independent, and all positive action.

Now in taking in the charge, you cannot get a full charge owing to the heated state of the cylinder; but instead of very near 15lb. as atmospheric pressure, it would be about 12lb., independently of the gases left in the cylinder. Now, when ignition has taken place, an explosion follows—i.e., if the gas and air are in due proportions. What is the result of explosion of the gassed water in the state of miniature globules?—and it takes time to convert that into vapour; and when converted into vapour, there is no mortal power that can expand it to make it occupy the same space that it does before with any pressure. This I have proved by this engine; it is 3⅜in. bore, 5in. stroke, and will run 700 revolutions per minute. It has given out a good half-horse. Now the valves have been adjusted by the springs in various ways, and the best result is when she is allowed to breathe—i.e., sniff, and that she does pretty stiffly immediately after the explosions.

I have given a diagram here for setting the cams, and the cams, as a rule, are not made to open sharp enough: it must be prompt action at the desired points. The points for exhausting seem in a fog. There are several engines—gas, oil, &c.—in my neighbourhood, and they cannot all be right. There is one sounds like a rifle, another like a pistol-shot; another goes with a blob, and another with a cackle; another three shots and a crash, and one three shots and a rest. There is one in a front shop—a large one—that, if you did not see it, you would not know it was there; the while one emits clouds of black smoke and soot, and another exhausts very mildly, with a "sush" and steam. Now these cannot be all right, and I am going to give you my points for the various purposes in the diagram. Let A B represent the stroke. Now, in working, it is very evident that the stroke travels



five times as fast from C to D as it does from E to C. Do not let your ignition take place before C. Your exhaust opens at D and closes at A; gas opens at F; air opens at A; gas and air close at G; then compression takes place with ignition again. There is nothing gained by expansion. By keeping D closed the springs of gas and exhaust and time valve should be strongest, and the air-valve hung as light as possible that it may snift its fill. I have never seen these lines given in print before, and they are very necessary. This does not only relate to gas-engines, but all engines driven by internal combustion and hydro-carbons. The points are four valves positive action each; the air-valve allowed its own sweet will. Early and complete exhaust water in a fine hot spray at the moment of explosion may prove a help; but I do not think there is any certainty of its action, and therefore prove more plague than profit, and the more simple the engine the better.

Jack of All Trades.

SPLICING.

[43113.]—"J. H.," the author of the articles on "Millwright's Work," informs us in one of his works "that fitting is one branch of that extensive practice of engineering to which the whole of his life has been devoted." Hence, as a practical fitter, he will know the importance of "erectors," having a thorough knowledge of the best "practice" in rope-splicing, hemp, cotton, and wire, and I hope he will not slip through his articles on "Millwright's Work" (as I am afraid he is going to do) without treating the matter in as an exhaustive a manner as he has done the jointing of belts.

I am constrained to write you on the above matter from the fact that I know two ways to make an eye-splice and short-splice. I also know two ways of "tucking" strand-ends in long-splicing. I have heard there is a third. Then there is the question what length to allow for splice, some allowing three and four times as much as others.

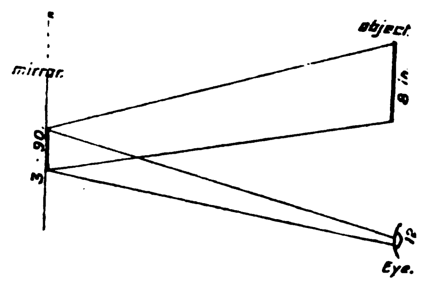
Now, there are many in the same boat as myself whose practice is not extensive enough to ascertain for themselves which is the best "practice," and when we turn to our textbooks they only bewilder us, as witness page 374, fifth series, "Spon's Workshop Receipts" "about 84ft. of rope is required to put in a good smooth long-splice." This refers to a wire rope. Now, would not a quarter of this length make just as good a job, say, in an inch rope? "J. H.," in his "Principles of Fitting," writing on the splicing of cotton ropes, says, "the splice is carried over a length of 4ft. or 5ft." Then in Article XIX., "Millwright's Work," he says not *less* than 6ft. to 12ft. Then he gives below a firm's table which runs from 9ft. to 20ft.

Will "J. H." give us the benefit of his experience, with diagrams, of the splicing tools in use, and I am sure he will earn the thanks of "ours" who, like myself, cried "hang it," when they opened the issue of Nov. 24?

Grenside, near Sheffield. Richard Hudson.

WHERE IS THE IMAGE FORMED?

[43114.]—Mr. Naylor (96871, p. 342) may be assured that I read his reply, and I do not see anything in his reply to induce me to withdraw aught that I have written; but, seeing the marks of the book strong in his reply, I elected to go for the textbooks instead of noticing the reply.



To his second communication I am induced to offer some remarks. In No. 1809 of the "E. M." he gives a diagram which is scarcely correct, inasmuch as that, in dealing with the reflection of an object from a plane mirror, we are dealing with converging rays, not with diverging, and actual measurement will make this plain. Given the observer and object at equal distance from a reflector, the object being 8in. in height, rays from it will converge towards the reflector, and have a measurement of a little less than 4in. Theoretically, supposing the pupil to be ·12in., it should be 3·90in.; the reflected rays converge towards a vanishing point, and enter the pupil before reaching that point.

Is Mr. Naylor in earnest when he asks "what angle?" If he will look to his diagram he will see that his imaginary point with dotted line forms an angle with a line in the plane of his object point, which line is frequently produced in similar diagrams. His imaginary point is simply a mirror ghost, and is an encumbrance to the simple phenomenon of plane reflection. Like churchyard ghosts, which resolve themselves into a bush or a gravestone, or are found to be composed of a hollow turnip, stick, and sheet, so this mirror ghost resolves itself into an optical illusion, not to be found when seriously hunted for.

"Light is composed of vibrations of luminiferous ether." I have seen that before, but don't like it. The phrase is beautiful, but the value of a phrase is in its meaning and consequent adaptability, so we will analyse it to find out if it is able to resolve the question, "What is light?" The first of the three words need give us no trouble; it is evidently used here in its generally accepted sense. The word ether "is a name given to the medium which is assumed in astronomy and physics as filling all space, and capable of transmitting energy, a necessity of the theory of light on the hypothesis of undulations." The scientists knew what they wanted, and have invented a something admirably adapted to their needs, and the intelligent explanation that it enables them to give of a thousand phenomena of nature argues strongly in favour of its being there. They have endowed it with certain properties, as infinitesimal density and enormous elasticity, with consequently the capa-

bility of carrying energy from suns to their planets, and with equal facility transmitting Marconi messages over land or sea. So ether is an assumed something—a hypothetical what-is-it. The meaning of luminiferous is the difficulty. Webster gives "producing, light yielding"; Latham, "conveying, generating light"—the "Imperial Dic."

As it is not claimed that this something either produces, generates, or yields light, we may take it that the word is used in the sense of carrying, and that the carrying medium is as distinct from its burden as the pigeon is from the message which it carries. We may put the sense of the phrase, then, into simple English, thus: Light consists of the vibrations of light-carrying what-is-it. As to the origin of the vibrations and the manner of transmitting I have given my conclusions for what they are worth in the "E.M." Vol. LXIII. pp. 303, 327, 354, 400, 449, and 238.

This hypothetical something is called ether, a bugbear to Brewster and abomination to Leslie, and giving it a name which indicates but a small part of the load it has to transmit, shows the immaturity of idea in its early conception, and since it has to transmit the totality of motion which it receives from disturbing bodies, it might be more correctly named energy carrying or transmitting ether; but as it is distinct from this energy, it is questionable whether any adjective is necessary. Ether is all-sufficient. Mr. Naylor's explanation based upon the provisional name of a hypothetical something can hardly be deemed satisfactory.

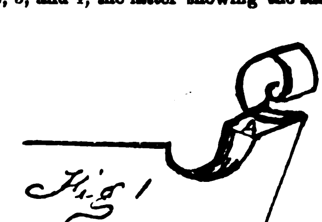
One proof that there is no light outside the eye is found in the fact of a ray of vibrations crossing a dark chamber or box without making its presence visible, unless received directly, or deflected into the observer's eye (see "E.M." Vol. LXII. p. 261). It is answered to this that the light is not on the sides but at the ends of the vibrations, as when they enter the eye, or strike a body, and are reflected. Easily disproved: place a light in front of a mirror so that its rays fall upon it perpendicularly, and if the ends of the rays are light, we should find an image of the source of the rays, and focus it on the face of the reflector. This, I showed in my reply, we cannot do. Here is one of the uses of showing that there is no image on the face of the mirror, nor in it, nor behind it.

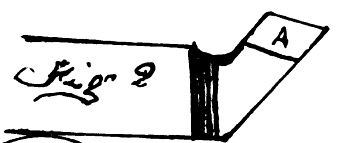
In the well-known experiment with the dead eye, using a bullock's, more easily obtainable than a rabbit's eye, I have seen the inverted reflection of a lighted candle, but it is evidently off the posterior surface of the crystal lens, and very faint. From the fact that some of the rays reflected into an eye are sent back to the eye of the observer behind it, I see some possibility of success in the experiment I suggest; but the distance between the eye and instrument is too short to allow of measurement of the focal distance. Notwithstanding Mr. N.'s dictum, I do not yet consider it as hopeless.

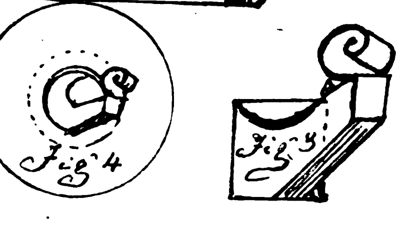
Fred. H. Ewers.

ON ANGLES OF SLIDE-REST TOOLS.

[43115.]—There is no tool that I am aware of that presents its proper cutting angle in a proper position, but the sketch tool, of which I forward sketches 1, 2, 3, and 4, the latter showing the same







for a boring tool. It is the easiest to forge, and can be used by a practical man for anything. It is the tool that I have used for years, and I have been informed that it is the tool used for testing the truth of lathes, before they are passed, and the only tool that can be used for these tests. Fig. 1 is the side—i.e., near side view, Fig. 2 is the top, Fig. 3 end on facing work, and Fig. 9 shows one for boring tool in position.

Jack of All Trades.

POISON IN FISH.

[43116.]—I am very sorry for "L. C." and his family, but am even more surprised at his people partaking of a single fresh whiting than at the evil consequences. Is there not a mistake in the name of the fish? One whiting is usually not more than enough for one person.

Glatton.

MASSES SMALLER THAN ATOMS.

[43117.]—Apropos of the statement quoted by "Density" (p. 383), that molecules are supposed to be all of the same size—a statement universally accepted hitherto—is this assumption in any way affected by Prof. J. J. Thomson's discovery (see p. 128) that atoms are not, as usually supposed, the smallest forms of matter?

Glatton.

USEFUL AND SCIENTIFIC NOTES.

There are fewer applications for letters patent in this country than in 1898. This is largely accounted for by the decrease in the number of patents connected with cycles.

The British Journal Photographic Almanac, 1900, edited by Thomas Bedding, F.R.P.S., consists of 1,516 pages, and is the 39th yearly issue. The principal contents include an article on "Stereoscopic Photography," by the Editor; about ninety contributions on practical subjects by prominent photographers; a series of pithy "Practical Notes and Suggestions of the Year"; an "Epitome of Progress during 1899," giving a *résumé* of the latest important discoveries and advances; miscellaneous information, many illustrations, and the completest collection of photographic formulæ and recipes ever gathered together in one volume. In its many hundreds of pages will be found a mass of information of use to all photographers, professional and amateur.

The "Firewalk" of the Tonga Islands.—In the *Englishwoman* an account is given of the "firewalk," as practised in the Tonga Islands:—A pit about 26ft. long by 16ft. wide was filled with large stones which had been heated for some 36 hours with logs of burning wood placed among them. Men with long poles were removing the blazing wood from the stones, so that there should be no flames. We could all feel the great heat reflected from the stones at a distance of ten or twelve yards, so there was no deception in the matter. A procession of about 40 or 50 men, and a few women, adorned with flowers and fringes, advanced through the leafy glade and halted at the edge of the pit. The leading fire-walkers carried large branches of ti leaves, with which they beat the ground in front of them, and after pronouncing some mystical words, they stepped down on to the hot stones and marched solemnly across the pit with all their followers, singing or chanting the whole time. The procession then marched past us to the edge of the glade, and retraced their steps to the pit, which they crossed at least twelve times. One or two women fell down, and were rather severely scorched. The men said the principal discomfort was the heat on their faces. No one could tell us the real meaning of the performance, and we only heard that it was an old superstition of heathen days.

Fossil Dinosaurs of Wyoming.—There have been set up in the American Museum of Natural History a series of fore and hind limbs of carnivorous and herbivorous dinosaurs from the great fossil beds of Wyoming, whence they were resurrected, singularly well preserved, by scientists from the museum. Dr. J. L. Wortman, who conducted the operations in the Bone Cabin Quarry, where these magnificent relics were found, had perfected field methods by which every piece is kept and transported in the position in which it was found, and this, supplemented by the methods used by the museum authorities, have brought it about that the world's knowledge of those vast and strange creatures, the dinosaurs, soon not only will be practically complete, but almost exact. In the Bone Cabin Quarry, the bones of all of the most characteristic dinosaurs were found mingled, and among them were discovered nine almost priceless objects—six upper limbs complete and three forefeet. In an interesting paper prepared for the museum, Henry Fairfield Osborn describes these finds, and explains their great importance to the scientific world. He says that the late Prof. O. C. Marsh had described five genera of flesh-eating dinosaurs—allosaurus, the largest of the flesh-eaters; creosaurus, a smaller allied form; laborsaurus, still another type; coelsaurus, a small animal distinguished by hollow bones; and ceratosaurus, a large animal with horns on its nose. Two of the huge legs are believed to be those of the allosaurus, or of the creature to which the allosaurus was allied most nearly, the megalosaurus.

REPLIES TO QUERIES.

*** *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[96922.]—**Stylographic Ink.**—I invested in a fountain pen, and have been in a terrible fog relative to inks. At last I made up one, as follows:—A few scraped shavings of curd soap, about as much as you could lay upon a threepenny piece, is placed in a teacup, and about 2oz. of boiling water put upon it. When cold, put about ½oz. of "unsweetened" to it. Bottle it for use to rub up with Indian ink, or make your bottle up. This has more than one advantage—it is anti-corrosive, it flows very freely, is black, drys quick, and, if wetted, it will not blur or run, as the paper may be soaked in water (as drawings made by this can be), and strained upon canvas. This is written with some that has been in my pen for over two months put by, and occasionally used to test its keeping qualities. It is indestructible, as it is a carbon ink.

Jack of All Trades.

[96973.]—**Sand-Blast.**—The sand-blast was described in these columns when it was first patented, and it has been used for many purposes since—chiefly, perhaps, for abrading the surface of glass. What "Regent's Park" (p. 322) means by a "vertical tube 2ft. high by 60in. long and 1in. diameter," is best known to himself. The sand-blast can be used with a fan, of course; but unless the work in hand prevents, steam is generally used, as in sharpening files. As to the query, it might be pointed out that when the term "blast" is used that implies that "power" is required. If querist stated the purpose, he would no doubt obtain full particulars.

M. T.

[96975.]—**Fishing Lines.**—"Angles" says he would be glad to learn of a good dressing for fishing lines. He can find many suggestions by searching the back volumes, and knowing the material of which his lines are composed, he can form his own opinion. Had he stated of what his lines are composed, he would no doubt have received many replies. Lines of silk, cotton, or hemp, are, I think, best treated with boiled linseed oil; but they require careful drying, and should never be put away until dry. I do not think there is any better line than the usual oil-dressed silk.

T. L.

[96977.]—**Varnishing Calico.**—For the special purpose what is known as rubber varnish is best; but the calico must be damp or must be dressed with liquor in which a little soap and some linseed has been boiled. The varnish is applied while the calico is still damp. For ordinary purposes a copal varnish will suit; but I suppose "W. M." knows that balloons are not generally made of calico.

M. T.

[96992.]—**Petroleum-Drinking.**—My query (p. 282) referred to a statement that petroleum drinking is at present prevalent in Paris, and asked why it is taken, in what form it is taken, and what are its effects. The reply on p. 323 may have been written with a "good intention," but it does not answer my questions. May I ask whether it is true that some Parisians have taken to drinking petroleum?

W. A. D.

[97003.]—**Rothwell's Engines.**—The replies to this query are most unsatisfactory, because the question deals with a simple matter of fact, and if that cannot be answered correctly, what price "ancient history"? Mr. Stretton says, on p. 302, that the firm had a factory (the Union Foundry) at Bolton; "Regent's Park" (same page) seems to be in doubt, but thinks it was at Bristol. I have little doubt that Mr. Stretton is correct; but what must the querist think of replies so contradictory?

M. E. V.

[97071.]—**Age of Violin.**—Perhaps by Alexander Hardie, sen., who chiefly lived about Dumfries and district. "Scottish Violin Makers" (Kohler) gives "A. H., sen., 1776-1855," and "A. H., jun., 1811-1890." I know two violins by the former—one is stamped "A. Hardie" on back at junction with neck. The best Strathspey player I have heard preferred this violin. From this point of view the tone is excellent.

Pont Hyle Fan, Rhayader. J. Matthewson.

[97121.]—**Geometrical.**—Draw a line from P^1 perpendicular to the base. Make the point where this line meets the base the vertex, and P^1 the focus of a parabola. The curve will cut A B at P^2, the point required.

J. Matthewson.

[97151.]—**Oil-Engine.**—York paving has a crushing weight per square inch in tons of 2·56, 1½in. length of cube; Darley Dale ditto 3·16 tons, 2in. length of cube; strong Yorkshire (mean) ditto 4·38 tons, 2in. length of cube; Park Spring ditto 3·38 tons, 2in. length of cube; all above sandstones. Limestones: Ketton rag ditto 4·01, 2in. length of cube; Listowel ditto 8·33 tons, 1in. length of cube; Longhome ditto 7·68 tons, 1in. length of cube; Moyne ditto 8·03 tons, 1in. length of cube; Irish, various, 5 to 14 tons ditto, 1in. in length of cube, &c.

The safe working of leather belting is 20lb. per inch in width, for each $\frac{1}{10}$in. in thickness of the belt, or 40lb. per inch in width for $\frac{1}{5}$in. in thickness. The breaking strength per square inch of section of best quality leather belting is 3,360lb., ditto best quality stout stitched cotton belting is 6,800lb., ditto of best woven solid cotton ditto is 10,420lb. Foundations (dynamo): If machine is properly proportioned, and if fitted with rigid brush brackets, heavy foundations are not necessary. Many dynamos perform well when merely bolted to flooring of factory, a sheet or two of vulcanised rubber or asbestos being interposed. If placed in basements, keep their foundations separate from house-walls. Weight of engine: Divide the diameter of cylinder in inches by 46 for tons, for cwt., by 2·3 for approximate weight; 50 volts × 4 ampères = 200, or less than $\frac{1}{4}$H.P. electrical, 746 units being 1H.P.; hence your dynamo cannot be very large or heavy. Small gas-engines use more gas as a rule than large ones; possibly 18 cubic feet per indicated H.P. in large, and 25 cubic feet in small. Average pressure about 70lb. per square inch on piston. See "Electric Light Fitting, by Urquhart." No doubt Stuart and Lloyds are likely makers for both engine and dynamo. By a curious coincident *Work* for Dec. 2 gives for gas-engine foundation: Solid mass of Portland cement concrete, solid brickwork also used, but larger excavation required. Best shape as near cubical as possible. If site is near wall, lay concrete floor under footings of wall, and make it form part of same mass as engine foundations. Stone bed-plate between concrete and engine-bed. Holding-down bolts, with anchor-plates at bottom end buried in concrete, placed in their exact positions with aid of templet marked off bed of engine's upper ends, screwed, of course, to secure nuts. Another method is to cast holes in concrete through which bolts pass downwards, in which heads of bolts may be at top, and nuts are tightened up through hand-holes at bottom ends; but this needs a trench for access. Cotters at bottom ends of bolts are easier to adjust than nuts. REGENT'S PARK.

[97177.]—**Cold Feet.**—You had better persuade your lady friends or relatives to knit you some thick woollen socks, or, better still, stockings, and when watching the slide-rest tool in future keep your feet well on the move. You need more exercise to keep up the circulation, and this is exactly what you do not get at the lathe. If you could give the striker man at the forge a spell you would not suffer with cold feet—that is, of course, provided you are in good health. T. J. LENEY.

[97154.]—**Bone Bearings.**—It is a very old saying "That one tale is very good until another is told," and I am sorry that "Hardwood Turner" should have found them a mistake; but I know that there is a mistake somewhere. The saddle-lathe that I have mentioned, from '47 to the fall of '49, I spent many long days with, doing heavy and light jobs in it without any signs of fatigue. The centre was 15in., and I have turned small bone fittings in it for fancy cotton-stands and workbox-fittings, and many small skittle-pins $\frac{3}{4}$in. high, little more than $\frac{1}{4}$in. thick, with a tail or pin to it a bare $\frac{1}{16}$th and $\frac{1}{16}$ths long, for cribbage-pegs, for cribbage-boards, trenchers, or waiters, 2ft. in diameter, and naves for wheels for coaches, carts, and waggons of wet elm. If that was not enough to test them, I do not know what should be. The old chap who it belonged to, I became acquainted with in '40, when I was out of collar. He gave me permission to go and make myself at home there, and do any jobs I could pick up. You must understand that I had been suffering from a long illness—rheumatic fever. He used to come in when I was at work, and any jobs that he had got I would take and do for him. It kept me from rusting. He used to say "I cannot make out how you manage to make the old thing 'gee.' Does it never pull up?" My answer was "No." "Well, well, it is always pulling up with me," he said. Well, I then had no notion of what it was running in; but when warm I smelt a most delicious smell of ham one day. Some theatricals came to town, and, in their combats, i.e., stage-fencing exhibits, they broke some of their swords. At a country smith and wheelwrights, a very little way off, the things were taken to have a new tang welded on. I was at the shop door looking on when the master, looking up, said to me: "Jack, how is that job to be jobbed?" "Oh," I says, "that is easy enough." "With taking the temper out?" he says. "Yes, that is all right." "Well, look here, I will stand a gallon of best ale if you will show me how to do it. Can you do it?" "Well," I said, "I will try if you will let me have the tools and fire." I off with my jacket, and up with my shirt-sleeves. "Is there anything you want? There is sulphur, borax, salammoniac, soda, plaster of Paris, &c." "Nay, I'll have none of them. But some clean silver-sand and two good-sized, long, raw potatoes." "All right." After a few minutes he returned, and with them. "Now, what are you about? You are not a-going to use, or weld the sword tang on with those potatoes and sand?" "I certainly am. I shall not attempt to do it without." He was a bit of a wag in his way, and, scratching his head, said: "Ah! put it in your pocket, eh!" "No," says I, at the same time taking hold of a potato and splitting it. Ran it down to within a short distance of the tang end. Having prepared my fire the while, I mounted the sword tang downwards, through a hole in a hollow fire. "Damn," he said, "but that's good." Well, I done the job, and more than one got tight over it—i.e., elevated. I was free of that shop to do what I liked in it, and free of the scrapheap for material ever afterwards. One day I took home a pair of naves for cart-wheels. "Look you here," he says, "you are an engineer, turner, fitter, or something of the sort. Can you rig me up a lathe?" "Well, yes, but I have no shop or materials." "Just so, then look around and hunt up what you are likely to want." I did so, and fitted him a 7in. lathe or somewhere there, about 6in. or 7in. When done, it went a treat; the old gentleman, my friend, seeing it, tested it, and saw me working it. He was very inquisitive. "What is that bearing made of?" he asked. "Well, steel, and hardened as hard as a stone," was the answer. "Ah!" he says; "and you made it. Would you mind altering of mine, and put a steel bush in mine? The while you are a doing of mine, I can come here, I know, to do what I want." So I dismantled his lathe, and was somewhat staggered by the look of the cone, a perfect black polish, not a scratch or rib in it, a bearing 3in. long. I started pegging away to get the cone-bush out, and when it came, I found it to be a ring-bone of a ham; it had been nicely smoked too. Well, I showed him the affair, and said: "You should never have this altered; it is a mistake, and in a very little time you will find it out. Well, as you like, but it is the most beautiful bearing I have ever seen, or anybody ever saw. Shall I put it back?" "No, no; I want a hard steel bush for it, it always was a nuisance." "Well, don't blame me for what will surely come; the day is not far off when you will be truly sorry for it." I fitted it up, and work having accumulated, I done a good sample of it, when I was called away to another job. In a week he found his mistake out; his bearing had seized, and no amount of oil would make it move in any sense, and when I got back, his bearing was galled all to pieces, and no grinding or anything else would put things right. He offered up a prayer. "The old bush—put it back again." "But that is impossible; the spindle wants re-turning." "Very well, turn it, and put the bush in." "But it will not fit." "Well, make it. Do so. Where is it?" After hunting, he recollected that he had thrown it into the fire. "But we will get another bone and make a bush." But the other lathe had changed hands, so I had no plant to do the job, so I ground it the best I could for a makeshift, until I could see my way to alter it. Day after day he complained of it. The filthy black mess and the grinding and continued cutting of the bearing was cruel; but I could not help him, as I was called away to a job in the Midlands, and I saw the poor old chap no more. Now, if your bone was not prepared, the gelatine would not let the bone dry properly, and when it got hot, which it certainly would, it drives all the grease out, and the sweating would pull you up sharp. Your cone, perhaps, is very shallow and binds. The principal cause of the old gent's pulling up was because he insisted in using the muck that is sold for neat's-foot oil, which is charged with gelatine. When I used the lathe I always used lard. JACK OF ALL TRADES.

[97156.]—**Reflecting Stereoscopes.**—For viewing large pictures may be constructed in three different ways. I will give particulars first of Prof. Wheatstone's design, and then two others by myself. In Fig. 1 two mirrors are placed at right angles to each other in the position shown. The

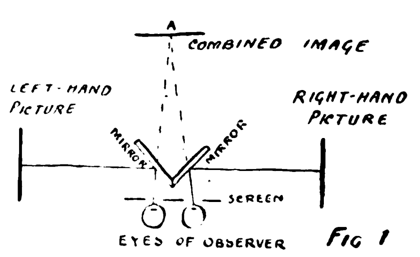


FIG 1

eyes looking into these see the combined image of point A, the same distance behind the mirrors as the actual pictures are from the mirrors. In Fig. 2 let AB represent the two dissimilar pictures, GH the eyes of the observer, and CD the two mirrors, the essential parts of the apparatus. On placing this to the right eye H, the observer will see at point A the image of B in the mirror C, by reflection from B to D, D to C, and C to A. A stereoscope constructed on this principle may be used for any size pictures; but, of course, the larger the pictures the greater must be their distance from the observer. In Fig. 3 four mirrors are employed. The actual dissimilar pictures being situated at A and B. They are seen by reflection at point F. In this instrument the

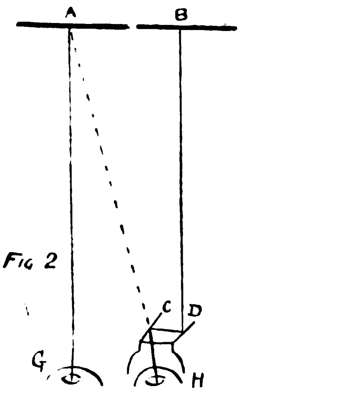

FIG 2

two outside mirrors are fixed, and the two inside ones fixed back to back, and so arranged that they may turn on a centre pivot. Hence, by the move-

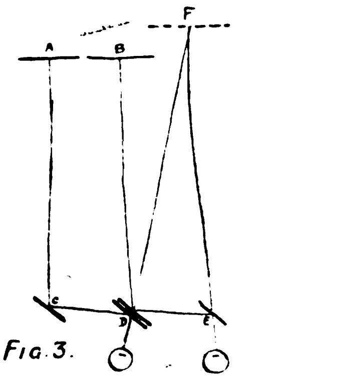

FIG 3.

ment of this centre pair of mirrors the reflected images of A and B are shifted together. THEODORE BROWN.

[97178.]—**Joint and Piston Packing.**—The quickest and cleanest method to make a cylinder cover-joint is with thin rubber insertion. This consists of indiarubber sheet in the centre of which runs a sheet of canvas, the two being perfectly amalgamated. Another good joint which answers equally as well for rough surfaces as machined is made with tar-band and white-lead, mixed with red-lead to the stiffness of putty. Smear the tar-band, apply paste to joint, then run a few rings of tar-band on paste; put on cover, screw up nuts regularly in succession to produce equal pressure all round. This makes an excellent joint for man and mud-hole covers in boilers. To pack stuffing-box on cylinder run nuts of studs, slide the gland along piston-rod, then take spun-yarn well greased and wind round piston-rod two or three times, force into box tightly with caulking-tool, then wind again, and so on till full; bring gland to front of box, put on nuts, and screw up a few turns. In using chalk packing of $\frac{1}{4}$in. and above diameter, I cut it into lengths that will just barely go round piston-rod once, being careful to place joints of rings at different positions in stuffing-box, tighten up gland nuts from time to time to compensate for wear. RICHARD HUDSON.

[97188.]—**Asbestos Packing.**—Asbestos sheet or a skin best; but asbestos powder or filling would practically answer same purpose, if thick enough. REGENT'S PARK.

[97189.]—**Razor - Sharpening.**—Hollow-grounds are usually done with small corundum, emery, &c., wheels. Very often on Continent by Germans. Expect you would have ill-success if not accustomed to it, steel being worked very thin, and many blades giving out ere done. If edge is rounded by stropping, can be brought to flat bevel on edge by placing on perfectly flat hone with little thin oil—lard or machine—letting back rest upon stone, and, with small circular motions of hand, without pressure, grind down bevel until stone-marks meet on both sides in a fine feather edge. For strop use fine, even calf-skin glued to piece of wood, or use canvas strops sold at cutlers' and tool shops. Paste of rouge and olive-oil, or oxide of tin and oil. REGENT'S PARK.

[97190.]—**Launch Boiler.**—The reason for the boiler not steaming well is, no doubt, because the tubes are clogged with soot. Possibly the heating surfaces inside boiler are covered with mud and

scale. If a water-tube boiler, the inside of tubes may be furred up. Clean out boiler with strong soda water, after which thoroughly wash out with plain water. IGNITION TUBE.

[97190.]—**Launch Boiler.**—Why not clean it inside and out. Put in about 1lb. of pure soda, boil with about 5lb. of steam, blow right off altogether; then refill, raise steam again, and allow to cool off before blowing off. The sediment will not then set hard, and can easily be washed out. MONTY.

[97192.]—**Dynamo.**—As you do not give the type of armature, whether drum or ring, nor the gauge of the present wire on the armature, it is not easy to assist you satisfactorily. If the machine were mine, I should unwind the armature, take the gauge of the wire and its weight. I should then rewind the armature with the same weight of a wire having ten times the sectional area. Without rewinding the field-magnets, and presuming these to be shunt-wound, it would probably be necessary only to put the two F.M. coils in parallel to bring down the resistance sufficiently. The speed would certainly not exceed 1,650, and probably would be less. S. BOTTONE.

[97194.]—**Carsak Cell.**—To MR. BOTTONE.—As far as its polarisation tendencies are concerned, the above behaves just like a good Leclanché. It polarises in about twenty minutes, if full current is taken off, and requires a good long rest to recover itself. S. BOTTONE.

[97195.]—**Sizes of Wire.**—To MR. BOTTONE.—As there are 88 yards in ¼lb. No. 24 and only 7½ yards in ¼lb. No. 14, you would need use 11lb. odd of No. 14 to get the same result with the same battery power in the primary. No. 36 runs 1,650 yards to the pound, or practically ten times as much as No. 24; hence 5lb. of this latter would be required. The gauges mentioned are therefore totally unsuitable for a coil of that size. S. BOTTONE.

[97196.] — **Science and Art Department Certificates.**—Write up to the secretary of the above department, stating you intend to become a candidate for examination. He will send you forms, &c., for you to fill in, and give you information as to where you can be examined locally. You can also purchase complete sets of questions that have been propounded in previous years. These will help you very much, in showing you what kind of knowledge you are expected to acquire. Then read up, and, above all, experiment; this is the key to success—practical knowledge. Do not forget to enroll yourself in good time, and to send up your fee for the exam. S. BOTTONE.

[97196.]—**Science and Art Department Certificate.**—You would have to apply to Science and Art Department, South Kensington, about January, for permission to sit. Exams are held annually in May. Fee for each, 2s. 6d. You would not have to attend classes, and the Department would inform you of the nearest centre where you would be required to sit for examination. Get "Science and Art Directory for 1900," price 1s. 6d. It will explain much, and give syllabus of subjects. Suggested books for these exams: Jago's "Chemistry," elementary and advanced, or Newth Thornton's "Elementary Physiography," and Simmons's "Advanced Physiography"; Poyser's "Elementary and Advanced Electricity," or Silvanus Thompson's "Electricity." Write to Science and Art Department—they will give all information. CLARA.

[97196] — **Science and Art Department Certificates.**—The querist can "sit" at any of the centres appointed for examinations to be held. He should procure the "Directory" (price 6d.) published by Eyre and Spottiswoode, and to be had through any bookseller. It is a pity that "Lux" cannot attend some class, as he would probably benefit by contact with other students. For example, what does he mean by "I teach myself"? How is that possible? M. T.

[97197.]—**Change of Wheels.**—Rule 1: Place number of threads per inch of leading screw for numerator, and number of threads per inch of screw to be cut for denominator; add cipher to each, which gives required change-wheels. Example: To cut screw eight threads per inch, with leading screw two threads per inch.

$$\frac{2 \text{ threads leading screw}}{8 \text{ threads in screw to cut}}$$

Adding cipher $= \dfrac{20 \text{ driver}}{80 \text{ driven}}$ Wheel representing numerator is placed on lathe spindle; wheel representing denominator placed on the leading screw. Rule 2: When number of threads to be cut is uneven—say 2¾ threads per inch—multiply the whole number by the denominator of fraction, and multiply also number of threads per inch of the leading screw by the same multiplier.

$$\frac{2 \text{ threads per inch in leading screw} \times 4}{2\frac{3}{4} \text{ threads per inch in screw to be cut} \times 4}$$

$$= \frac{8}{11}. \text{ Add cipher} = \frac{80 \text{ driver}}{110 \text{ driven}}$$

When numbers of teeth of wheels found by this rule are too large, they may be reduced by dividing them by any suitable common divisor; and, if too small, may be increased by multiplying by any suitable common multiplier. When double train or four change-wheels are used, fix in any three wheels for lathe-spindle and stud-wheels, and fourth or leading screw-wheel may be found by Rule 3: Multiply number of teeth in wheel on lathe-spindle by ratio of screw to be cut and leading screw, and by number of teeth in second driver or stud-pinion, and divide the product by number of teeth in first driven wheel. Thus, to cut a screw of 16 threads per inch, with a leading screw of two per inch, the ratio is 8 to 1. Lathe-spindle wheel 20 teeth, stud pinion or second driver 50 teeth, stud-wheel or first driven wheel 80 teeth; required number of teeth in leading screw-wheel. $\dfrac{20 \times 8 \times 50}{80} = 100$ teeth. Above will cut right-hand thread. To cut left-hand thread:—Place another wheel between a driver and a driven wheel to reverse the motion of the saddle. Rule 4: The wheels may also be found by assuming pair of wheels in conjunction with Rule 1, say, $\dfrac{100}{100}$, and by dividing one of the drivers and one of the driven wheels by any suitable number. Thus, to take screws in last example—

$$\frac{2}{16} \quad \text{Add cypher} \quad \frac{20 \text{ driver}}{160 \text{ driven}}.$$

Assume pair of wheels $\dfrac{100 \text{ driver}}{100 \text{ driven}}$, then, by dividing first driven wheel and second driver by two, the required wheels are $\dfrac{20 \;\; 50 \text{ driver}}{80 \;\; 100 \text{ driven}}$. Rule 5: Proof of correctness of change-wheel when screw to be cut is finer pitch than leading screw, multiply driving-wheels together, multiply driven wheels together, and divide greater product by lesser. The quotient, multiplied by number of threads per inch of leading screw, gives number of threads per inch of screw to be cut. To prove wheels in last example, $\dfrac{80 \times 100}{20 \times 50} = 8 \times 2 = 16$ threads per inch in screw to be cut. Coarse pitch screws. Rule to prove: Multiply driving-wheels together, also driven wheels; ditto product of driven wheels by number of threads per inch of screw, with which product divide product of driving-wheels. Thus—

$$\frac{50 \times 100 = 100}{20 \times 25 \times 25 \times 2} = \frac{500.000}{25,000} = 20\text{in. pitch, \&c.}$$

See W. S. Hutton. REGENT'S PARK.

[97198.]—**Screw Gear-Wheels.**—If you refer to reply No. 96711, p. 212, Oct. 13, 1899, you will get the lines and for the angle-plate to cut them. You must not attempt to cut them between centres as a screw with your change of wheels, or you will break your wheels up. Why not make angle-plates to put upon surface-plate of lathe? There is not much trouble, and then you can cut them with a single point in the rest. Your wheels are not in it the other way you speak of. You might manage the 20 teeth, but the 10 the angle is too much for your stud; it would sheer it off, I am afraid. In the page I have mentioned is every information that ought to put you right for the job. If you don't comprehend, state your difficulty. The price asked for the cutting of these up would more than pay you for fitting up angle-plates for the job, and you would not be tied for pitch, and, therefore, the diameter of wheels. JACK OF ALL TRADES.

[97199.]—**Hertzian Telegraphy.**—To MR. BOTTONE.—(1) No. Lead in with ordinary copper wire. (2) It does not matter whether the home coherer does act during transmission, as it is not generally prevented from acting; but it can be prevented by shielding with a metal cover, and by metallically connecting the two wings. (3) The waves can be directed by means of parabolic reflectors, as even by lenses made of pitch; but the usual plan is to use wings and syntonisers of different capacity both on sending and on receiving instruments when speaking to different stations. It is seen that there is room for much improvement in wireless telegraphy. S. BOTTONE.

[97201.]—**Dross from Type Metal.**—This is usually run out either by crucibles or reverbatory furnace. J. W. Woolford, 73, Boundary-road, Barking, has a patent furnace specially for this work. W. G. CLEARE.

[97201. — **Dross from Type-Metal.** — Have small cupolar furnace, 3ft. or so diameter, and 4ft. high, or larger if you prefer, or smaller. REGENT'S PARK.

[97202] — **Gas-Engine Piston Rings.** — A piece of cast-iron tube of the right size is gripped in a chuck and turned on the inside, after which the outside is roughed down to nearly the proper size. It is then cut off to the right width by a parting tool. The ring is then put in a tool and clamped up tightly, and driven between the lathe centres and the finishing cut taken; it is then cut in two to make it springy, and is then ready to put on the piston. IGNITION TUBE.

[97203.]—**Ivory Dust.**—Immerse in somewhat diluted solution of a mineral or vegetable acid. Maceration quickened by heating in water bath to 95° to 100° Fahr. Strain and compound with three-quarters of volume of ivory glue free from excessive moisture by air-pump. Mix mass with solution of copal in alcohol, and pour into sulphur moulds where it soon becomes hard. Has appearance of genuine, then plates of it as translucent, and can be dyed. Magnesite or petrifite being also a very plastic and mould-taking material, white in colour, mixes with almost anything, would be a useful adjunct. The price, however, is somewhat high, say 6s. or 7s. per cwt. at Blackwall depot. REGENT'S PARK.

[97203.]—**Ivory Dust.**—Clean ivory dust stewed makes excellent jelly, and the refuse is a valuable manure to mix with potting mould. I suppose it is now worth more than it was twenty years ago, when I used it for making jelly. The ivory-turners and cutters are glad to get rid of it, as in heaps it is liable to heat and spontaneously combust, especially if it is that obtained by the cutting of ivory slabs for making pianoforte keys, as they are cut when wet. Clean ivory dust has a considerable market value, and is readily sold to the restaurants and to chefs. I do not think it can be moulded up into "objects" with so much profit. Several other materials are cheaper. S. R.

[97204.]—**Daniell Battery.**—(1) No, because the internal resistance is so great. It can be done, but the cells must be very large—say 1gal. size. (2) 1·079 volt. (3) Resistance varies with size of cell, distance of elements apart, &c. Average for 1pint size 10ohms. (4) By melting zinc, and adding to it its own weight of mercury, stirring with a stick, and allowing to cool. S. BOTTONE.

[97205.]—**Inkblots.**—Put on concentrated solution of chloride of lime, eau de Javelle, or oxalic acid—either will do. As soon as marks disappear, blot off as quickly as possible with clean blotting-paper, and wash thoroughly, as any of the above will spoil a print if they are not removed soon. The exposure depends so much upon local circumstances, sun, time, &c.; but, as a rule, exposure for snow is only about half what it would be without snow. CLARA.

[97207.]—**Multiplate Wimshurst.**—To MR. WIMSHURST OR MR. BOTTONE. —If by trunnions you mean the bearings, then I can only say that in all cases the moving parts should be bushed with either brass or steel tubes, these, of course, being covered with wood. The main driving-spindle must be of steel, and this has a wooden sleeve round it, which carries the wooden pulleys. The holes in which this spindle rotates must be bushed with brass tubes. The upper spindle is also of steel; but, as it does not rotate, the bearing holes do not require bushing. On the other hand, the bosses which bear the plates do rotate, so they must be bushed. All this woodwork should be polished after having been soaked in melted paraffin wax until the pores are well filled in. As the upper spindle is in the centre of the plates practically at a neutral point, it does not affect the machine injuriously. But keep the standards as far as you conveniently can from the first and last pair of plates. S. BOTTONE.

[97207.]—**Multiple Plate Wimshurst.**—In reply to "T. M. C." By far the best bosses for these machines, are made of well-seasoned yellow pine with brass tube through its centre. The best way to proceed is to select a length of polished steel rod of suitable size and length; then obtain a stout brass tube which fits the spindle closely. Cut this tube into suitable lengths. Next cut up your pins into suitable lengths, and size to form the boss. Bore a hole through these "length" way of the grain, and force in the short lengths of brass tube; put a mandrel through the tube, and then turn up the boss, leaving a slightly projecting spigot to fit the holes in the glass. Next get some vulcanised fibre about ⅛in. thickness, and cut-out washers; the hole in these fits upon the tube. This washer cements to the glass with Chatterton's compound, and takes the screws which attach the glass and washer to the boss. It is disadvantageous to have any more metal than the spindle, the brass bush, and the screws. J. W.

[97208.]—**Voltage.**—Voltmeter A showed the voltage or pressure needed to drive the current through the resistance of the lamp and the battery in circuit. Voltmeter B showed the lesser pressure needed to drive the current against the E.M.F. of the battery, and its resistance only. The "fall of potential" in the lamp, &c., was 69½ volts or thereabouts, and that in the battery 10½. Querist might possibly state his difficulty more in detail.
Belfast. J. BROWN.

[97209.]—**Incandescence.**—To MR BOTTONE.—Mr. W. H. Preece made a series of experiments to determine the ampères required to fuse wires of different metals of several sizes. Tables showing these may be found in almost all textbooks. Platinum wire 1 millimètre in diameter takes 20 amps. to fuse it. One foot of this wire has a resistance of

about $\frac{1}{10}$ of an ohm; hence any battery giving 2 volts, and having *no* internal resistance, would fuse it, since $2 \div \frac{1}{10} = 20$. But no such battery exists. We have several, however, the internal resistance of which is below $\frac{1}{10}$ ohm. In practice, nothing would be better than two large-capacity accumulator cells in series, say L 11 or L 15. The next best would be two chromic-acid batteries, gallon size, in series. S. BOTTONE.

[97210.]—**Steel-facing Copper Plates.**—To MR. BOTTONE.—Your 50v. dynamo is utterly unsuited in every way for this work—first, because the voltage is too high; second, because you do not wish to use more vats than one to balance this; third, because it is series-wound. Read Bonney's "Electro-Plater's Handbook" for fuller details. S. BOTTONE.

[97211.]—**Cockroaches.**—The querist can, with a little perserverance, rid his kitchen of cockroaches. He should put down a few heaps of the well-known insect powder—about a tablespoonful here and there—and, when the morning arrives, he can sweep up the stupefied specimens of the genus Blatta, and consign them to the flames. I live in a locality where cockroaches spread in a very lively manner; but we have cleared the house, and when we see a fresh arrival down goes some insect-powder in likely haunts (warm and damp), and we soon get rid of the pests. The insect-powder is the ground flowers of the Pyrethrum roseum, of Dalmatia and Asia Minor. It is well known. S. R.

[97211.] — **Cockroaches.** — Borax, red-lead, carbolic acid, corrosive sublimate, poke soot by themselves or in solution are enemies to such; but it is rather doubtful whether in the form of mortar or ordinary make they would have original effects can only be the test of experiment. REGENT'S PARK.

[97213.]—**Chaff-Cutting.**—In your case I should use a 1¼in. hemp rope drive, using pulleys about 5ft. diam. at least, with supporting pulleys and an idle tension weight pulley at end to take up slack and avoid resplicing, which is always a trouble. This is cheapest and best way to do it. MONTY.

[97213.]—**Chaff-Cutting.**—The simplest means of working your chaff-cutter would be by electricity. You would require a small generator and motor, cable, &c. It would not be cheaper in the end to buy a small oil or gas engine, especially as you have a steam-engine.

WEBSTER MICHELSON AND CO.
Dudley. Electrical Engineers.

[97213.]—**Chaff-Cutting.**—Forty yards is a good distance. If you have roller bearings on your cutter instead of common bearings, the friction of sliding is eliminated. The safe tension of leather belting is 20lb. per inch in width for each $\frac{1}{16}$in. in thickness of belt, or 40lb. per inch in width for each ⅛in. in thickness. Breaking strain per square inch section of best leather belting is 3·360lb.; of best quality stout stitched cotton belting is 6 800lb.; of stout solid woven cotton belting is 10·420lb. One would think a suitable oil or gas-engine for the cutter would be best. REGENT'S PARK.

[97214.]—**Softening Brass.**—Both brass and copper are softened by heating and hardened by pressure. In the case of brass, however, I find that heating to a red in a fire often spoils it—probably some action between the zinc and the copper—and it breaks readily; therefore heat the brass without actual contact with fire, and it can be bent into any shape; then to harden hammer it, roll it, or, if wire, draw through a plate, and it will become hard and springy. Copper wire is not injured by making it red hot—apparently at least—and is hardened again in the same way as brass—by pressure. Querist can easily make an experiment with a bit of wire heated in a candle flame, and then hammering it on a slab. S. R.

[97214.]—**Softening Brass.**—Heat to low red heat, and plunge in salt water. REGENT'S PARK.

[97214.]—**Softening Brass.**—Brass is softened by heating to a red heat, and cooling quickly in water, being just the opposite to that of steel. Brass is hardened by pressure, as passing through the rolls or hammering. To get the best results with spring brass, a special mixture of metals is used. For small quantities, careful hammering should answer. This is frequently done in the workshop if the metal happens to be soft, and is required hard. Wire is drawn through a hole smaller than the stock. WM. PROBERT.

[97214.]—**Softening Brass.**—Hard brass can be softened by heating until it turns a slight blue colour. It can be rehardened by compression, such as hammering or passing through rolls; the latter would be the method used for sheet brass such as you describe. T. J. LENEY.

[97215.] — **Hektograph Stains.**—Mixture of aquafortis and water, or oxalic acid and water, rubbing parts by means of cork, till colour is restored. Afterwards wash well with water, and dry and polish as usual. REGENT'S PARK.

[97219.]—**Rope Drive.** — For a small drive like this, if you wish to get satisfaction, I should advise you to throw out rope-drive altogether, and substitute a Dicks' belt. It will run equally silent, and, if first put on with a jump-joint fastener, then, after a month's run, it should be tightened, and an endless splice made, which Dicks's people will do very cheaply. You will then have a belt which will run for years without any further attention whatever. It will not stretch or slip, and is not affected by damp or heat appreciably. I have seen hundreds in use for some years, and know what a boon they are; and have also had considerable experience with rope-driver, using both endless system and multi-rope, and, except for very large driver, think it is greatly overrated, and, in many cases, belts would be preferable. With the single-rope system it is equally impossible to get tension on all strands alike, as with the multi, which you can easily see by watching sag of ropes while running. Use a three or four ply thickness of belt, certainly not more than four, and, if to transmit much power, increase width of belt instead of thickness. You will find it repay first cost in less than 12 months. Your pulley is far too small for satisfactory driving with ropes. MONTY.

[97219.]—**Rope Drive.**—In my query, p. 388, I meant to say the rope has to be very flexible, so I use cotton—not "collars," as it has been interpreted, probably owing to my indistinct calligraphy. What I want is a flexible but strong rope that will not continue stretching in use, as the cotton rope appears to do indefinitely.
Belfast. J. BROWN.

[97219.]—**Rope Drive.**—We should recommend you to have five separate ropes, as each rope would take up its share of the pull, and the tendency to stretch would be equally reduced.

WEBSTER MICHELSON AND CO.
Dudley. Electrical Engineers.

[97220.]—**Sizes of Wire.**—To MR. BOTTONE.—You cannot do better than procure Allsop's "Electric Light Fitting." S. BOTTONE.

[97223.]—**Staining Deal Cabinet.**—Remove varnish with some detergent. If necessary, stain, then polish. To as much yellow ochre as you can take in your hand, add half-teaspoonful Venetian red. Mix to thickness of paint, or rather thinner, with glue size. Simmer mixture for some time in pan, stirring well. Apply, when dry, sandpaper, and polish with French polish, or, if preferred, turpentine and beeswax. If deeper colour is required, add more Venetian red. REGENT'S PARK.

[97227.]—**Wimshurst.**—In reply to the question of "W. G. C.," may I first advise 12 plates, for he will then have the driving bands, and the brush holders uniform and a more symmetrical machine: (1) I prefer glass, it is better in many ways to ebonite; but it is very free to breakage. This latter is a consideration. (2) There is no advantage in making the driving pulleys of ebonite instead of wood. (3) Brushes made of fine gilt lace wire answer all purposes they last for a year or two, and the wire is only 6d. per ounce, or thereabouts. Get ½oz.—it will answer for three or four machines. (4 and 5). Tinfoil of the best and thickest quality is better than brass for the sectors—it lasts many years. The expansion and contraction of brass cause them to frequently break off the plates, no matter what cement is used. (6) Glass rod is best to support the collectors. (7) The machine never reverses under excitement. (8) Unless sectors are used, the machine is not self-exciting, except only when all is new. I have occasionally shown them at meetings many years ago; but they are most unsatisfactory. (9) Condensers are neither desirable nor necessary for X-ray work, except perhaps when the tube is very hard. (10) Get the archives of the Röntgen Society. (11) The secretary is F. H. Low, M.B., 12, Sinclair-gardens, West Kensington Park, W. J. W.

[97228.]—**Blue Printing.**—Potass. ferricyanide 2½oz., water 10oz., ammonio-citrate of iron (ferric salt) 2½oz., water 10oz. Two solutions dissolved separately and mixed, kept in the dark. Smooth surfaced paper is coated by means of a sponge, crossing strokes obliquely to get as even a coating as possible. As long as paper is actually covered, streakiness matters little. CLARA.

[97228.]—**Blue Printing.**—Ferricyanide potash, bichloride mercury, oxalic acid, iron and ammonium citrate, borax, nitrate silver, hydrochloric acid, iodide potassium, uranium nitrate, potassium oxalate, and potassium chloride. REGENT'S PARK.

[97228.]—**Blue Printing.**—A sensitising solution for these can be prepared as follows:—Citrate of iron and ammonium 44 grains, dissolve in water ½oz., then dissolve 35 grains of ferricyanide of potassium (red prussiate of potash) in another ½oz. of water. When the above are dissolved, mix the two solutions. This will form 1oz. only of solution; but, of course, you can increase the quantities by simple multiplication. Conduct all the operations by lamp light. On mixing the two solutions a precipitate will form, but there is no necessity to filter this off. Proceed to coat the paper, using a clean sponge or rag, and making the strokes in one direction, and afterwards crossing them in order to get a uniform coating. This will colour the paper a dirty brown, which will, however, rapidly change on drying to a greenish yellow. Allow the paper to dry, and when dry roll up and keep dark. It will be better for standing a day or two before using. To print, place the prepared surface in contact with the back of tracing to be copied in a printing frame to sunlight until detail is almost lost, which usually takes about five minutes in direct sunlight; remove from frame and wash in water face down until water ceases to be coloured green, usually three changes are sufficient. Use smooth faced paper, and, if possible, shrink it first, and see that the ferricyanide is of good quality. T. J. LENEY.

UNANSWERED QUERIES.

The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered, are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.

Expansion of Rails.—The following figures, relating to the expansion and contraction of railway rails, 30ft. long, but of different weights, have been obtained by actual experiment in America:—Contraction caused by change of temperature from 5° above zero to 20° below zero, 56lb. rail contracted $\frac{3}{16}$in., 75lb. rail $\frac{3}{16}$in., 85lb. rail $\frac{3}{16}$in.; expansion caused by change of temperature from 5° above zero to 70° above zero, 56lb. rail $\frac{1}{12}$in., 75lb. rail $\frac{1}{16}$in., and 85lb. rail $\frac{1}{17}$in. Several railroads in the United States are using rails 45ft. and 60ft. long. They have not, it appears, proved entirely satisfactory.

Coal in Canada.—The coal areas of Canada are estimated at 97,200 square miles, not including areas known, but as yet undeveloped, in the Far North. There are (1) the coalfields of Nova Scotia and New Brunswick, (2) those of the North-West Territories, (3) those of the Rocky Mountains, and (4) those of British Columbia. The coal areas of Novia Scotia cover about 635 square miles, and are divided into the Cape Breton, the Picton, and the Cumberland basins. The workable thickness of the coal is very great. In Cape Breton it ranges from 25ft. to 60ft., in Picton to at least 70ft., and in Cumberland at least 30ft. The fixed carbon averages from 58 to 60 per cent., volatile combustible matter 29 to 37 per cent., water 0·75 to 1·46 per cent., and ash 3·25 to 9·34 per cent.

Cost of Electrical Conductors.—A method for calculating the costs of electrical conductors made of copper, iron, or aluminium was recently given in *L'Industrie Electrique*. For a line of given length and resistance the weight of the conductor is proportional to the product of the specific resistance and the specific gravity of the material used. This product for iron is 78, for copper 14·24, and for pure aluminium 7·54. Thus we see that if aluminium costs about twice as much per pound as copper, the cost of the line will be the same for these two materials. The actual weight of a line will be $W = 0\ 000205 \frac{L^2 r S}{R}$, where W = weight in pounds, L = total length of wire in feet, r = specific resistance in microhms per cubic centimetre, S = specific gravity, and R = resistance of line in ohms.

QUERIES.

[97233.]—**Isle of Man Steamers.**—Will any kind reader oblige with particulars of the steamers *Duchess of Devonshire*, *Empress Queen*, and *Tynwald*, especially the first- engines, size, speed, pressure, &c.? as I spent a portion of holiday there, and boat-trips were very numerous. I should also be glad of the distances in miles from Douglas to Fleetwood and Liverpool and Ardrossan and Belfast, as we travelled in remarkably short time.—MANX VISITOR.

[97234.]—**Model Boiler Blow-Lamp.**—Will any reader give some idea or sketch, or refer me to a suitable blow-lamp burning benzoline for generating steam in a model boiler quickly? I find charcoal soon burns out, and methylated spirit is too weak.—AMATEUR.

[97235.]—**Melting Old Brass.**—Is it possible to melt old brass on a smithy fire for small model castings? Will it want anything mixed with it?—ANXIOUS.

[97236.]—**Chimes.**—Can any of "ours" inform me of the musical relation between the hour-bell and the chimes known as the Westminster chimes, and also the Cambridge chimes? I mean that supposing the Westminster chimes rang, say, in the key of G major, what is the correct note for the hour-bell. It seems that as G is the dominant of C major, C would be the note.—WESTMINSTER.

[97237.]—**Jewish Calendar.**—I should be glad if "F.R.A.S." would kindly answer the following queries: (1) What is the exact method of determining the commencement of the Jewish months? I find, from *Whitaker*, that it sometimes corresponds to the day of new moon, and sometimes to the day following. And this anomaly does not seem to be accounted for by the fact that the Jewish day commences at sunset. (2) Is it possible to determine on what day of the week new moon, or the 1st of Nisan, occurred in A.D. 31 (or was it 30?) the year of the Crucifixion? If so, we should then know on what day the eating of the Passover (14th of Nisan) occurred—whether it was on Thursday, the day preceding the Crucifixion, according to the first three Gospels, or on Friday, the day of the Crucifixion, according to the 4th Gospel. Or possibly it might be found that it occurred on some other day.?—STUDENS.

[97238.]—**Truing Emery Wheels.**—Can any reader supply instructions for truing up emery wheels in the lathe, and what kind of tool is used?—G. BOUSFIELD.

[97239.]—**Motor for Safety.**—Can any reader tell me what horse-power oil motor is required to drive a safety bicycle at 12 miles an hour, and which kind of motor and driving gear is most suitable?—G. BOUSFIELD.

[97240.]—**Invalid Carriage.**—Will someone give a sketch of an invalid carriage with side levers and crank, for invalid to work it himself?—S. REYNOLDS.

[97241.]—**To Mr. Bottone.**—I want to make a ½in. spark induction coil. Could you kindly tell me the length and diameter of iron core, size, and number of convolutions of primary wire and weight, and also weight of secondary wire and gauge, and number and dimensions of sheets of tinfoil for condenser, and would sheets of mica do instead of sheets of paraffined paper to separate the sheets? What battery power would produce the maximum spark?—G. EVANS.

[97242.]—**Plating Dynamo.**—I should be obliged if some reader would kindly tell me how to wind, and what size wire to put on, field-magnets and armature for nickel plating. It is a model Siemens pattern. The size of field-magnets and H armature are—field-magnets, 2in. by 2⅛in. winding space; armature groove, 2in. by ⅜in. by 5/16in. How much wire shall I require?—SECULARIST.

[97243.]—**Razors.**—I should feel extremely obliged if any of your numerous correspondents could tell me how, in a simple manner (if possible), to distinguish a hard razor from a soft one.—H. NEWTON.

[97244.]—**Grammaphone Experiment.**—I shall be much obliged if someone will help me out of this difficulty. I have been experimenting with a grammaphone, and have succeeded in taking the sound from both sides of the diaphragm at the same time, with a much louder result, as may be imagined. A little while ago I thought of using two diaphragms and two needles. This I did, and arranged the two diaphragms so that the needles were ½in. apart, getting an excellent result—in fact, twice the volume of sound. But what I want to know is this, Why do the two needles reproduce the sounds simultaneously? I can get the two needles very nearly 1in. apart (of course, in the same groove) before I can detect any "see-sawing" in the music or sounds. Of course, as there is double the weight on the sound-box arm, I have counterbalanced this with an extended arm and weight on the side away from the record.—LA VILCOQ.

[97245.]—**Horse-power for Car.**—What formulæ are there for finding the horse-power required to drive an electric car of a given weight on a given incline, and what would be the size of cable and trolley wire required? What would be the loss per cent. of theor. power derived from a waterfall transmitted to a car?—ANXIOUS.

[97246.]—**Air Heating.**—I am anxious to know if there is any formula or scale for determining the amount of heating surface necessary to heat air from 32° Fahr. to any temperature up to 500° Fahr.? For instance, how many feet super. would be required to maintain a temperature of 40° Fahr. in a room containing 3,000c.ft. when the outside temperature is 32°?—NEMO.

[97247.]—**Static Machines and X-Ray Work.**—Will someone kindly tell me (preferably "J. W.") as to (1) whether an eight-plate 24in. diameter Wimshurst can be worked by hand, and what length spark it would be likely to give? (2) I have a two-plate machine, which gives when forced an 8in. spark. What would be the right length tube exhaustion to procure? (3) In the machine mentioned which took a photograph of a thorax in four minutes and a half, what was the kind of machine, the length of spark and tube, and where could I procure a similar machine? (4) Is there any work written on this subject from a practical point of view?—SCALPEL.

[97248.]—**Compressed Gas as Motive Power.**—Can any correspondent give information upon compressed gas for motive power, and, if possible, give the address of any maker of small compressed gas-meters? I believe a car was designed for compressed gas, but I never heard with what result.—W. W. J.

[97249.]—**Vertical Boiler.**—What can be done to prevent corrosion of the inner plates of a vertical boiler which has to stand ten months in the year?—CHEMICUS.

[97250.]—**Phonograph.**—Will some correspondent oblige by reporting on the performance of the double diaphragm reproducer recently described in this journal?—SOUTH AFRICA.

[97251.]—**Parrot Cage.**—I have a parrot cage which I cannot use on account of a blackish grease rubbing off the wires on to the bird. This grease in the course of a week got all over the bird, so that I had to transfer it to another cage. If I rub a wire between my finger and thumb, I get a deposit something like lead. Can any reader suggest a remedy? The cage is an expensive one, but I do not know the maker's name. The bands bear a mark, "Mohr's Patent Indestructible."—SOUTH AFRICA.

[97252.]—**Telescope.**—A telescope has recently come into my possession, the object-glass of which is not cemented. When I cement it it will no longer focus. What is the reason, and the remedy, please? I do not think the o.g. is the original one, as a liner has been put in to reduce size of cell from 2⅝in. to 2⅜in.—SOUTH AFRICA.

[97253.]—**Crankshaft.**—I have a 3½in. cylinder, 5in. stroke. Would any kind reader tell me the diameter of crankshaft, crank-pin (overhung crank), piston-rod, and valve-spindle 80lb. pressure? Also rule for working out the same would be thankfully received.—ROBERT CRAWFORD.

[97254.]—**Covering for Bandsaw Pulley Rims.**—Can any reader give a good way of fastening leather on pulleys of bandsaw? The way I do at present is to get enough good leather to go round pulley and join end to end with cobbler's twine, then cover pulley with glue and spring leather on tight; when dry, pegging with wood pegs about 6in. apart on both sides of rim. But I find the leathers work loose after a few days' work.—SAWYER.

[97255.]—**Steam Turbine.**—Will any kind reader supply sketch of machinery of the above, as I wish to make one to drive small dynamo about ½H.P.? Also size of boiler and pressure required? Do they require very accurate making?—ANXIOUS.

[97256.]—**Windmills.**—Where can I get up-to-date information about windmills, &c.? Also, could any reader give instructions for making an instrument for accurately measuring wind-pressure and velocity?—ALTERNATOR.

[97257.]—**Coherer.**—Could any of our kind friends give details of construction of the latest and best form of coherer for wireless telegraphy? I should also be much obliged for any details of construction of a small alternator to give very high voltage for Tesla effects. Also for particulars of the latest form of the Wehnelt electrolytic current-break.—ALTERNATOR.

[97258.]—**Annealing.**—Will any of "ours" explain how to anneal small steel stampings and steel castings? I have tried charcoal, &c., in boxes and heated slow, but still some come out very hard.—R. W.

[97259.]—**Keeping Oil-Engine Cylinder Cool.**—I should be glad to know the best way of keeping oil-engine cylinder cool, without using water, for a 2H.P.? I want to save the trouble of taking water about with the motor. I want to use engine for motor-car. What I want is a superheated cylinder?—A CONSTANT READER.

[97260.]—**Electric Sparking Plug.**—Will anyone please say what is the most suitable cement to use for jointing the brass terminal and conducting wire to porcelain plug as fitted to the De Dion motor? Any information will oblige.—F. W. B.

[97261.]—**Pattern Making.**—Will some reader help me in the following matter? I wish to make several patterns to obtain malleable iron castings from, as I only want two or three of each kind. I do not want to go to more trouble than possible. I have had no experience at all in this matter, so wish to know if I can make the three following patterns solid, or shall I have to make them in sections? (1) Hub, same pattern as ordinary cycle-hub, only much larger; (2) pulley-wheel, with double flange on to keep belt from slipping off; (3) cap for screwing on to end of hub pattern, similar to shallow teacup. A reply to this will greatly oblige.—METAL TURNER.

[97262.]—**Frogs.**—Can anyone tell me what to feed green tree frogs on during winter?—M. FAKER.

[97263.]—**Organ Building.**—I read with much instruction the articles on above subject by Mr. Matthews in "Ours" some months ago. But as the stops I have at hand are somewhat different, would any reader give me some advice as to their allocation, and the smallest dimension of bellows that they will require to carry them on a 2in. wind? Would the following specification answer well?

Great Organ.

Open Diapason, 8ft (metal)	56 pipes.
Principal, 4ft. (metal)	56 „
Piccolo, 2ft. (metal)	56 „

Swell Organ.

Stopt Diapason 8ft. (wood)	56 pipes.
Flute, 4ft. (wood)	56 „
Gamba to Fid. G, 8ft. (metal)	37 „
Vox Angelica to Tenor C, 8ft. (metal)	44 „

Pedal.

Double Stopt Diapason, 8ft. (CCC to BBB).	12 „

—BACKFALL, Edinburgh.

[97264.]—**Glass Harmonicon.**—I should be glad if any of your readers could give me information as to how to construct one of these. I wish to know the greatest compass that can be used, the most suitable thickness of the glass, and whether there should be a constant proportion between the length and breadth of the strips. I think I should have no difficulty in fixing the strips, and only require information as to the glass portion of the instrument.—WYNFELL.

[97265.]—**Orion.**—Will "F.R.A.S." give me the R.A. and Declination of the three stars in Orion which are in a line? Also, can he recommend a cheap book on the position, magnitudes, and other remarks about the fixed stars, where I can obtain it, and the price?—ORION.

[97266.]—**Optical Lantern.**—I should be much obliged if any reader would give me information upon the construction of an optical lantern. Could I make one, and would it be essential to have a condenser and to get good results on the screen? Could I make the condenser myself? I am in an engineering shop, and go in for photography. Could I in any way make a rectilinear lens do instead of a special lens, or would it be essential to have a special lens for the purpose? I should be very grateful if I could get the information, and would be pleased if diagram were given.—C. W. C.

[97267.]—**Indelible Marking Ink.**—The recipes given some time ago for non-metallic marking inks have turned out failures, as they were anything but permanent or proof against washing. Could anyone furnish one to equal melanyl, jetoline, &c., or those adopted by shirt and collar makers, in durability?—JERSEY.

[97268.]—**Hektograph Ink.**—Would anyone kindly state how to prepare an ink, colour of it immaterial, to be used with the hektograph (slab of a mixture of seven parts glycerine and one gelatine), easily destroyable or removable? It is required for the printing of patterns for embroidery on materials of cotton, linen, wool, or silk. On the present occasion, the work concerned being all white, the application of chemicals to remove the ink would not be objected to, so long as the fibre of the material was not injured, though for more general use a suitable ink available in connection with coloured work, where, for instance, the stronger acids would be debarred, would be more valuable. Aniline inks are otherwise employed for hektographs, which would, however, not answer, as they seize the material, and cannot be destroyed. These afford, it is claimed, up to 150 copies; but half a dozen would be as much as would be ever needed in embroidery. Iodine, if it left better traces in printing, would do otherwise admirably, as even heavy iodine stains yield without trouble to a hot iron or ammonia.—JERSEY.

[97269.]—**Cloudy Lenses.**—I have a Leitz one-tenth and a Reichert one-twelfth which are useless, owing to the clouding of the lenses. Last year I sent them to their respective makers to be repolished, and they are now as bad as ever. Can any of our readers tell the cause, or if they can be cured by having new lenses put in where the faulty ones are?—J. J. CLARKE.

[97270.]—**American Organ.**—Can someone recommend me a good instruction book on the American organ, explaining the stops, &c., also telling something of its construction, if possible?—M.

[97271.]—**Motors.**—To "THE WRITER OF THE ARTICLES" or "MONTY."—Will you please inform me how I should set the taps on a De Dion latest tricycle when going down a hill, so as to save petrol? Up to the present I have simply switched off the current; but I presume I am using petrol at the same rate as if I was taking power from it. I have not had an opportunity of looking inside a carburettor, so I am unable to trace the connections of the regulating taps. I judge the left hand tap is for regulating the quantity of gas and air after being mixed, and now passing to cylinder, and I presume that the right hand tap will have another opening opposite to the one which is open to the atmosphere, so that if you take more air you are compelled to take less gas, and therefore reduce the richness. Is this so? Any hints on saving petrol will oblige.—F. W. B.

[97272.]—**Languages.**—I shall be glad if some of your readers will tell me of any books written for Englishmen on the Dutch, Danish, and Swedish languages?—W. H. MURGATROYD.

[97273.]—**Magnet.**—Can any reader tell me what size magnet (permanent) I should require to suspend a steel ball, 1in. in circumference, through a slab of ivory ½in. in thickness?—R. J. GOODMAN.

[97274.]—**Motor Cycle.**—Would the writer of the Motor Tricycle be kind enough to give me the following information regarding the motor? I am about to build a tricycle to your dimensions, but would prefer to have it 2¼H.P. I notice that certain firms are converting 1¾H.P. motors into 2¼. I presume that they will alter the diameter of cylinder and valves, the stroke being the same. Would you give me the necessary dimensions of alterations? Will it alter the dimensions of the tricycle at all?—OLD READER.

[97275.]—**Smoky Chimney.**—Can any readers recommend an alteration likely to cure a smoky chimney? It is a large, old chimney in a farmhouse, and smokes when the door is shut. When the door is kept open it is all right. I have tried putting what is called a louvre chimney-pot on the top, and when this proved useless, or worse, I tried closing it up at the bottom; but neither did this do any good. Perhaps some experts can help me?—AMATEUR.

[97276.]—**Boiler.**—I wish to make a water-tube boiler, the tubes to screw into a central hollow casting of aluminium bronze. Can anyone tell me if ⅛in. is thick enough, or unnecessarily thick, for the substance of casting? Also, what alloy of aluminium is the best? I want to work at 100lb. pressure.—B. E. S.

[97277.]—**Condenser.**—I am making a tube condenser in which the water is to circulate outside the tubes. Must there be a chamber at one end for the condensed steam to accumulate in? Where do I put the pipe connecting to air-pump? Could any reader who has time and inclination kindly give me a sketch of such condenser?—B. E. S.

[97278.]—**Force Pump.**—Whereabouts should the water from the condenser be pumped into the boiler at—above or below the water-level?—B. E. S.

[97279.]—**Harp-Playing.**—Is this as difficult to learn as the piano? What is the meaning of single and double action? Would a four-octave be a useful instrument for home use, or would a bass guitar be more useful, considering the difference in price?—HARPING FOR A HARP.

[97280.]—**Steam Pressure in Locomotives.**—Can any reader tell me what is the highest steam pressure carried by any locomotive running in this country? I mean, of course, the blow-off pressure to which the valves are set.—SELIM.

ANSWERS TO CORRESPONDENTS.

*** All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries, put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

*** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

CHRISTMAS WEEK.

The CHRISTMAS HOLIDAYS will practically necessitate our going to press with the number for Dec. 29 on SATURDAY, DEC. 23. The office will, of course, be open on Wednesday, Dec. 27, and advertisements and late communications will be taken up to the usual time of going to press on that day; but advertisers and others who want to make sure of their communications appearing in the issue of Dec. 29 had better see that they reach us on SATURDAY, DEC. 23.

The following are the initials, &c., of letters to hand up to Wednesday evening, Dec. 13, and unacknowledged elsewhere :—

JACK OF ALL TRADES.—John Bywater.—G. Dobbs.—Meteor.—W. T. N.—F. B.—T. Richards.—Try Again.—Hyde Park.—W. H. Daw.—F. Fitzpatrick.

W. INGRAM.—About 22 knots for the fastest—that is, the liners running to New York. The trip there takes, roughly, six days; to the Cape 14 days.

CELLULOID.—Have not heard of any complaints. It is more probable that the gold-plating is too thin.

PLANT.—The questions are for a professional man who understands such work, and will want to see the place before he advises as to the water-supply for a town, or even a village.

W. HALL.—Do not suppose there is any such class in existence in this country or elsewhere, as you seem to have discovered by inquiry at "neighbouring polytechnics." Such work as that is learned only by practice as an apprentice under skilled workers. You can find a great deal about French-polishing, enamelling, &c., in back volumes, which you can probably see in one of the free libraries.

B. BROWN.—Good starch paste is as good as anything, with a little alum or other preservative. The plates should be damped as well as the mount, and be stretched until dry on a proper mounting board.

HARPING FOR A HARP.—It is a matter of personal taste, and of the ability of the individual. The query is inserted, but do not be disappointed if a full answer is not forthcoming. Most of the dealers would answer the questions. Rather hard-tipped fingers are needed, or skin that does not easily peel.

FOR A PRESENT.—The average cost of carriage of our set of "Twenty-five Best Books" seldom exceeds two shillings anywhere in the three kingdoms. If you send us P.O.O. for £1 12s.—that is, 30s. for the books and bookcase complete, and 2s. for the carriage, we will despatch the set by rail to the address of any friend to whom you wish to make a Christmas or New Year present, packed in a thoroughly strong and well-made wooden case to insure arrival without damage.

J. A. SARGENT.—Lists of all important lectures for the forthcoming week are published in such periodicals, amongst others, as the *Journal* of the Society of Arts and the *Athenæum*. Many of the daily papers give a list under the head "To-Day," and some evening papers do the same under the head "To-Morrow."

W. N. BARBER.—The paragraph is of American origin, extracted from a report of experiments made either at Cornell University or Harvard. The experiments do not seem to have much to do with the steel used in watches.

E. G. WOODHOUSE.—Photo too small to be of any use. It is little use offering to give "full instructions" privately. When we insert queries, we want replies for the benefit of many—not one reader. Many good-natured correspondents seem to forget this.

J. R. F.—Cassell's publish a good cheap one, but at the bookstall at King's Cross or Euston on arrival you will find several on sale from 1s. upwards.

ON the basis of results of previous exhibitions at Paris, it is expected that 52,588,280 people will pass through the turnstiles, and it is thought possible that the total number may reach 60,000,000 in 1900.

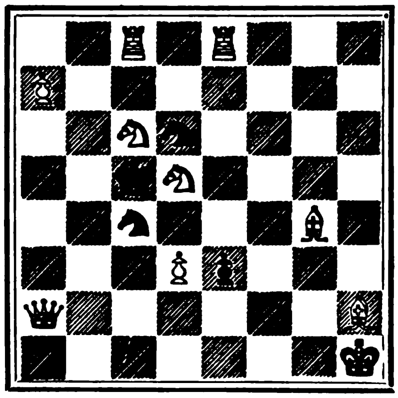
THERE are nearly 10,000 miles of railways now in operation or under construction in Africa. Already 1,400 miles of line northward from Cape Colony, and 1,100 miles southward from Cairo are complete, the intermediate distance being about 3,000 miles.

CHESS.

All communications for this column to be addressed to The CHESS EDITOR, at the Office, 332, Strand.

PROBLEM No. 1705.—By L. HAWKINS.

Black. [4 pieces.



White. [10 pieces.

White to play and mate in two moves.

(Solutions should reach us not later than Dec. 25.)

Solution of PROBLEM No. 1703.—By B. VALLE.

Key-move, R-B2.

NOTICES TO CORRESPONDENTS.

PROBLEM No. 1703.—Correct solution has been received from S. Woollen, Richard Inwards, J. E. Gore, A. Tupman, T. Clark, F. B. (Oldham).

REV. DR. QUILTER, H.J.B. F., A. M. M., W.-H.—Only solution as above.

FIELDTHWAITE.—Problem received with thanks.

MR. P. H. WILLIAMS, 36, Downshire-hill, Hampstead, writes that he is offering for one shilling his small collection of problems, and intends to devote the money received to the War Fund.

USEFUL AND SCIENTIFIC NOTES.

M. VALLOT, the director of the observatory on Mont Blanc, has been considering the advisability of installing the Marconi wireless telegraph system upon the mountain. The ordinary system is used normally, but the great snowdrifts have played havoc with the telegraph wires.

Natural History Stories.—While some men were digging some peat at Bottisham Lode, a village near Newmarket, they came upon a species of bog-oak about 100ft. long, some 8ft. below the surface. The men were in the act of splitting open the tree when they found in the centre a honeycomb in a perfect state of preservation. In various parts of the comb were bees. The entrance to the comb was through a big knot, and it is supposed when the tree fell the opening was downwards, and thus imprisoned the bees in the comb. The tree in course of time sank into the peat, and on to the gault, where it remained until found by the men.

MR. P. H. BAGENAL, the Poor-Law Inspector for the Eastern Counties, in presenting his annual report, describes East Anglia as "the home of octogenarians and nonagenarians." He has ascertained the average age of the ten oldest paupers in each workhouse. The Norfolk ancients showed an average age of 84, Essex 86, Suffolk 84, and Wisbech 89. In the Essex workhouses there were 23 inmates of the age of 90 and upwards; in Suffolk 13, in Norfolk 31, in Wisbech Union 4; total 71. In Norwich Workhouse one inmate was 100 years old; in Henstead one was 99; and in Rochford one was 98; while in Chelmsford, Tendring, King's Lynn, and Thingoe there was one each aged 97 years.

TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

5s. 6d. for Six Months and 11s. for Twelve Months, post free to any part of the United Kingdom. For the United States, 13s., or 3dol. 25c. gold; to France or Belgium, 13s. or 16f. 50c.; to India, New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-Office Order. Back numbers can also be sent out by the ordinary newspaper post at the rate of 3d. each.

Vols. XXIV., XXX., XXXII., XXXVI., XXXIX., XL., XLII., XLIII., XLIV., XLV., XLVI., XLVIII., L., LI., LII., LIII., LIV., LV., LVI., LVII., LVIII., LIX., LX., LXI., LXII., LXIII., LXIV., LXV., LXVI., LXVII., and LXVIII., bound in cloth, 7s. each. Post free, 7s. 7d.

Indexes to Vol. LI., and to subsequent Vols., except Vols. LIII., LV., LVI., LVII., LIX., LXI., 3d. each, or post free 3½d. Cases for binding 1s. 6d. each.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each post free from the office (except Index numbers, which are 3d. each, or post free 3½d.)

NOTICE TO SUBSCRIBERS.

Home Subscribers receiving their copies direct from the Office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a PINK Wrapper, as an intimation that a fresh remittance is necessary if it is desired to continue their subscription.

Foreign Subscribers will have the Pink Wrapper sent ONE MONTH before expiration, in order to give them time to forward fresh remittance before subscription expires.

ADVERTISEMENT CHARGES.

The Charge for Advertisements in the Columns headed :—

For Exchange.
For Sale.
Wanted.
Addresses.
Situations.

is Sixpence for the first Sixteen Words, and Sixpence for every succeeding Eight or part of Eight, which must be prepaid. *No* reduction on repeated insertions. Advertisers should state under which heading they wish their announcements to appear.

The address is included as part of the Advertisement and charged for. No displayed Advertisements can appear in above columns. Rates for Displayed Advertisements are as follows :—

For advertisements on inside pages, except page facing leader, for less than a quarter-page; per inch single column—

1	6	13	26	52	insertions
7s. 0d. ..	6s. 6d. ..	6s. 0d. ..	5s. 6d. ..	5s. 0d.	each.

Per Column.—

1	6	13	26	52	insertions
£3 0s. ..	£2 15s. ..	£2 10s. ..	£2 5s. ..	£2 0s.	each.

	1	6	13	26	52	insertions.
	£ s.	£ s.	£ s.	£ s.	£ s.	
Per Page....	8 8 ..	7 0 ..	6 0 ..	5 5 ..	5 0	each.
Half-page ..	4 10 ..	3 15 ..	3 10 ..	3 0 ..	2 10	,,
Quarter-page	2 10 ..	2 5 ..	2 0 ..	1 15 ..	1 10	,,

Back Page, £10 10s. A few dates open during 1899.

ORDINARY ADVERTISEMENTS.

	£ s.
Thirty Words	2 6
Every Additional Eight Words	0 6

Front Page, Five-Shillings for the first 40 words, afterwards 6d. per line. Displayed Advertisements, 10s. 6d. per inch. Paragraph Advertisements, One Shilling per line. No Front Page or Paragraph Advertisement inserted for less than Five Shillings.

All Advertisements must be prepaid, and in cases where the amount sent exceeds One Shilling, the Publisher would be grateful if a P.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.'s.

Advertisements *must* reach the Office by 1 p.m. on Wednesday to insure insertion in the following Friday's number.

For the convenience of advertisers, replies to advertisements (except those in the Exchange and Sale Columns) may be addressed to "———," care of the ENGLISH MECHANIC Office, and will be forwarded by post to the advertiser, for an extra fee of Sixpence per insertion over and above the cost of the advertisement.

All Cheques and Post-Office Orders to be made payable to THE STRAND NEWSPAPER COMPANY, LIMITED, and all communications respecting Advertisements should be distinctly addressed to :—

THE PUBLISHER,
THE "ENGLISH MECHANIC,"
332, STRAND, LONDON, W.C.

This is necessary, as there are several papers published at the same address, and unless letters are fully directed, it is impossible to tell for which paper they are intended.

For Exchange.

The charge for Advertisements in this column is 6d. for the first 16 words, and 6d. every succeeding Eight, which must be prepaid.

SPECIAL NOTICE. — *Correspondents are strongly recommended not to send money or goods to strangers. The safest way when dealing with unknown advertisers is to send a Post Office Order made payable —— days after date, when in case of non-arrival of goods, or dissatisfaction, payment can be stopped.*

The English Mechanic
AND WORLD OF SCIENCE AND ART.

FRIDAY, DECEMBER 22, 1899.

MAKING A SPIRAL DRUM.

SPIRAL, or screw drums or barrels, are made by the crane firms by casting and by cutting. The cost of the cutting is unnecessary, except in some of the higher-speeded drums for wire ropes. There are many large barrels in which the cost of cutting would be prohibitive. Some of the largest of these, as used on Titan cranes, are 8ft. and 9ft. diameter. Many scores of drums, ranging from these dimensions downwards, and of all sections, have been made under the writer's superintendence, the larger in loam, the smaller moulded in greensand from loam patterns, swept up by boards. This article will relate to the latter only.

Fig. 1 illustrates one of the simplest forms of crane barrels, such as occur in diameters of from 1ft. 6in. to 2ft. 6in. Not until a diameter of about 3ft. is exceeded are these swept up in loam.

The section shown is that in which the chain links lie alternately flat and edgewise. When they lie diagonally, the grooves are shallow. When wire rope is used, the grooves are shallow, and closer together. Each form alike is swept up by the devices illustrated in these figures, to which the explanations to follow apply. Fig. 1 is as plain as a drum can be made. The shaft bosses are chiefly internal. There is no lug for the chain, which is screwed with a strap to the outside of the barrel.

Fig. 2 shows a sectional illustration of the loam pattern at a certain stage of the work, and a plan view of the striking board, by which it is swept. The general rig-up will be recognised readily. A A are the iron trestles (compare with Fig. 4) in which the bar B revolves, and upon which the striking-board C rests. This board carries two others, D and E (Figs. 2-4), the first used for roughing up, the second for finishing the loam pattern.

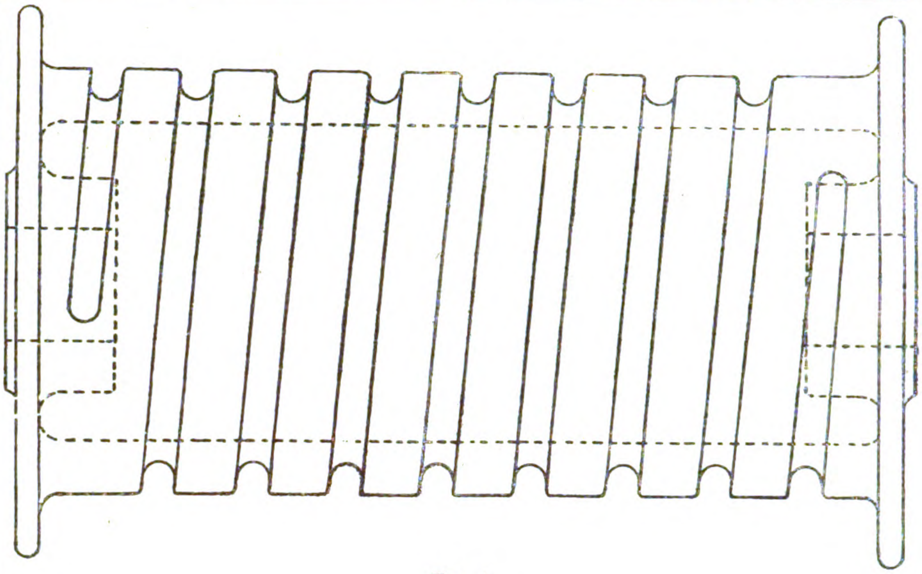


FIG. 1.

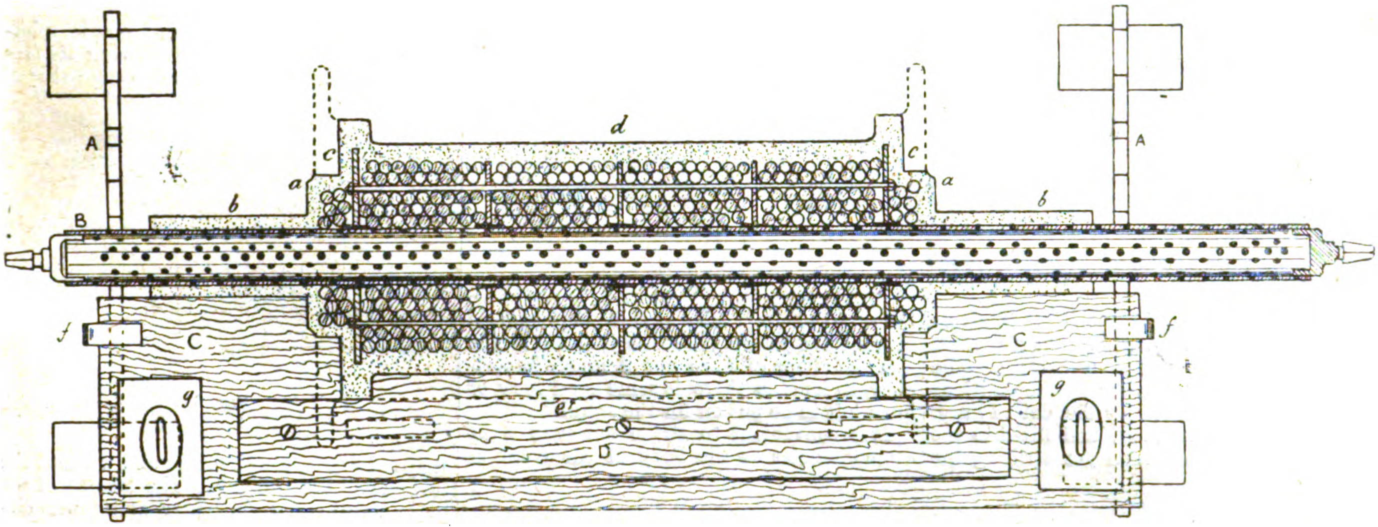

FIG. 2.

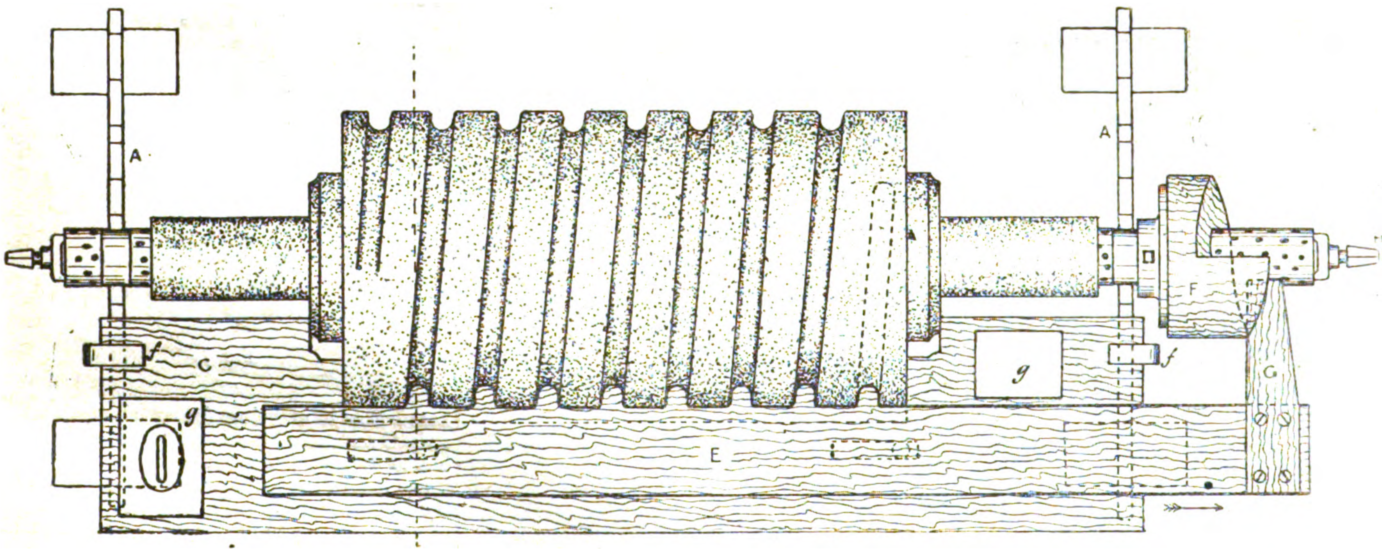

FIG. 3.

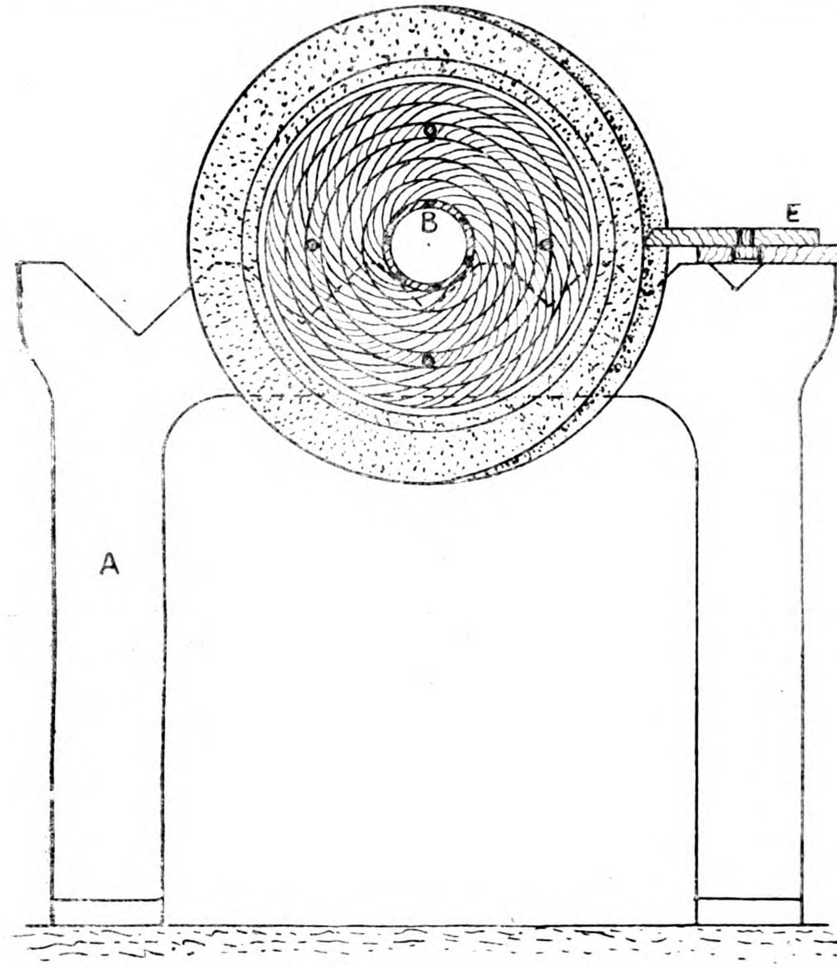

Fig. 4.

The first board C (Fig. 2) is used to strike the end bosses *a a*, the prints *b b*, the shoulders *c c*, and a false foundation body *d*. The shoulders *c* receive the flanges, the positions of which are indicated by the dotted lines. These are turned in wood, and fitted to the loam pattern. The reason for striking the the roughed-up pattern at this stage is dried in the stove before the screw is struck. The size and shape of *d* are not of much importance, so long as there is some good body of loam left to be put on for the spiral.

It is convenient to strike the ends of the same diameter as the body of the drum, as

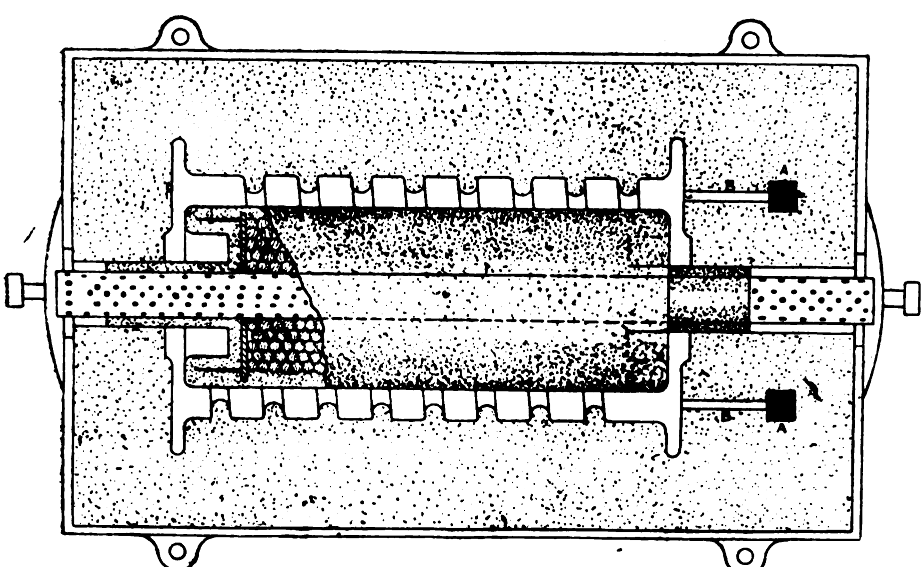

Fig. 8.

portion *d* smaller in diameter than the drum is to have a body dry and hard preparatory to the striking up of the screw. If the screw were swept up at the same time as the soft body, it would, in consequence of the mass of the latter, sag and go out of truth in drying. The board D therefore is used to sweep the body to the section of *d*, after which shown, and this affords a guide for the correct setting of the second board E. The edge *e* of board C does nothing, board D alone striking the body *d*. Board D is screwed to C.

The loam pattern, seen in plan section in Fig. 2, and in cross section in Fig. 4, is swept up on a core-bar, with plates, and hay-bands, in the manner shown. The plates are wedged on the bar at intervals, and secured with through-bolts after the bands have been wound round as far as the circle of the bolts. This makes a firm body which may be easily moulded from a score of times; *f f* and *g g* are clips and weights by which the board C is secured on the trestles A A.

The next stage of the work is seen in

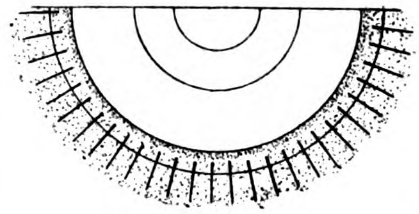

Fig. 5.

Figs. 3 and 4. Here the board D has been unscrewed, and its place taken by board E, which has studs attached to its underside, to move in slot-holes of a length equal to the pitch of the spiral on the drum. Board C has been drawn back from the body, so that no rubbing takes place excepting that of E, which alone is in operation. In the figure, the board E has been slid over C to a distance nearly equal to the pitch, and the screw is shown complete all except the length seen dotted to the right.

The method of striking is by a templet-screw, F. This is of wood, having its face cut to pitch by means of wedge-shaped

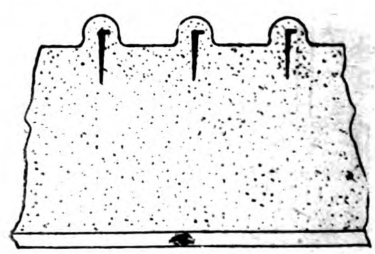

Fig. 6.

strips of paper, glued within and without the turned and bored blank. The lengths of the paper strips equal the outer and inner circumferences of the blank, and they taper from a width equal to the pitch of the screw at one end to nothing at the other. The hypotenuse gives the edges for cutting the faces of F by. It is screwed to an iron boss-plate, which is pinched upon the bar B with three set-screws. On the board E a strip G is screwed, the inner face of which bears against the spiral face of the templet. A boy or man turns a winch-handle at H, while the core-maker or pattern-maker attends to the

Fig. 7.

board E as it is being drawn along by the strip G and templet-screw F. This operation has to be repeated from a dozen to twenty times before the loam-screw is finished. At the termination of each traverse the rotation of the work has to be checked and the board slid back: otherwise the tongues on E would tear up the loam. The groove formed in the loam by the sliding back of the board, and which is equal in thickness to the board, is filled up after the striking is finished. This portion is rubbed correctly when dried. Often a little rubbing and finishing have to be done at the termination of the screw-threads

after the loam has been dried. Finally, the body is coated while hot from the stove with tar, and varnished, the wooden flanges put in place, and the composite pattern moulded, as in ordinary work in greensand.

In moulding drums with deep grooves like this, the sand which forms the grooves would fracture unless supported well with nails, Figs. 5 and 6. Fig. 5 is a section through a groove, and Fig. 6 a view in the joint face, showing the nails *in situ*. The edges in the joint break up, chiefly in the cope, which is lifted from the pattern. A mending-up piece like Fig. 7 is employed to make broken edges good.

Fig. 8 is a plan view of the bottom half of the mould with the body core in place. The left-hand end of the core is broken away, to show the method of carrying the annulus of sand around the internal boss, long prods being cast on the end-plates for that purpose.

The pouring of these drums is from one end. In Fig. 8, A A are the ingates and B B the runners. A A come down through tho cope, B B are either in the joint face of the drag, as shown, or lower down in the mould. They are narrow and deep, and the metal runs along between the core and the grooves without beating against either.

Many barrels have right- and left-handed grooves for chain or rope, distributing the load between two coils. These are swept up by two boards—that is, board E in Fig. 3 would be duplicated. One would strike from left to right, as in the figure, the other from right to left. Then another templet-screw like F, but of the other hand, is required, and this is fastened upon the left-hand end of the bar. This is one particular case only of the many varieties of spiral drums which arise in practice. The large drums made in loam and struck with one or with two screws, and often having internal bosses, smaller cores, and so forth, give much more trouble. Fusee drums, too, for derricks are cast with grooves, and many other variations occur which call for special treatment. Some of these may, perhaps, engage our attention on a future occasion.

J. H.

ORNAMENTAL TURNING.—XXXIII.

By J. H. EVANS.

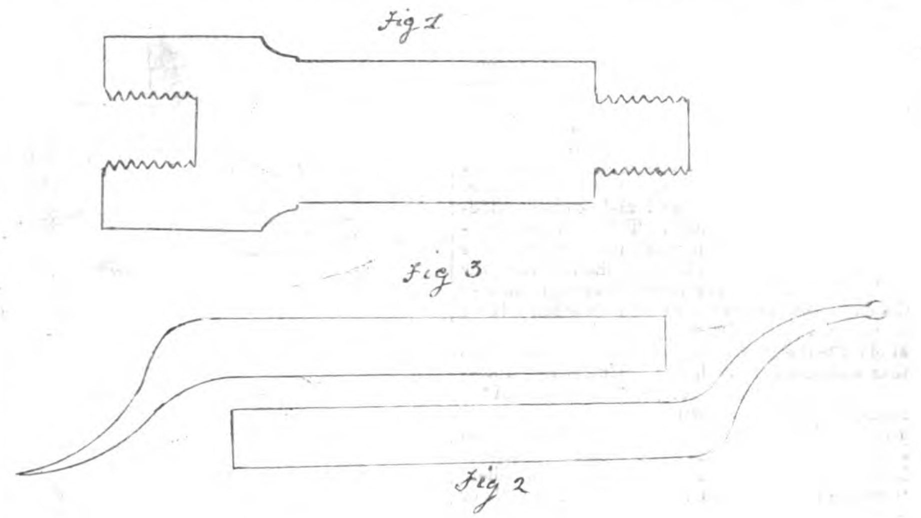
HAVING previously completed the necessary details in connection with the manufacture of the spherical slide-rest, we come now to the necessary tools, beyond those used with the ornamental slide-rest, that will be required, to be followed by a descriptive view of the general manipulation of the rest, for simple and complex works, and these will, I think, be better and more readily grasped if worked in together. By this I mean as we come to a point in the details of manipulation requiring a certain tool it will be there illustrated and described.

The difficulty of producing an accurate sphere by plain hand turning, and ultimately decorating the same, or curves of a kindred nature, by continuous ornamentation, may be said to have been the means of the simple rest of this character, which I stated in my first on the subject, as known to Bergeron, to the present state of perfection, and rendered it one of the most valuable additions to the ornamental turning lathe of the present period.

In its present state the spherical slide-rest is capable of many consecutive movements, by which means convex and concave curves of almost any degree are readily obtained from a small bead around the periphery of work of large dimensions to a complete sphere of from 3in. to 5in. in diameter; and when so turned the bare form may be decorated to an unlimited extent by the substitution of revolving cutters for the fixed tools originally employed.

The curves thus produced, whether concave or convex, and their position, depend entirely upon two conditions: first, the placing of the worm-wheel by aid of the lower slides; secondly, whether the cuting edge of the tool be adjusted to the far or near side of the axis of the worm-wheel.

I will here give as clearly as possible the best



means of making a zero, by which a line marked upon the first slide will enable the operator to place the worm-wheel under the axis of the lathe. The proceeding will be as follows:—Turn a cylinder, then mark on it a fine pencil line, place the slide-rest on the lathe, with the axis of the worm-wheel as nearly as possible under the pencil-line, place the fourth slide parallel with the third by means of its index and division on the ring surrounding the socket of fourth slide, and both parallel to the first slide. Now place a double-angle tool, one of those usually employed in the ornamental slide-rest, in the tool-box, and, by means of the second slide, bring its point exactly opposite the pencil-line. The tangent screw may now be thrown out of gear, and the worm-wheel turned precisely half-way round, and, by means of the first slide, it is so adjusted that the tool shall just touch the line, both on the far and near sides of the cylinder. The axis of the worm-wheel will then be found to be exactly under that of the lathe. This satisfactorily accomplished, a fine but distinct line should be marked across the face of the first slide. The zero—so to speak—being once thus defined, the

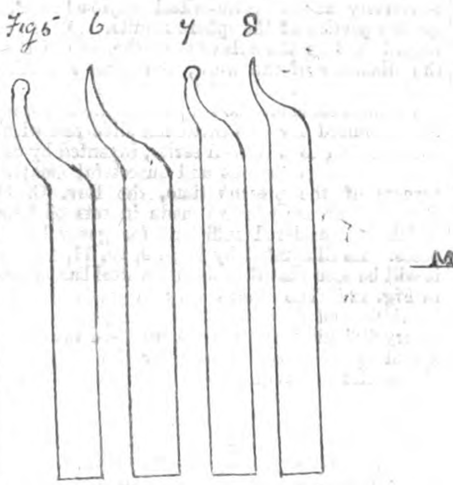


FIG. 4.

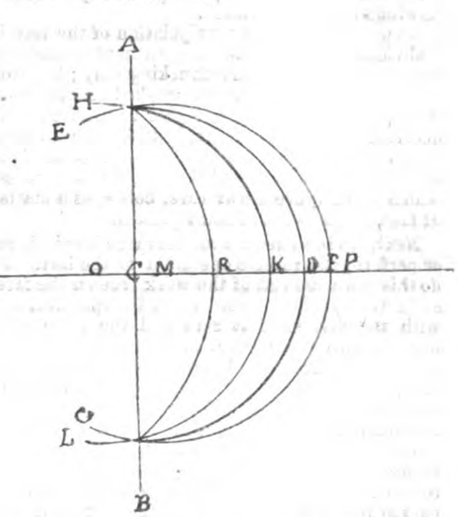


worm-wheel can always be readjusted, which will be found sufficient for all practical purposes; in fact, it is all that can be desired, and the presence of it will greatly assist in the future setting of the rest for many purposes.

So far, then, we have before us the means of placing the worm-wheel accurately in a transverse direction. It will, of course, be equally necessary to effect a similar adjustment in the reverse or longitudinal plane. This will be obtained by the following means:—Place the third slide parallel with the second, and then move the slide-rest until a straight edge, placed and held closely against the face of the work, coincides precisely with the zero line which passes transversely through the axis of the worm-wheel.

By the two settings thus explained we have arrived at the method to adopt in thus placing the slide-rest; but I propose to go much further, and endeavour to more fully detail the many ways of manipulating the rest. As a primary illustration, let it be desired to cut a boxwood sphere. I recommend boxwood, as that material is quite good enough for trial purposes. We will take it to be, say, 2in. in diameter. First turn the wood to a true cylinder of the required size, and perfectly true and flat at the end. This done, mark a pencil-line exactly 1in. from the end. We now have a guide to lead us in the right direction, and may proceed to remove the superfluous material by hand-turning, and thus reduce approximately to the desired shape—viz., a sphere. When executing this part, care must be taken not to remove the pencil-line, as we shall require that, as will be seen. We next place the slide-rest on the lathe with the axis of the wormwheel, exactly under the pencil-line, and the first or lower slide must be adjusted with equal precision to the zero marked across the base, which was fully explained in my last.

These two slides, so far set, must not be again moved. Any other alteration may be made as you please, which will probably only interfere with the dimensions of the work in hand. We come now to the tool to be employed. If one of the ordinary short slide-rest tools be used, it will be found that during the semi-revolution of the wheel carrying the fourth slide, the latter will come in contact with the shoulder of the work, unless reduced below the diameter of the work; or, if the chuck should be short, the slide will then be stayed in its progress by the mandrel-frame itself.

I have found it a considerable help over this little difficulty—if it may be so termed—to have an elongated chuck about 4in. in length with a nose on the extremity, to correspond, of course, with that of the mandrel. This is illustrated in Fig. 1, and should always be available, although it is not always necessary. The inconveniences arising from this cause leads up to the intro-

duction of curved tools. Of these there should be several sizes. It is true that with a curved tool that would travel round a sphere of, say, 4in. diameter, would be available for one of half the dimensions; but it will be equally evident that a tool suitable for a 2in. circle would be useless as applied to a sphere of larger size.

By referring to Figs. 2 and 3, the particular kind of tool which is most suitable will be seen. These are made to fit the tool-box of the slide-rest, and are $\frac{5}{16}$ in width. This is for the purpose of strength, as they are generally used for work of increased diameter, and the nature of the tools which it will be seen receives the pressure of the cut at a distance from the main stem. If we study these for a moment, the object of the two kinds illustrated will become evident. Fig. 2 is that which is first used, and having a round nose cutting edge of more strength, may be termed the roughing-out tool, notwithstanding a smooth cut may be taken over the work. Fig. 3, it will be seen, is brought to a sharp front, and acts more or less as a parting tool, as it will sever the sphere from the material it is made of, leaving little or nothing to be removed.

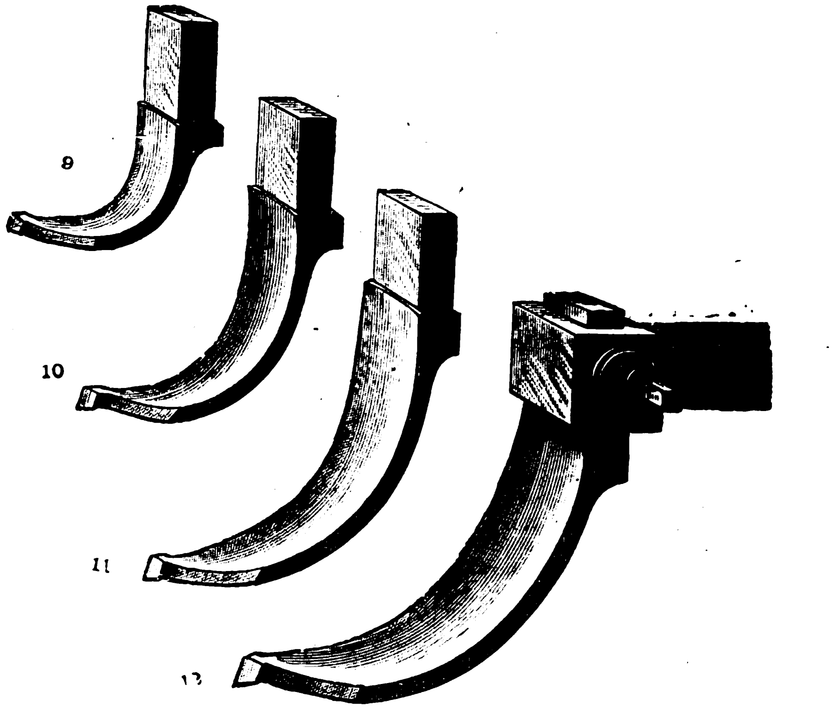
Assuming that a plane sphere only is required, it will be obvious that when severed, even by a tool as described, be the point ever so sharp, it must leave something attached to the ball when it falls, and to remove this without destroying the exact features of the sphere is a difficult and somewhat dangerous process. It must be re-chucked, and the safest plan to adopt is to re-adjust the spherical rest to remove the superfluous material, or it may be attempted by hand-turning if the operator is sufficiently expert and confident to trust to it; but it must not be forgotten that should the least portion too much be removed, we no longer have a sphere, but practically a mis-shapen object of little or no use. I refer to this as illustrating the very great care required to effect the desired object.

These tools are generally made in sets of either six different sizes or ten, to turn from a 1in. to 4in. sphere. Then we have another set made to the same size in the stem as those usually made for the ornamental slide-rest—*vide* pp. 5, 6, 7, and 8. These for small work are extremely useful, being less cumbersome, and altogether more suitable. We have now before us the most improved tools for the purposes of spherical turning as explained. There is, I may say, nothing more to be said with regard to the manufacture of these; the illustrations tell their own tale, except that good sound forgings must be procured.

To proceed with the manipulation of the rest, it obviously impossible to ornament a sphere entirely from pole to pole by one chucking only; but this can be effected by a line marked exactly upon the equator, and when one side or hemisphere is decorated, it can be rechucked the reverse way, with the equatorial line perfectly true with the surface of the chuck. This, however, is a process which will require great care, being, as a matter of fact, a somewhat difficult process.

Next, let it be desired to excavate a hemisphere, or perform the reverse operation to the last. To do this, turn the end of the work true on the face, as in the previous case. Place the spherical rest with the first slide at zero and the third slide parallel with the second, so that the zero line of the worm-wheel shall precisely coincide with surface of the work. This is effected by means of the second slide. Thus: Commence with a straight tool with a round nose, which must be inserted gradually, while it sweeps out the material as the excavation progresses. When the fourth slide comes in contact with the edge of the work, a curved tool must be employed (the particular kind will be referred to later on), and the hemisphere completed. Of course in practice the bulk of the material would be removed by hand-turning, and the hemisphere only finished by.

In furtherance of our object I have prepared a diagram, Fig. 4, illustrating the curves: though simple, it will be found, I hope, very useful. Its explanation is as follows: Let M P represent the axis of the lathe from mandrel to poppet-head, C the centre of the work, and A B the diameter and back of the work. (1) With tool set at radius C B, and worm-wheel coincident with C, the hemisphere A D B results, and any alteration of the radius would only increase or decrease it; (2) if the worm-wheel be ·25 nearer P at M, the curve E F G results; (3) if the worm-wheel be ·25 nearer M at O, the curve H K L results. It will be observed that these curves E F G, H K L, must fall within the diameter A B; therefore this must be compensated by an increase of radius if the



diameter A B is to be preserved. And, again, this increase of radius will necessitate another compensation, E G, if the hemisphere A D B has been cut, and it is desired to cut a curve, A K B, passing through the point A B, and also through K, a point ·25 nearer to M; then by means of the second slide the worm-wheel must be moved from C to O—i.e., ·25 nearer to M; but curve A K B falls within the point A B by, say, ·05 nearer, therefore the radius must be increased by ·05; but this will bring the curve ·05 further from M beyond the point K, consequently the worm-wheel must be moved nearer to M by fully ·05, for as the worm-wheel is moved towards M, so does the curve A K B fall still further within the points A B. (4) It is obvious that as the worm-wheel approaches M the flatter does the curve become, as A R B, provided that by increased radius the tool slide travels through A B, and conversely as the worm-wheel approaches P, a greater portion of the sphere results. (5) If you regard A B as the axis of the lathe, and M P as the diameter of the work, the same reasoning applies to oblate and prolate speroids.

I cannot conclude the subject of the necessary tools required for this particular slide-rest without referring to a special series, invented by one of our most prominent and successful amateur turners of the present time, the Rev. C. C. Ellison. These tools are made in sets of four, which is considered sufficient for general purposes. As illustrated by Figs. 9, 10, 11, and 12, it will be seen that they fit into a steel bar, shown in Fig. 12. The blades vary in form, ·8 to 1·5 in width, and though simple in appearance, are a very difficult tool to make, and are turned by a tool specially constructed for the purpose, to the precise radius of the curve they are intended to cut—viz., 2, 3, 4, and 5in. diameters. By using these tools little difficulty is experienced in removing the whole of the inside of a hemisphere, either of soft wood or ivory, the same being turned out in shells, clean and true to shape, and, so far, ready to be chucked and ornamented without further labour. There not only is a vast amount of labour saved, but a deal of valuable material, which in the case of ivory is a great consideration. Having said so much, I will point out the manner in which they are used.

We will suppose that we have to operate on a solid block of ivory. First turn the face true, and mark four circles of 2, 3, 4, and 5in. in diameter; place the tool-box of the spherical slide-rest level with the front of the fourth slide, and fix it by both depth and stop screw, both being thus employed for security, and to stay vibrations. Now place the steel bar quite home in the tool-box, adjust the rest to excavate a 2in. hemisphere, using the blade made for this purpose, Fig. 9; care must be taken to place the blade quite home in the bar.

Next throw the tangent screw out of gear, release the fixing screw of the socket ring, and adjust the edge of the blade to touch the 2in. circle already marked on the ivory, and the inside of the blade to a trifle less than 1in. from the centre of the face of the material. These positions are more easily made by a brass gauge made for the purpose.

To continue, place the tangent-screw as gear, and secure it by the fixing-screw; the tool may now be passed into the ivory, by slowly rotating the tangent-screw, and a solid hemisphere will be cut out. The same operation is repeated with the various blades when hemispheres of those particular sizes are required. Should the blade have to be removed for the purpose of sharpening, it must be replaced with the greatest accuracy. Now in using these tools, there is one very important thing to notice, without which some difficulty may arise, especially when operating on work of large diameters. It is this: while the blades can be made of almost any strength, the spherical slide-rest, from its construction, is comparatively unstable. In order to counteract the great strain in cutting a large diameter, it is a great assistance to place a piece of soft wood against the face of the work, and between the bottom of the back and the top of the third slide; this prevents vibration, and eases off the strain upon the rest. Should it be desired to cut out shells greater or less than a hemisphere, the axis of the worm-wheel must be moved further from or nearer to the lathe-head.

I think I may claim now to have said all that is to be said with respect to the manufacture of this all-important addition to the ornamental turning lathe, also with reference to the manipulations, and I propose to conclude the subject of the spherical slide-rest in my next, illustrating therein a finished specimen of work that I executed with it from base to summit, accompanied with the necessary details for its reproduction, if it is considered worthy of reproduction.

MILLWRIGHT'S WORK.—XXI.

FIG. 132 illustrates a diagonal drive by the Webster Co., in which a 16ft. eleven-grooved pulley, A, drives B, 7ft. diameter, 96ft. away, measured in a horizontal plane. The idler C has eleven grooves, and a loose sheave for the rope to the tension-pulley D. The leaving one pulley-groove loose was a method adopted at Belfast many years ago. This is a 500H.P. transmission with 1½in. rope.

A curious transmission is shown in Fig. 133. Two driving sheaves at A transmit power in the same direction to the pulley B on one floor, and in the reverse direction to the pulley C on the floor above. One sheave at A has five grooves to drive to B, the other six to drive to C. D has twelve grooves. One groove sheave is loose at D, to drive to the tension E, and one sheave on B is loose, to drive to the tension F.

Fig. 134 shows a section through a rope-drum and its loose sheave; the latter, being narrow, is

fitted with a specially long hub. Fig. 135 illustrates a drive from a twelve-grooved pulley, A, 8ft. in diameter, to one B, 5ft. 8in. diameter,

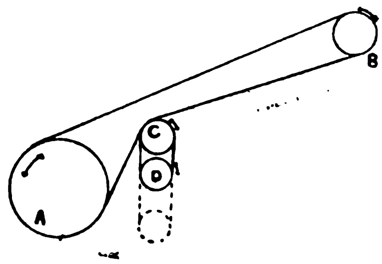


FIG. 132.

situated at 24ft. centres, measured in the horizontal plane. C is an idler with twelve grooves and a loose one, the latter driving to the tension-pulley D, with 15ft. of travel.

For the average length of rope, about two per cent. of the total length of the rope is allowed for tension. The Webster Manufacturing Co. adopt the rule that a single tension cannot, under any

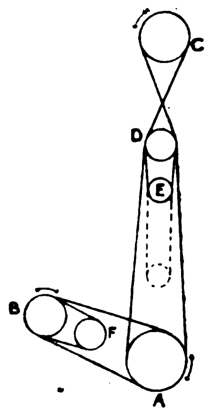

FIG. 133.

circumstances, take up the slack on more than twelve grooves, and then the ropes must run slowly, so that double and treble tensions often have to be adopted. The maximum length of rope for a single tension should not exceed 3,500ft. The tension should take the slack rope from the driving sheaves and loose grooves, as

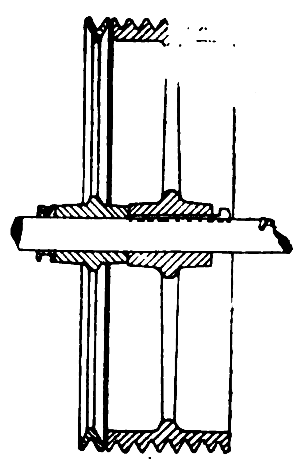

FIG. 134.

previously noted, and must be used in idler-pulleys, which should also be on the slack side.

The tension-pulleys are mounted in a good many ways. Figs. 136 and 137 illustrate two types only: one for horizontal, the other for vertical arrangements.

The idler-pulleys are used to guide ropes in desired directions, to prevent swaying, and to relieve bearings of strain. In English practice sectional forms of grooves have been frequently given to idlers, different from those which are used on driving pulleys. This practice is not much adopted in America, where grooves are kept standard, excepting in regard to depth.

The great value of ropes for twisted drives is on a par with their utility in the transmission of power from the main shaft of the prime mover

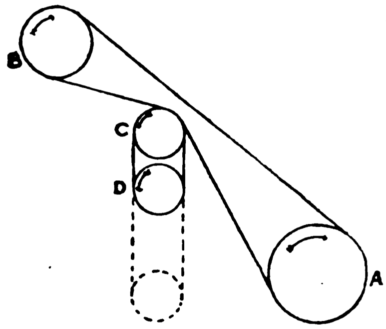

FIG. 135.

to distinct lengths of shafting, driving machinery on separate floors. Belting is ill-suited for this service, because the conditions are unfavourable, the reasons of which are

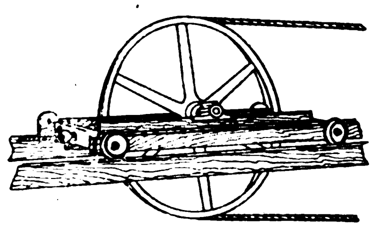

FIG. 136.

apparent from a consideration of the limitations to belt-driving which have been already stated. In fact, belt-driving is so inefficient under such conditions that toothed gearing has

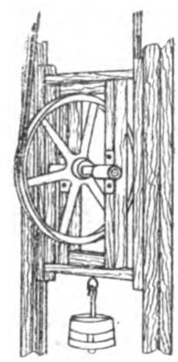

FIG. 137.

been largely used instead. But spur and bevel gears and heavy shafts are not ideal forms of transmission. They are heavy, and generally intolerably noisy if employed to any great extent.

An illustration of the multiple driving system in a large mill is given in Fig. 138. This represents a section of a mill fitted by Hick, Har-

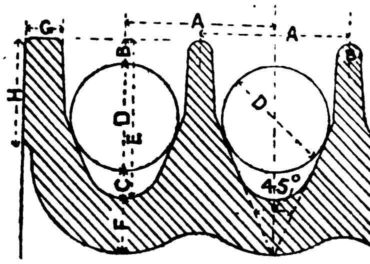

FIG. 139.

greaves, and Co., of Bolton. A broad flywheel A, on the crank-shaft of the engine, has enough grooves turned on its circumference to carry all the ropes required to drive the main shafts throughout the mill. It fulfils the same purpose as the compound driving previously illustrated,

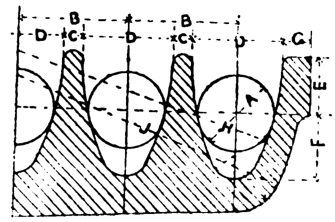

FIG. 140.

only instead of superimposed belts the ropes lead off in successive adjacent sets. In Fig. 138 the flywheel A is grooved for thirty-five ropes. These pass off to the various pulleys on the different floors in sets of four, five, seven, &c. Each rope is independent of the others in this, the "multiple" system. The most remote shafts, therefore,

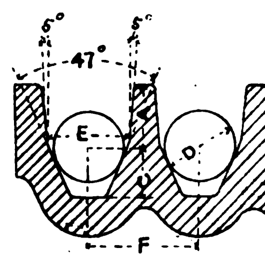

FIG. 141.

are driven directly from the one big driving flywheel instead of through intermediate shafts and gears. Such prolonged transmission would be impracticable with heavy belting.

Extremely long rope drives are also sometimes taken through the open from one building to

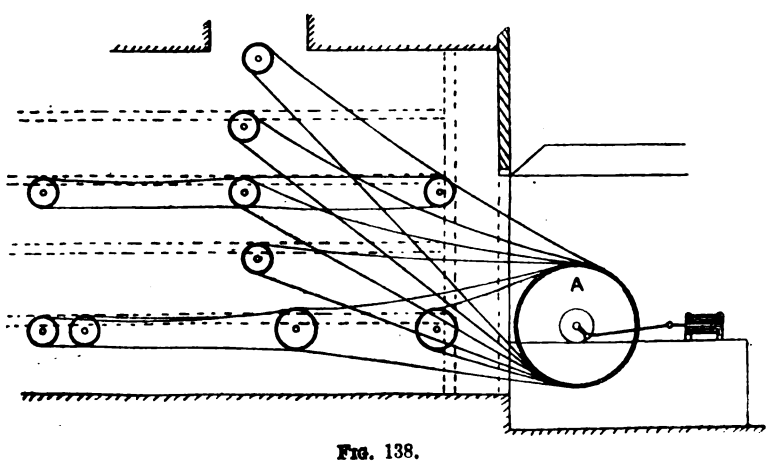

FIG. 138.

As the lesser evil, they have been often preferred to belting. But with the introduction of rope-driving much of this gearing has been taken out, and with advantage.

another. This could not be done with leather belting, and although the canvas beltings will stand weather, they are still open to the other objection to the use of belts for very long drives.

The advantage of the driving of shafts at different angles by means of ropes somewhat resembles their driving by the wedge-shaped leather link belting. Both are highly flexible, and each unit of width takes its fair share of the

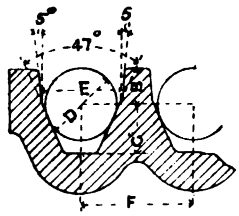

FIG. 142.

work. The single ropes are equivalent to a belt cut up into several strips, each lying closely to its work, which a solid wide leather belt cannot do when the drive is not parallel.

Not much diversity of opinion exists in reference to the angles of the sides of the pulley grooves: 45° was settled many years ago at Belfast. The principal variations are illustrated below.

Fig. 139 illustrates common English practice, and the formulæ give proportions for various sizes of ropes.

D = diameter of rope.
A = $1\frac{1}{4}$ D + $\frac{1}{4}$in.
B = $\frac{1}{8}$ D + $\frac{3}{16}$in.
C = $\frac{1}{4}$ D
E = $1\frac{3}{8}$ D + $\frac{3}{16}$in.
F = $\frac{1}{2}$ D + $\frac{1}{16}$in.
G = $\frac{1}{4}$ D + $\frac{3}{16}$in.
H = D

Fig. 140 is by the Walker Manufacturing Co., of Cleveland, and the table gives dimensions.

DIAMETER OF ROPE:—

A	B	C	D	E	F	G	H	J
in.	in.	in.	in.	in.	in.	in.	in.	in.
1	$1\frac{1}{2}$	$\frac{1}{4}$	$1\frac{1}{4}$	$\frac{3}{4}$	$\frac{7}{8}$	$\frac{3}{8}$	$3\frac{13}{32}$	$3\frac{3}{4}$
$1\frac{1}{4}$	$1\frac{3}{4}$	$\frac{5}{16}$	$1\frac{7}{16}$	$\frac{15}{16}$	$1\frac{1}{8}$	$\frac{1}{2}$	$4\frac{11}{32}$	$4\frac{11}{16}$
$1\frac{1}{2}$	$2\frac{1}{8}$	$\frac{3}{8}$	$1\frac{3}{4}$	$1\frac{1}{8}$	$1\frac{5}{16}$	$\frac{9}{16}$	$5\frac{13}{64}$	$5\frac{5}{8}$
$1\frac{3}{4}$	$2\frac{1}{2}$	$\frac{7}{16}$	$2\frac{1}{16}$	$1\frac{5}{16}$	$1\frac{1}{2}$	$\frac{5}{8}$	$6\frac{1}{16}$	$6\frac{9}{16}$
2	$2\frac{7}{8}$	$\frac{1}{2}$	$2\frac{3}{8}$	$1\frac{1}{2}$	$1\frac{3}{4}$	$\frac{3}{4}$	$6\frac{15}{16}$	$7\frac{1}{2}$

The C. W. Hunt Co., of New York, adopt an angle of 47° for the sides of the pulley grooves

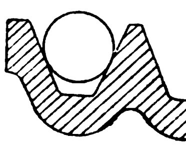

FIG. 143.

for rope driving. The forms designed for deep, medium, and shallow groves are shown in Figs. 141, 142, and 143 with their formula:—

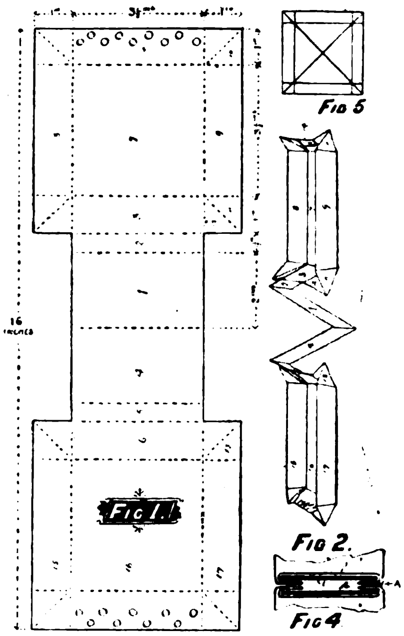
D = diameter of the rope.
A = D − $\frac{1}{8}$in.
B = ·5 D
C = ·7 D
E = D + $\frac{1}{4}$in.
F = 1·375 D + $\frac{3}{8}$in.

These grooves have an advantage over those with concave profiles. They are more easily turned, and easily measured. J. H.

AN AUTOMATIC ROCKER.

THE advantages attached to the automatic rocker that will be described in this article are, chiefly, three:—(1) The simplicity of construction. (2) The cheapness of materials necessary. (3) There is no soldering whatever to be done, and this, to the amateur who has never tried his hand at soldering before, is no mean consideration. The rocker is made out of one piece of material, with no joints of any description. The size of this material, of course, depends entirely upon the size of the rocker required.

The dimensions given in Fig. 1 are those required in the construction of a washing apparatus for lantern slides. The reader will find no difficulty in working out the proper dimensions for larger or smaller size tanks. A sheet of zinc or tinned iron—preferably zinc—is taken and cut to the size and shape given in Fig. 1. The holes are best formed with a twist-drill, but if this method cannot be pursued, they must be punched from the face side of the material. This will prevent any possibility of prints being rubbed against the birr made by punching the



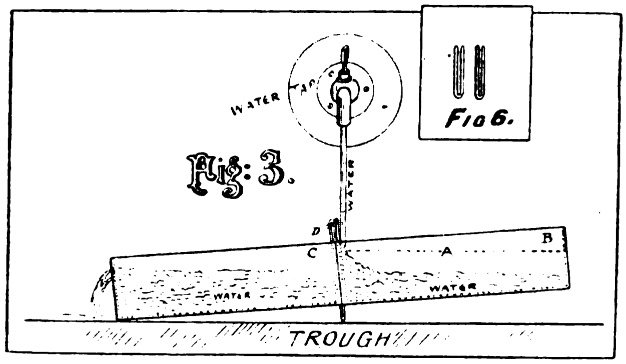
holes. When the material has been cut to the proper shape it is bent up at the dotted lines to form Fig. 2. To understand exactly how the corners are bent up the reader is advised to adopt the following plan:—Take a square piece of stiff paper, and crease in the manner shown in Fig. 5. Then, when the sides are bent up in the form of a dish, it will be seen how easily and naturally the corners fold round. In exactly the same manner must the corners of the metal be bent up, with the aid of a pair of pliers.

It will be seen in the diagrams that the numbers correspond in both Fig. 1 and 2. If this is carefully followed out, no difficulty whatever will be experienced. The four extreme corners of the apparatus are then folded round to the sides of the two dishes. They must not be folded round to the ends, as the holes would then be partially blocked.

The strip 1 (Fig. 2) is then pressed close to the dish nearest it, and the corner piece 11, folded round over it. The same is done with the strip 4, and then both the strips 1 and 4 are pressed closely together. This will bring the dishes in close contact with each other. Two small wire staples (Fig. 6) are then thrust in either side of the middle portion—i.e., referring to Fig. 2, one into the spaces between 1 and 11 and 4 and 13, and the other in the opposite side.

Fig. 4 represents a sectional plan of this middle portion, with the position of one of the staples indicated by the dotted line at A. These staples serve to keep the two vessels together by preventing 1 and 4 (Fig. 2) from spreading open again. When this has been done, the apparatus should be enamelled black on the outside and white on the inside. It is obvious that if this rocker is placed underneath a tap, as in Fig. 3, the water will increase in B by inflowing, as it decreases in C by overflowing, and vice versâ after it has been overbalanced. By this method a continuous flow of fresh water is kept up in both compartments, and the plates or prints, as the case may be, receive a thorough washing. The dotted line A in Fig. 3 represents the level of the water in B, just as it is on the point of overbalancing. By carefully following out the instructions given, a very efficient "automatic rocker" can easily be made.

Theodore Brown.



THROUGH A SMALL TELESCOPE.—II.

By NORMAN LATTEY.

OBSERVATONS of the sun should be conducted with the greatest caution. In no case should the eye be put to the eyepiece unless the dark cap (generally supplied with every astronomical telescope) has been first carefully screwed on. Focussing is best done on the bright edge or

FIG. 1.—Great Sunspot Group, March 25, 1894.

"limb." The whole surface can then be searched for any spot or other signs of approaching activity that may be visible. The most insignificant spot may in a few days develop into a gulf which could comfortably contain all the planets rolled into one. Every speck should therefore be carefully watched.

A low power—about 60—will just admit of the entire solar disc being inclosed in the field of view. The most noticeable feature that will at once attract attention is the curious shading towards the limb, due to the absorptive effects of the sun's atmosphere, which consists of a comparatively shallow envelope composed of glowing hydrogen and other gases, in which float fiery clouds of intensely-heated metallic vapours. Against this darkened background can frequently be seen irregular groups of scintillating faculæ, those strangely luminous streaks that often flicker around the borders of sunspots, or gleam softly in districts where they are about to appear. The exact meaning of these glistening manifestations is unknown; but they are generally assumed to be scudding at much higher levels than the apparent surface of the solar globe.

Ordinarily, the first signs of the impending storm and formation of a sunspot is a tiny speck on the lustrous surface. Within a few hours its growth becomes strikingly perceptible, and by the next day it not only often attains considerable proportions, but is commonly surrounded by clusters of diminutive spots almost imperceptibly gravitating towards each other. If the disturbance be sufficiently energetic, the torn and perforated area ultimately melts into a single yawning cavity of intense blackness called the umbra, which is generally surrounded by a lighter margin styled the penumbra. Within the umbra is occasionally seen a still darker centre termed the nucleus; but the last phenomenon is rather rare. As a rule, the umbra is bridged across by shreds of shining matter, evidently situated much above the gloomy

depths they appear to span. In all probability they consist merely of isolated fragments of faculæ hovering over the vortex of the tempest.

Frequently the larger spots endure sufficiently long to survive a complete solar rotation of 25 days—i.e., they appear at the eastern limb 12½ days after their disappearance over the western edge; but how altered! To give some notion of the rapid and total metamorphosis which these mysterious appearances undergo, three sketches are reproduced from the writer's observing book of the famous group of March, 1894. All the drawings were made at the instrument—a 2¾in. refractor. In Fig. 2 the splitting of the narrow

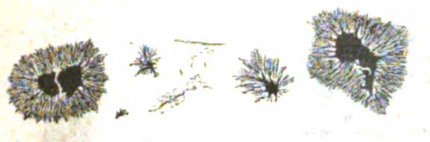


Fig. 2.—The Same Group Twenty-Four Hours After.

end of the pear-shaped umbra of the right-hand formation, and the complete change exhibited by its companion since the previous day, are both well illustrated, besides the fusion into one opening of the most extensive of the broken patches in the chain of perforations stretching between the "spots," and obviously indicating a sub-surface connection of some kind.

Five days later another sketch was made of the same group, which by that time had considerably extended, fresh rifts and openings having broken out in all directions. It would occupy too much

Fig. 3.—Another View Five Days Later.

space to here portray the entire area of commotion; but from Fig. 3 it will be noticed that the original twin formations are now hardly recognisable, the brilliant filament across the black umbra of the left-hand spot having entirely disappeared. The shape of the spot itself had also undergone a change, and the small adjacent spot which was isolated in Fig. 2 had become absorbed in the fringing border of the greater one. The tearing of the right-hand spot had also proceeded apace, the vast fissure now being twice its former length. Across it were shot forth three shining tendrils, one of which had reached to the opposite "bank." Along the same edge could be detected several more contemplating similar movements.

As stated at the beginning, observing the sun should never be ventured on until the dark cap is over the eyepiece. Any neglect of this precaution would almost certainly result in the destruction of the sight of the observer's eye. With the sun-cap—a deep smoke colour for preference—he is comparatively safe, provided the aperture does not exceed 3in. or 4in. Even then the telescope should be turned away from the glowing disc at intervals of a few minutes to allow the eyepiece and cap to cool. For apertures of more than 4in., a solar diagonal is absolutely necessary if direct vision is to be employed. By means of this contrivance the major portion of the light and heat rays gathered by the object glass is allowed to pass harmlessly down the eye-tube, but an intercepting "flat" of clear glass, or a prism, sends a subdued reflection to the eye through a tube placed at right angles. The image thus yielded is sufficiently bright for all practical purposes, and is, of course, perfectly cool and free from all danger. The simplest of these arrangements costs about 25s., yet even then the use of a pale sunshade of coloured glass is desirable. To those who can afford them they are strongly recommended, but for those who are not disposed to go to the expense the following description of a projection apparatus is given (see Fig. 4). It possesses the double advantage of being absolutely safe while permitting the solar image to be viewed by several persons at the same moment. It in fact turns the telescope into a miniature magic lantern.

Get a tinsmith to make a flanged collar of stout tin or brass with three small holes bored in the rim for screws. The collar must be a tight fit on the eye-tube, yet capable of both rotating and sliding up and down. To the face of the flange screw a piece of cigar-box or fret-wood 4in. square, with a hole in its centre to allow the eye-tube to pass through. Having prepared another piece of similar wood 8in. square (but, of course, without the hole), to receive the screen, connect them together with four strips, 1in. wide, ⅛in. thick, and 12in. to 14in. long. Paste thick black paper round three sides of the framework, and the narrower half of the fourth side. The apparatus is then complete.

To use it take out the eye-tube from the telescope, and pass it through the collar as shown in sketch. Then reinsert the eye-tube in the telescope, and pin down with drawing-pins on to the inner side of the larger square of wood a piece of the smoothest pressed Bristol board you can get. This will act as the screen. All that now remains to be done is to turn the telescope on to the face of the sun, and focus. Sliding the whole thing up and down the eye-tube—and, of course, the magnifying power of the eyepiece—will determine the size of the image. With a low power, say 40 diameters, and the framework drawn out to its fullest extent, the entire disc of the sun will easily come within the limits of the arrangement, which can be made any size and length.

It will be advisable to shut off all direct sunlight by either thrusting the object-glass end of the telescope through a pair of heavy window-curtains, should the sun be conveniently situated; or, if the observations are being made in the open air, by passing a fairly large piece of black card over the main tube of the instrument in order that the projection apparatus shall be as much as possible in shadow. By this means much interesting—even valuable—work can be done, and any astronomical society (if you belong to one) will be glad to have your sketches; or you might send them to the correspondence column of this paper for the benefit of fellow observers.

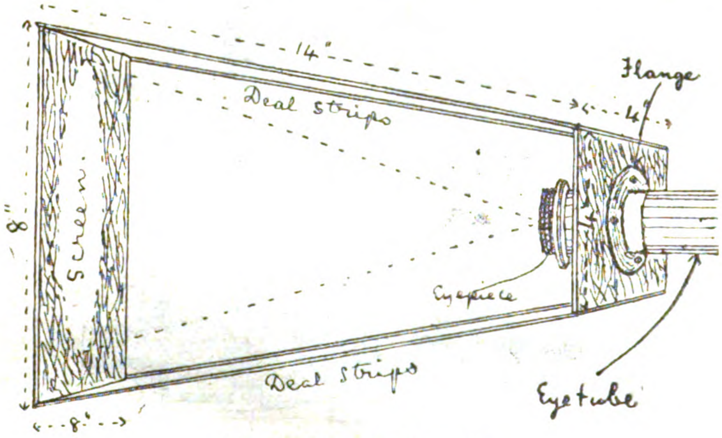

Fig. 4.—Projection Apparatus.

There are 112 towns in France outside of Paris which are provided with telephone exchanges.

PROF. W. R. SMITH ON DIPHTHERIA.

In the second of the Harben Lectures at the Royal College of Physicians, Prof. W. R. Smith, discussing the terms "infection" and "contagion," pointed out that formerly infectious diseases were considered to be those caused by certain poisons either entering the body from without or manufactured from within. To the latter the term "contagion" was applied, to the former a "miasma" was ascribed, the one arising within, the other outside, the diseased organism. In the present day only such diseases were considered infective as were produced by a living organism entering the body from without and capable of multiplication within. A diseased caused by a substance not capable of multiplication within was spoken of as an "intoxicative" process. In such infective diseases as diphtheria and anthrax there was a combination of these two causes—the mechanical presence of a specific organism and the metabolic products of the life of such. The difference between infection and intoxication, therefore, was that in the one the effects were immediate, while in the second there was an incubation period during which the poison was manufactured. In diphtheria the period was short—as a rule, not exceeding two or three days. Turning to the etiology of the disease, the lecturer alluded to an interesting fact, that the two sexes at the same age period were differently affected. In the first year of life boys were much more liable than girls to die of the disease; but this extra liability diminished year by year, and in the third or fourth year was transferred to the female side. Again, with regard to the incidence of diphtheria on children of various ages in London (apart from mortality) an examination of the figures for 1892-98 showed that the greatest attack rate was generally at the age of four to five; the rates were nearly equal for the three years of age, three to four, four to five, and five to six, while on each side of this three-year period they fell considerably. Infants under one year were remarkably exempt, and, if the notification returns might be trusted, liability to diphtheria was three times as great among children between one and two years old, and four times as great among those between two and three years old, as among infants in their first year. Direct infection from person to person was probably by far the most common cause of the disease. Milk was undoubtedly a vehicle of diphtheria, but whether the disease was transmitted by the cow through the milk or whether the latter was in all cases accidentally infected was a question by no means satisfactorily solved. The disease did not appear to have any direct relation to defective sanitary conditions, though these might lower the general power of resistance and give rise to throat complaints providing a favourable soil for the bacillus. Dr. Newsholme had suggested a relationship between the rainfall and outbreaks, but of all conditions exerting an influence on the spread of the disease that of school attendance was supposed by many to be by far the most powerful and far-reaching. This point was examined by the lecturer at considerable length. He mentioned that the medical officers of a large number of cities and towns, both in this country and in the Continent and America, whose opinions he had sought, considered that, on the whole, there was no important casual relation between schools and diphtheria. Dealing particularly with the figures for London, he found strong evidence that age-susceptibility was the main factor in the selection of the victims, and that, at the most, school-aggregation acted only as a slightly disturbing element. It was a fact that a child became more liable to be attacked year by year as it approached school-age, and less liable year by year after it had reached it. No special increase of liability could be traced to the beginning of school attendance, and there was nothing like constancy in the relationship of school holidays and a decrease in the notifications of diphtheria.

ALCOHOL INCANDESCENT LAMPS.

The success which has attended the introduction of the Auer incandescent mantle in connection with lighting by gas has led to various attempts to utilise the same principle with other heating media, especially with petroleum, alcohol, and various combined fluids. This matter formed the subject of a paper before the Société des Ingénieurs Civils de France by M. Denayrouze, who has himself contributed extensively to the improvements which have been made in lighting by incandescence, both in connection with gas and with liquid hydrocarbons.

It is well understood that the illuminating power of gas is entirely due to the incandescence of particles of carbon, and the wastefulness of this mode of lighting may be realised when it is understood, according to Saint-Claire Deville, that the hydrocarbons which form the illuminating portion of ordinary gas constitute but from 3 to 6 per cent. of the total volume, while the remaining portion is capable by its combustion of raising a much larger

mass to incandescence than is provided by the hydrocarbons present. It is its great richness in readily decomposed hydrocarbons which renders acetylene of such high illuminating power, while the introduction of an incandescent mantle composed of rare earths, as in the Auer burner, shows how great an advance may be made with ordinary gas.

It was a natural step to attempt to place such mantles over burners fed with liquid fuel, and in Germany various designs have been made, using methylated spirit, and even petroleum. Difficulties of various kinds were encountered, however, the principal one being an insufficient admixture of air to produce the high temperature necessary, and most of the devices are still in the experimental stage.

M. Denayrouze exhibited before the Société, however, a lamp containing the results of his latest researches, which seems to show that the difficulties have been surmounted in a practical manner.

An ordinary Welsbach mantle can be heated to incandescence over an alcohol burner, and thus be made to emit a brilliant light, but the cost is higher than desirable, and the illuminating power limited. M. Denayrouze has taken this idea, and supplemented it by charging the alcohol with hydrocarbons in solution to such an extent that the carbon in the flame and deposited upon the mantle also becomes incandescent, and adds greatly to the light without causing any increased consumption of alcohol.

While M. Denayrouze exhibited his lamps freely before the society, he did not give any very precise details as to the nature and quantity of the dissolved hydrocarbons which he used to reinforce the illuminating power of the mantle. The idea, however, is readily intelligible, and there should be little trouble in reproducing his results, now that the matter has been made public. The effect of the carburetted alcohol is clearly shown by the fact that when burned in specially designed lamps a very brilliant light is produced without the use of any mantle whatever, so that the combination of the two sources of light, especially when assisted by a slight blast of air, gives remarkable results.

The field of investigation which has thus been opened should lead to an active study and to the development of sources of illumination hitherto little used, and while electric lighting and incandescent gas-lighting will probably hold the larger portion of the field between them for a long while to come, yet for portable lighting, such as railway carriages, and similar service, some system such as offered by M. Denayrouze may be found decidely preferable.—*Engineering Magazine.*

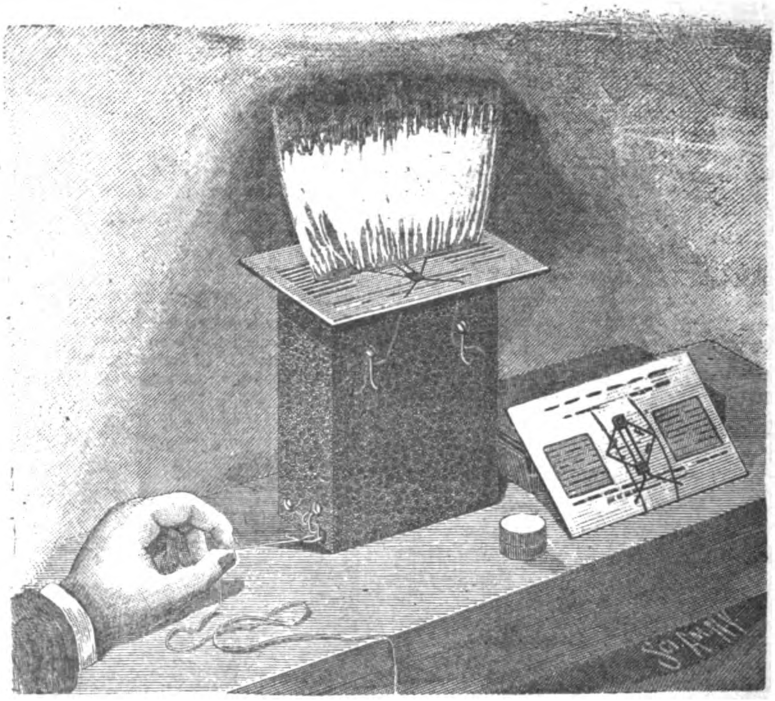
AN ELECTRIC FLASH-LIGHT DEVICE.

VARIOUS forms of lamps and devices for igniting flash-light magnesium compounds intended for photographic purposes have been invented during the past few years, several of which have been constructed in such a way as to promote the element of safety, for it is well known the setting off of a flash-powder is accompanied with more or less danger, and usually more than ordinary care is required.

The object of the electric flash-lamp shown in the accompanying engraving is to provide a perfectly safe lamp and one that is also effective, convenient to operate, and light to carry about.

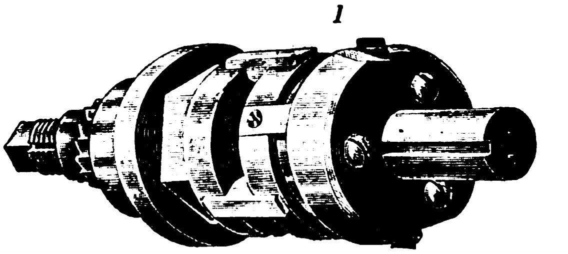
It consists of two cells of a powerful dry battery inclosed in a box suitably connected up in circuit, one part of the circuit being connected to two screws with spring fingers attached, as will be observed on the broad side, and similar screws at the bottom, at the narrow end. From one screw is a light spring wire, having a loop in its end, to which a spring is attached. From the other screw projects a hook-shaped shorter rigid wire. When the spring wire is pulled forward by the string, it brings both terminals into electrical contact. To the right of the box is a flash-card, having two fine wires on the surface arranged in a diamond form, and having in their circuit a minute platinum fuse. The card is placed on the box, and the wire terminals are slipped under the two spring wires, which completes the electrical circuit. The flash-powder, in a small, round box, is poured out on the card in the diamond-shaped space in such a way that some of it comes in contact with the platinum fuse. To ignite the powder it is only necessary to close the electrical circuit by pulling lightly on the string, which brings the two wire terminals at the bottom into contact, causing the electric current to heat the platinum fuse to redness and instantly fire the powder. The operation is extremely simply, and enables one to remain at some distance from the flash, and even to be included in the picture, as it is evident that the length of the string can be adjusted to suit the circumstances.

With a light of this kind it is any easy matter to take instantaneous interior daylight photographs of children and infants. Placing them near a window, e camera is adjusted on a stand and focussed. The flash-light may be located 6ft. or 8ft. from the subject, arranged to illuminate the shadow side of the face. The shutter of the camera may be set a very slow speed. Taking the operating bulb of the camera in one hand and the string of the flash-lamp in the other, the photographer can set off both at the same time, compressing the shutter bulb with the right and pulling the string with the left hand. The intensity of the shadow side may be varied by the distance of the light from the subject. Very soft and pleasing children's portraits may be made in this way. But flash-light pictures at night can be made perfectly, and in large rooms duplicate sets of light can be arranged to flash at once and thereby give proper illumination. The device has also the merit of being inexpensive, which will commend it to many. We are informed that Himmer and Potter, of No. 163, Greenwich-street, New York, are the manufacturers of this convenient article.—*Scientific American.*

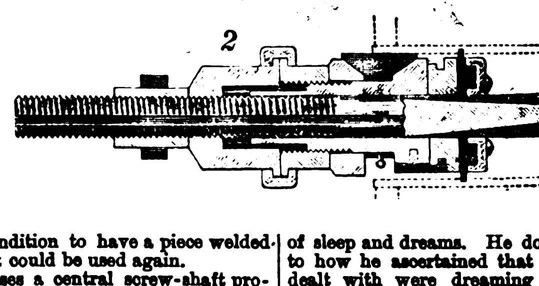


KRUGER'S FLUE-CUTTER.

THE flue-cutter which we illustrate in perspective and section was invented by Mr. Philip J. Kruger, of Greenville, Ill., to fill a want for a device by means of which a flue could be cut at the inner side of the sheet without forming a burr, thus leaving the flue in perfect condition to have a piece welded on the end, so that it could be used again.



1



2

The cutter comprises a central screw-shaft provided with inclined channels to receive the ribs of the cutter-carrying head. Owing to this arrangement the cutter-head is free to rotate with the shaft, and the shaft has longitudinal movement through the head. Cutters carried by the head are adapted to be moved outward by a longitudinal movement of the shaft and inward by a spring. The shaft is mounted to rotate in a sleeve on which clamping-blocks are supported by a spring ring. On the sleeve a ring is mounted for forcing the blocks outward, which ring is in turn forced longitudinally by a nut engaging a feed nut on the shaft. The abutting portions of both units are engaged by a locking collar. A second sleeve removably engaging the shaft, but rotating therewith, has ratchet-teeth on its outer side, which may engaged by a suitable tool to turn the shaft. This second sleeve brings the torsional strain upon the shaft nearer the cutters than in most similar devices.

In operation the cutter is placed sufficiently within the flue, as shown by dotted lines in Fig. 2. By rotating the sleeve nut, the sleeve ring is forced forward, causing the clamping-blocks so firmly to bind against the interior of the flue that the slightest movement of the sleeve and connected parts is impossible. Then by rotating the central shaft to move it inwardly, the inclined walls of the channels will gradually force the cutters outward, as they are carried round with the head.

The inventor has subjected his cutter to severe tests, and has found that flues can be cut with a gratifying despatch and facility.—*Scientific American.*

DREAMLESS SLEEP.

THERE is no such thing as "dreamless" sleep. So we are told by Prof. Baschide, a German man of science, who has been making investigations of sleep and dreams. He does not enlighten us as to how he ascertained that the thirty-six sleepers dealt with were dreaming when they were unconscious. It is stated in the *Daily News* that his subjects were of various ages, from one year to eighty years. In some cases his observations were continued during the whole night, and in others for a great part of the night. He watched and recorded every change of physiognomy, every movement of the limbs, and every speech or sound uttered by the unconscious dreamers. The depth of the sleep was also carefully measured, while from time to time the dreamers were awakened, but without their own perception that the awakening was intentional.

The Professor obtained, as he states at length, the following results:—(1) We dream throughout the whole of our sleep, even in that deepest sleep which we imagine to be "dreamless." (2) There is an intimate connection between the depth of our sleep and the character of our dreams. The deeper the sleep, the further back travels the retrospect into the past experiences of life, and also the more remote is the contents of dream from reality. In a light sleep, on the contrary, the subject of the dream relates to the experiences and excitements of the day, and has a character of probability. (3) In a comatose sleep, the Professor thinks there may, perhaps, be no dreaming. (4) Persons who assert that they do not dream "are the victims of a psychical delusion." (5) Dreams of a moderate character remain longest in the memory; the wilder the dream, the sooner it is forgotten.

THE LIMITING SIZE OF A TWIST-DRILL.

IS there a limit of size for twist-drills above which they should not be made or used; and, if so, what is that limit? asks the *American Machinist*.

There are those whose experience ought to qualify them to judge that think there is such a limit, and that it may be placed at about 1½in. diameter. Yet twist-drills are regularly made by at least one

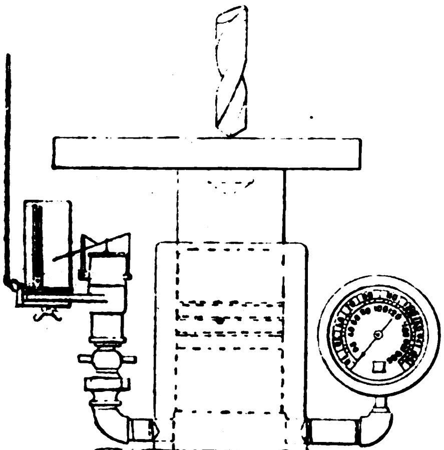


FIG. 1.—Apparatus for Making Drilling Diagram.

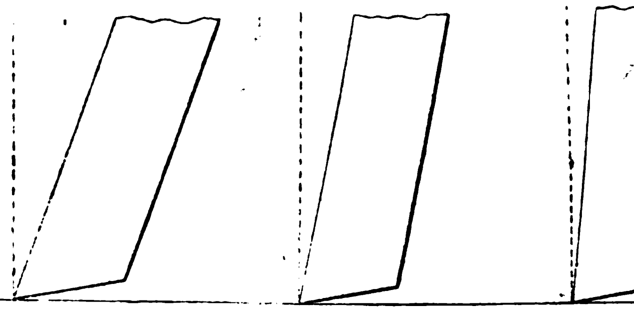
manufacturer up to 5in. diameter, and are regularly catalogued up to 3in., both straight and taper shank.

We all know that it takes considerable force to push a large twist-drill through solid steel, and lots of cast iron is put into radial and other forms of drilling-machines in order to keep the deflection of the arms within a reasonable limit when using large drills. At the same time we know that if we want to enlarge a hole already drilled, and attempt to do it with a twist-drill, it takes little or no force to do the feeding, and, indeed, the drill will feed itself (sometimes much too rapidly) if the first hole is nearly the size of the enlarged one. This proves that when drilling is being done the outer portions of the lips tend to draw in or feed themselves, while the central portion resists this drawing-in tendency; the machine and its feed mechanism having to supply the difference between the two forces. This was very beautifully shown by some experiments made by Prof. L. P. Breckenridge in 1888, and described in the *Journal* of the Engineering Society of the Lehigh University for October of that year.

Prof. Breckenridge asked himself the question, "What pressure comes on a drill-press table when drilling cast iron with a 1in. twist-drill?" and in order to answer this question he made the apparatus shown in Fig. 1. This consists of an upright cylinder, closed at the bottom and fitted with a plunger, the area of which is exactly 10sq in. In the cylinder, below the plunger, oil was placed, and grooves were turned near the bottom of the plunger to answer for packing. On top of this plunger the work to be drilled was placed, so that the downward pressure of the drill would produce a pressure per square inch upon the oil equal to one-tenth of the total drill pressure. At the bottom of the cylinder connections were made to a gauge and to an indicator as shown, and arrangements were made to have the downward motion of the drill-press spindle rotate the indicator drum, so that in this way an indicator diagram is made, its length corresponding to the downward movement of the drill and its height to the downward pressure exerted by it. The drill-press used was built by Prentice Bros., of Worcester, and had back gears and an automatic feed. The plates drilled were of cast iron, and were of various thicknesses—½in., 1in., 1½in., and



FIGS. 2, 3, 4.—Angles of Cutting Lips of a Drill at Various Points.

2in. Some were planed on one side, some on both, and some not at all. Morse taper-shank drills were used, ¼in., ½in., ¾in., 1in., and 1¼in. diameter; they were ground upon a twist-drill grinder, and the iron was of about ordinary hardness—not the softest, nor yet the hardest; 143 holes were drilled, and the last of a series of tables given by Prof. Breckenridge gives the following figures:—

Dia. of Drill. Inches.	Maximum Pressure on Drill while Drilling at Start.	Maximum Pressure on Drill while Drilling with Full Diameter of Drill.
¼	400lb.	350- 400lb.
½	900 ,,	800- 900 ,,
¾	1,100 ,,	800- 900 ,,
1	1,450 ,,	1,000-1,150 ,,
1¼	1,800 ,,	1,000-1,150 ,,

These figures speak eloquently of the force required to push the central part of a drill into cast iron, and when drilling steel the effort must, of course, be much more severe. They also show that in the case of the 1¼in. drill, for instance, as much as 800lb. drawing-in force was exerted by the outer portion of the lips of the drill, and the central portion not only used up this force, but required 1,000lb. more to be supplied to the feed mechanism. In other words, they show that when the outer portions of the lips of a drill begin cutting they tend to pull into a solid hole, the same as they do when we try to enlarge a hole with a twist-drill, and that this pulling-in simply relieves the feed motion of a part of the work of pushing the resisting central portion through.

We are in the habit of thinking of the angle of the spiral of a twist drill as being what we see when we look at the drill, i.e., the angle at the outer edge of the groove. This angle for medium-sized drills, say from ½in. up, is about 20 degrees, as shown in Fig. 2, which we may take to represent the outer surface of one side of a twist-drill with its spiral lines straightened out. But really most of the cutting edge has much less cutting angle, or rake, and if the lips were carried to the centre they would have none. Taking the central portion of a 5in. drill, for instance, equal to half the total diameter of the drill, and the angle of the spiral would be as in Fig. 3; and going down to 1in. diameter, the angle is as shown in Fig. 4. At the centre this drill is ⅛in. thick, and must be literally pushed through the work, or, if thinned on the point, as is sometimes done, and ought always to be done with large drills, the cutting angle is necessarily a negative one, and the stock is simply crushed or pushed off by that portion of the edge.

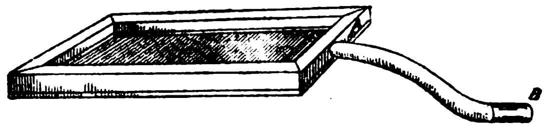
It is this central portion of the drill which must be forced through the work, while the outer portion must be held back to keep it from screwing itself through at a rate entirely too fast for the safety of the drill. This, of course, sets up two opposing forces within the drill itself, and if the centre of a drill be made too thin it splits lengthwise, while if it be made too thick, the resistance of that portion becomes enormous.

What is thought by many to be a better plan is to use ordinary drills up to about an inch diameter, and then follow with a tool which resembles the outer portion of the twist-drill, so far as its cutting action is concerned, but has twice as many cutting edges, and is more efficient as a cutting tool. Its centre is plenty thick enough for great strength, and it follows a drill of from 1in. to 1½in. diameter, according to circumstances. It is believed that holes above 1½in. diameter can be drilled faster by the use of a regular drill followed by this tool, and both of them pushed to the limit of their capacity, than is possible where the full diameter is drilled from the solid at a single operation, and with this tool the drilling-machine needs to supply only the rotating force; the tool will feed itself almost, if not quite.

If Prof. Breckenridge's experiments had extended far enough, so that the figures could have been given for a 5in. drill, the results would probably have been somewhat startling.

APPARATUS FOR REMOVING BUBBLES FROM MOUNTS.

IN the course of my peregrinations among the laboratories of the North of England, I have, upon several occasions, met with a small exhaust apparatus which is used for the removal of air-bubbles from mounts. It is simple in construction and effective in action, and a description of it may not, therefore, be without some interest to readers. It consists of a slip of plate-glass measuring 4in. by 1½in., to which a frame of wood has been cemented. The frame is of such a size as to allow of ordinary glass micro-slips being placed in it. In one side of the frame a hole is bored, and one



end of a piece of indiarubber tube, measuring 6in. long by $\frac{1}{16}$in. diameter, is cemented into it. A piece of glass tubing, B, 1in. in length, is closed at one end, and a small hole is bored through it at about a quarter of an inch from the closed end. The open end of the glass tube is then slipped into the free end of the rubber tube, and the two so arranged that the hole in the former shall be just covered by the indiarubber. To use the apparatus, place the mount containing the air-bubbles in the wooden cell, and cover it over with a second slip of glass measuring 4in. by 1½in., the edges of which have been previously greased with tallow. If the frame has been accurately made the cell will now be air-tight. Exhaust the cell by drawing the air through the tube. The valve formed by the hole will prevent the re-entrance of air, and any bubbles contained in the mount will quickly disappear.—J. H. COOKE, in the *Journal of Applied Microscopy*, N.Y.

FILM PHOTOGRAPHY: THE LATEST PROCESS.

THE latest process of film photography is due to Mr. Albert Hofmann, of Cologne, who gives the following description of it. Smooth, well-gummed, even baryta-weighted or similarly prepared papers, or woven materials, or other flexible bodies serving the purpose, are coated either on one side or both sides with substances soluble in alcohols, ethers, or benzines, such as resin alone or in combination, but at all events not made brittle, but softened through being dissolved in fatty oils or turpentines. The best results are obtained with simple solutions of shellac, gum sandrac, or mastic, with the addition of fatty or drying oils—e.g., castor oil—also with turpentine or the common pine-tree resin, with suitable additions to make and and to maintain the product soft and ductile. Just as good are the soluble albuminous bodies of cereal origin, such as vegetable gluten. After this film is taken up and is dried on, one applies a gelatine coating, to which is added a hardening medium, alum, chrome alum, or the like. With a suitable concentration, one can get a sufficiently thick coating in one operation, otherwise one must repeat the operation often enough to give the final product the requisite strength, in order that it may act as independent negative without any later strengthening. Under certain conditions, gelatine can be applied to both sides of the paper, and, after being dried, coated with a layer sensible to light, whereby it is rendered serviceable for using on both sides. In

this case the original paper must be blackened. The laying on of the sensitive sheet is accomplished in the well-known manner, as well as the development, fixing, and washing of the negative after exposure.

Before the negative is dried, it is placed for a few minutes in a spirit-bath, after which the paper easily loosens itself from the foundation. In order that the separated negative may be hardened and softened, it is now immersed in alcohol containing 5 per cent. of glycerine and 5 per cent. of formalin. The film coming out of this alcoholic glycerine bath is then dried, suitably pressed on to a scrupulously-clean glass plate, varnished, and copied, exactly like every other negative. It can, however, be used as an independent film, without transfer to a glass plate.—*British Journal of Photography.*

CASE-HARDENING.

THE following Report of Committee on Case-Hardening was submitted to the Annual Convention of National Railroad Master Blacksmiths' Association, Milwaukee, 1899, by John Bulkley:—

The process of case-hardening has not changed materially for the past few years. The principle materials used remain the same: granulated raw bone, hydro-carbonated bone black, black oxide of manganese, sal-soda, charcoal, and salt. These materials are commonly used in railroad shops, and give much satisfaction if they be carefully and properly handled. For pins and bushings and such light work as is required for immediate use, we use the "New York Specialty Case-Hardening Powder." This we found to be greatly superior to potash. Specimens of same will be found among samples of case-hardening submitted here for your inspection.

The work which is to be hardened can be packed in cast or wrought iron boxes, sealing with fireclay or mud so as to prevent the gases from escaping as much as possible. The pieces to be hardened should be placed about 2in. apart in box. The vacant spaces are well filled and packed with the material you are using for case-hardening purposes. Should your box be supplied with heavy work, as crank-pins, guides, &c., fifteen to twenty hours of steady heat is necessary in order to secure best results. If, on the other hand, you have light pieces, as links, link-blocks, and pins, eight to ten hours will be sufficient to subject them to a good heat. This class of work we place in the furnace about eight o'clock of a morning, and heat it all day. At night, close up the furnace, letting the box remain over night, and remove next morning. Reheat this work and cool in cold water.

We have secured good results by using granulated raw bone. If using hydro-carbonated bone black, pack pieces in box and seal same as before given. Furnaces for case-hardening should be so constructed that boxes would not have to be raised or lowered while being put into or taken from the furnace. The heating space is near the ground. The firebox and ash-pan are below the surface.

This refers to a furnace heated with soft coal. If the furnace is on outside of a building, a stack or chimney about 16ft. high will furnish draught enough to heat boxes without aid of blast.

Case-hardening furnaces which are heated with fuel oil are of a very different construction, the boxes being generally heated from the top; with coal, in most cases, it is from the bottom. The cooling tub is arranged so as to admit cold water from the end near the bottom, the cold stream thus running lengthwise along the bottom of tub. This cold stream forces the hot water to flow over top of tub. When cooling, guides or long pieces, strips or bars of iron, should be laid in the bottom of tub, in order to keep the work about 2in. or 3in. from the bottom of tub; in this way the cold stream flows under the work which is being cooled.

COLD AS AN APPETISER.

THE benefit of pure air as an appetiser, especially if taken in connection with outdoor pursuits, is well known to every Nature lover. Now it appears that air in liquid form is of benefit to the appetite from the results of lowering temperature.

The Bulletin of Pharmacy is responsibe for the statement that a Russian physician recently placed a dog in a room with the temperature lowered to 100° F. below zero by the use of liquid air. "After ten hours the dog was taken out alive, and with enormous appetite." The Bulletin does not state how much more "enormous" was the appetite after a ten hours' fast in the very cold room than it would have been at normal temperature.

However, the physician was so pleased with the manner in which that dog took to his food that he tried the test himself and reports this result: "After ten hours' confinement in an atmosphere of still, dry cold, his system was intensely stimulated. So much combustion had been required to keep the body warm that an intense appetite was created. The process was continued on the man and the dog, and both grew speedily fat and vigorous. It was like a visit to a bracing Northern climate."

If this theory is to be followed out, a reduction in price of coal and house furnaces may be expected. The reverse effect is true of cold-blooded animals. Prof. Smith, of Yale College, is authority for the statement that frogs may probably be kept alive for several years, possibly even as many as ten, without food in water of uniformly very low temperature.

AIRSHIP OR AËROPLANE—WHICH?

THE quest for a successful means of aërial navigation has been prosecuted along two different lines, according as the inventor aimed at the construction of a navigable balloon or airship, or a flying-machine or aëroplane. The early flying-machines, in which suspension and forward motion were attempted by imitating the flapping wings of a bird, were futile and wofully fatal. In later years they have given place to the scientifically-conceived soaring machine and motor-driven aëroplane. On the other hand, the old pear-shaped balloon, which depends entirely upon the wind for propulsion, has developed into the modern, cylindrical, screw-propelled airship. The progress of invention in aëronautics has been marked, sometimes by a preference for the aëroplane, sometimes for the airship type. To-day, it must be confessed, the latter is most in the public eye, chiefly because of the stupendous proportions of the Zeppelin airship, now nearing completion on its floating dock in Lake Constance.

The popularity of the aëroplane, and the widespread conviction which was noticeable a few years ago that this type would be the machine of the future, were based upon the fact that it was built upon the principles which govern the flight of birds. Since we now understand the laws of flight, and improved materials have enabled us to build flying-machines that are gradually, if very slowly, approaching the bird in their ratio of power to weight, it was argued that the production of a successful flying-machine was a matter of time merely. It is probable, however, that in coming to this conclusion, sufficient importance has been attached to the human element, upon which the successful operation of the aëroplane is absolutely dependent. It would no doubt be possible to build an aëroplane that would carry a person at a fairly rapid speed through the air, provided the occupant of the machine possessed that God-given faculty by which the bird is able to preserve its equilibrium, adjusting the position of its weight and the inclination of its wings to the ever-changing velocity and direction of the wind, and the varying speed and direction of its own flight.

This matter of equilibrium is determined, in the aëroplane, by the inter-relation of several factors, such as the speed, the inclination of the supporting planes, the position of the centre of gravity with regard to the centre of area of these planes, and the inclination of the guiding tail. It requires rare quickness of perception and judgment to keep all these factors in the harmonious equipoise necessary to equilibrium, even under the favourable conditions of a perfectly still atmosphere; but when we remember that every change in the direction and strength of the wind calls for an instant readjustment of the machine, and that a moment's hesitation might result in a sudden dive earthward, the perils of aëroplane navigation will be evident. The fatal mishaps to Lilienthal, Pilcher, and others were due to a failure to control the equilibrium, and the present indications are that as long as the balancing is dependent upon the sensations and voluntary control of the operator, aëroplane navigation will remain a very hazardous and fatal form of recreation.

It is evident that some method of automatic mechanical control is necessary, and the results achieved by Prof. Langley on the Potomac River indicate that such control is within the possibilities of the future. In perfectly still air the Langley steam-driven aërodrome achieved a steady flight of three-quarters of a mile at a speed of thirty miles an hour. But although this was a truly wonderful result, and speaks eloquently for the skill and unconquerable perseverance of the inventor, the aërodrome is to-day nothing more than a wonderfully ingenious toy. It is a far step from that to a machine of commercial or military utility, capable of carrying its freight in any direction in all possible conditions of wind and weather.

The airship (using that term to include all gas-inflated machines), though not by any means so attractive as a scientific problem, seems to be at present the more practicable. For in this type the question of suspension in mid-air has no necessary relation to the speed, as in the case of the aëroplane, and the efforts of the operator may be devoted entirely to steering and propulsion. Given a sufficient volume of gas and a containing cylinder of the proper strength, there is theoretically no limit to the weight which may be lifted. It is in providing a motor sufficiently powerful to propel the huge structure against a strong opposing wind that the difficulty lies. This has never been accomplished as yet, and there is no expectation that even the mammoth Zeppelin airship will be able to make headway against anything stronger than a moderate breeze. Its proposed speed is 22 miles an hour, and hence it will be helpless against a wind of that velocity. Nevertheless, if this distinguished German succeeds in achieving this speed with an airship capable of carrying a crew of several men, he will have placed the problem of aërial navigation on a practical basis which it has never hitherto reached.

The Zepplin airship is of unprecedented size. It consists of a conical-ended cylinder 39ft. in diameter and 410ft. long, carrying two parallel, boat-like cars below it, in which are placed two 15H.P., benzine motors for driving the propellers. The hull consists of an aluminium framework surrounded with a strong netting, within which will be 17 separate, independent, airtight gas balloons, the arrangement resembling that of the watertight compartments of a steamship. The ship will be trimmed by means of a weight sliding on a cable suspended below the cars. By sliding the weight aft, the bow will be thrown up, and the reaction of the air will cause the ship to rise; the contrary movement of the weight will depress the bow and cause the ship to sink. Unless some unforeseen difficulty arises, we may expect to learn the results of the trials of this Brobdingnagian at any moment, and their publication will go far to determ'n the possibilities of aërial navigation on a practical and commercially useful scale.—*Scientific American.*

THE EBONY OF THE ANCIENTS.

EBONY was known and highly-esteemed by the ancients as an article of luxury, and was used by them for a variety of purposes, says the *Jewellers' Weekly.* In India it is said that it was employed by kings for sceptres, and also for images. On account of its supposed antagonism to poisons, it was used largely for drinking cups. Its use has extended continuously down to the present time, and in England, as well as on the Continent, it has always been held in high esteem by the wealthy for toilet articles and boxes. In France particularly the manufacture of ebony goods has attained a high degree of perfection. Within a few years its use in the United States has increased remarkably, in a large measure, no doubt, on account of its combination with silver, which is believed to have originated in this country. The striking contrast of the dead black of the wood and the brilliant white of the silver has from the outset commended it to the American public. This combination, it is said, has now been introduced into England and other European countries. The silver mounting of the ebony gives scope for the taste and originality of the silversmith. The style of decoration most frequently used on the larger pieces consists of a border of scrolls, of flowers, or of a combination of scrolls and floral designs. The variety and degree of elaboration the borders shown are almost endless. Sometimes the border extends only half-way round the edge of the article. A silver shield, on which the initials of the owner may be engraved, is generally placed in the centre of the piece. This shield is occasionally replaced by a monogram, more or less elaborate, which may be the only mountings used. Large initials are also used instead of a monogram. Another style of decoration consists of a beaded edge of silver. While the border is occasionally used on smaller pieces, the decoration for these is generally confined to a shield or monogram. The shield may be combined with floral designs or scrolls. The name ebony is given to the wood of several varieties of trees. All kinds of ebony are distinguished for their great density and dark colour. The wood in all varieties is heavier than water; the heaviest varieties are the darkest. The other grades require a considerable amount of staining to make them black. Ebony is of a uniform colour throughout, and will not show any deterioration even from long-continued use. There are three varieties of ebony well known in commerce. The ebony from the Gaboon coast of Africa is the darkest; the Madagascar ebony is the densest; the Macassar ebony furnishes the largest pieces. Almost all ebony is sent in the form of logs to London, and from there shipped to the various countries in which it is used for manufacturing purposes; it is sold by weight. Imitations of ebony can always be distinguished by their lighter weight, and the cheaper imitations can be detected by merely scratching the surface.

THE most recent discovery of alluvial deposits is in Tasmania. The Mount Bischoff mine, the largest lode tin mine in the world, is situated in that colony. A more recent discovery has been the finding of huge alluvial deposits of great richness and depth. Perhaps the most famous of alluvial deposits referred to is that of the Briseis tin mine, situated at Derby, county Dorset, in the north-eastern tin field of Tasmania.

MAKING AN "S" WRENCH.

THE following method of making a wrench of S shape is given by a correspondent of the *Blacksmith and Wheelwright*. Take a piece of cast steel bar, 1in. square; draw down end 2in. long to fit round hole in anvil. Then cut off, leaving 1in. of square head to the piece as in Fig. 1. Then work round part in hole in anvil, and draw square head each way, working it down to ⅝in. by ½in., or any size wanted, as shown in Fig. 2, and turn up each end to fit size nut wanted. Make two pieces exactly alike, scarf the ends and rivet them together (Fig. 3) and weld, then flatten round part or handle to one-fourth inch thick, leaving ends round. Fig. 4 shows the wrench completed.

PARISIAN INVENTORS' ACADEMY.

THE following curious letter is brought into the light of day by the *American Machinist*, with some appropriate comments. Our contemporary says:—There is in Paris an institution which awards medals to inventors. The inventor apparently has to do almost nothing to secure one of these medals, except to pay 10dol., and he thereby becomes the owner of a medal, the intrinsic value of which may be as much as 50 cents. Numbers of our American inventors have been elected to membership in this academy "unbeknownst" to them, and apparently on the simple announcement of their names and addresses in our *Patent Office Gazette*. This membership costs nothing, but it entitles the member to "the first-class diploma and the great gold medal" (gilded), and for these the 10dol. or "2 pounds St." are required. Naturally, doubts as to the value of this membership, so easily acquired, will arise in the mind of anyone who knows enough to pull on the end of a rope; but such doubts may (perhaps) be set at rest by the following letter, which is printed on the back of a circular letter announcing election to membership of a friend of ours, which friend thinks this is a matter that ought to interest or amuse our readers, especially Captain John's testimonial, which is as follows:—

"Captain John Uster, Paterson, New Jersey,
"U. St. of America, April 3d, 1899.

"Dear Sir: Almost respectfully, I beg you, kindly to accept the following Lines as a Testimony from me, in regard to you Self and the worthy 'Academie Parisienne des Inventeurs.'

"In 1891, I had the pleasure to git acquainted with your Academie;—And since, always was in friendly and often very business like Corespondence with you as President of the Academie;—I confirm here with Pleasure that the Academie have me, as Inventor, promoted to the Rank of a Honorary Member of said Institution.

"The Academie Parisienne des Inventeurs should be recognised as the almost worthy and best one in the whole World!—Indeed i dont testify so in acount of have geting acquainted to the Academie once, either is and in acount of having received Gold, Medal and diplom, o no, it is not the Goldmedal make me testify so, no matter how proud I am about'm, a great deal more was the Inspiration I have received there, I was in a short time quiet an other Man, as i was befor, I could say the Academie did (in 1891) lay the Corne-stone for my Luck afterwards for Lifetime Once a Member of the Academie, the friendly Acting of the Members towards any Inventors will make them improving from Day to Day, the wouldnt let any one doe like the Grandfathers did 50 years ago, o no the want to see any men smarter next morning as the was he Day before indeed exactly so was with myself, the so strickty and lawfull Acting of the Academie towards me was just licke a Spring put in to my whole Body, with nearly the same Effect like a Spur in the Priders Heel towards the Horse,—As i said before: It was the Inspiration, received from your Self and the Academie, that i git up to the point where i am now, only for this i might would not be in Possession of two other Gold, Medals from the Exhibition at Paris, in 1897, because i may was not able to have any Invention to place there - nothing to say about, that I am able to bring 4 other new Inventions to the Exhibition next year 1900.

"Now 3 Cheers for the Academie! And my Sincerely thank for all the Goodness of you all.

"Gentlemen, very respectfully, yours truly, Friend and College:

"Captain John Uster Paterson,
"New Jersey."

GRINDING SHOP TOOLS.

IN the old days every man ground his own tools, or rather the tools he used, and each had a peculiar turn or angle which, in his eyes, made them cut better than any other tool in the shop. This included everything, from drills to milling-cutters, and resulted in a great variety of shapes and sizes. It also took considerable of each man's time, and did not improve the condition of such tools as drills (flat or twist), milling-cutters, or reamers.

The drill-grinder has long been a part of nearly every tool-room, and no one will deny that drills are ground more uniformly and at less expense than by the old way. They also do better work, as the cutting-angle is correct, and, being even, they drill true to size.

The grinder for reamers and milling-cutters is also making its way, and the lathe and planer tool-grinder is the problem in many shops at present. Some have adopted it and are using it with success—others have tried it and are either using it in a half-hearted way, and are not getting all there is out of it, while some have abandoned it altogether and call it a failure.

Its success in large machine shops, however, shows that it can be made a paying investment, while the results obtained in some of the large railroad shops show that it is applicable to this work as well as to any other. The problem is in its application and in deciding when it will pay to introduce the new system. This decided, the next thing is to determine to use it successfully by adhering strictly to the suggestions of the makers.

It is sometimes objected that it takes longer to set the machine and grind a tool than to do it by hand, and the objection shows that the proper use of the tool-grinder is not understood in this case.

Having the grinder, get all the lathe and planer tools in the tool-room. Grind all the turning-tools to the form you select for that kind of tool, and carry this through them all. Have enough of each kind so you always have a supply, and keep them in the tool-room, subject to call. They should be ground in as large lots as possible, as it reduces cost by avoiding setting the machine so often.

When a tool is dull, let it be brought (or sent in a large shop) to the tool-room and exchanged for another—the dull ones can be ground when enough have collected. Two or three can be issued at once to avoid delay between tools, and the machines kept constantly at work.

The main difficulty in introducing this seems to be in not doing it entirely according to the ideas under which it was designed to work, or of trying to compromise the old with the new. With each man going to the grinder, setting it and grinding his tools, it becomes an expensive tool, although still having the although still having the advantage of uniformity. But with all the tools of the shop ground by one man—or more if necessary—there should be an increase in production. And unless the system is thoroughly carried out, there is little use in buying a grinder, for, like many other tools, they can save or lose money according to the way they are used.—*Locomotive Engineering*, N.Y.

A method of thawing water-pipes by electricity has been put to the test in Canada. Alternating current at a pressure of 20 volts to 50 volts is used, obtained from a portable transformer connected with the street mains; a current of 200 to 400 ampères is passed through the frozen pipe until the water flows freely, which usually takes place in a few minutes.

A Lobster in a Short Jacket.—"One must live," said the tramp. "No," replied the cynical alderman, "I don't see the necessity." So writes the Rev. Thos. R. R. Stebbing, F.R.S., in *Knowledge* for December. But, at all events, in order to live, one must breathe. This is indispensable alike to tramps and aldermen and crabs, and to every item of the animal world. Some minute organisms may be dessicated by heat or frozen by liquid air into a state of suspended animation, and a stuffed lion in a museum, or an embalmed Pharaoh in a pyramid, may out of courtesy still be called an animal, though each ceased to be one as soon as the breath was out of its body. Breath being so essential, respiration, like perspiration, all over the surface, wears the aspect of an advantage. It is, in fact, not to be despised, and, such as it is, this advantage is enjoyed by several animals, and among them by some of the crustacea. But with increasing complications of structure and existence, more than one consideration comes into play, as the greedy boy, who wished that he was all mouth, would speedily have discovered. Nature, in her more elaborate efforts, utilises division of labour, and allots special organs to special functions. Anyone who has used a hammer for cracking open the claw of a crab will understand how unsuitable a surface for respiration would be afforded by that stony, water-tight integument. In bringing to perfection her wonderful karkinokosm, Nature certainly did not begin by making crabs, but rather in that line of business produced them as the crown of her operations. To follow Nature, then, we must not begin by investigating the breathing apparatus of a crab, but follow down the line till we come to something simpler. Pause, then, at the amphipods. Specimens can be had without cost. An amphipod might be familiarly described as a lobster in a short jacket. It differs from the lobster in that its eyes are not movable on jointed stalks. With its whole body so small and nimble, separate ocular mobility could scarcely be needful to it. Otherwise, in the general inventory of its kit, this little campaigner agrees with the lordly lobster, thus:—Antennæ, two pairs; one upper lip, one lower; one pair of mandibles; maxillæ, two pairs; maxillipeds, three pairs; and five pair of trunk legs. By all means catch a *Gammarus pulex* in the rivulet that runs through your park, or a *Gammarus locusta* that slidders under weeds and stones on almost any sea-shore, to see whether I have counted right."

SCIENTIFIC NEWS.

THE eclipse of the moon seems to have been well observed from many districts, but the accounts of the colours vary. When the greatest phase was reached, the moon appeared of the dull copper colour so well known, and it was noted that the crescent at and near the greatest phase appeared to be part of a circle larger in diameter than the boundary of the eclipsed portion—the effect, probably, of irradiation. The late eclipse was very little short of being total; but it is very rarely that the moon entirely disappears in even a total eclipse.

Another small planet was, it is stated, discovered by M. Charlois, of Nice, on Dec. 4, and, if it is verified, it will increase his number of discoveries —already the largest—to ninety-five.

Prof. H. H. Turner, the Savilian professor of astronomy at Oxford University, has issued (London: Henry Frowde) "the Day Numbers of the *Nautical Almanac* for the years 1900, 1901, 1902," modified for use with the tables of the star constants arranged by the late E. J. Stone, M.A., F.R.S.

"Precession Tables adapted to Newcomb's Value of the Precessional Constant and reduced to the Epoch 1910·0" have been issued by Dr. A. M. W. Downing, M.A., F.R.S., through Neil and Co., Ltd., Edinburgh. The tables can be used from 1900 to 1920.

A course of eight lectures on the methods of spectroscopy, especially in connection with the photography of the spectrum, will be delivered at University College by Mr. E. C. C. Baly, commencing on Jan. 19, 1900, and continuing on following Friday evenings.

The date when the 20th century commences seems to still be a puzzle, and the following paragraph (the statements in which may not be true) is widely published:—"In Sweden the next century is to be considered as beginning with Jan. 1, 1900. According to a Dalziel's message there are many Swedes who hold the view that the next century will not be entered upon for another twelve months; but in order to overcome their objections and remove their scruples the bishops and clergy generally of Sweden have been requested to dwell specially upon this point in their sermons on the concluding Sunday of the year. Further, all the church bells will begin to ring at midnight on Sunday for half an hour to welcome not only the new year but the new century." It is not stated by whom the "bishops and clergy," &c., have been requested to dwell, &c.

The Christmas lectures at the Royal Institution will be delivered by Prof. C. V. Boys, F.R.S., on Dec. 28 and 30, and Jan. 2, 4, 6, 9. The subject will be "Fluids in Motion and at Rest."

The Friday evening meetings of the Royal Institution commence on Jan. 19, when Lord Rayleigh will deliver a discourse on "Flight."

Amongst the lectures already announced at the Royal Institution may be specially noted a course of three by Prof. H. H. Turner, M.A., F.R.S., the Savilian professor at Oxford, on "Modern Astronomy," to be delivered on Feb. 8, 15, 22.

A Congrès International des Sciences Ethnographiques is to be held in Paris on Aug. 26 – Sept. 1, 1900. There will be seven sections. The secretary is M. Greverath, rue d'Athènes 3 bis, Paris.

At the preliminary meeting in connection with the British Congress on Tuberculosis to be held in the spring of 1901, Sir Samuel Wilks, ex-President of the Royal College of Physicians, said they all knew that tuberculosis was a bacillus, a living organism peculiar to tubercle. In consequence of that discovery came the natural corollary—that that bacillus might be carried about by air or food, and was therefore infectious or contagious. One of the objects of that society was to appeal to the public to enable them to obtain new hospitals or sanatoria where patients might be cured of that disease. A pioneer in this subject, the late Dr. MacCormac, of Belfast, gave nearly all his time and his energy to advocating the treatment of consumption by fresh air breathed night and day, especially at night, with open bedroom windows. He said that this was the best way of curing the disease. The disease was especially prevalent in oxen and cows, and was propagated by the food which people ate and also by the milk they drank. These facts, which he had mentioned with reference to the disease of tuberculosis, were accepted now all over the world with perfect unanimity of opinion in the medical profession in every civilised country; but, inasmuch as we were so closely associated in the present day by travel and otherwise, it did seem desirable that they should meet together to discuss this matter in common, and that some common methods of action should be proposed.

The death is announced of Dr. John Frederick Hodges, Professor of Agriculture and Lecturer on Medical Jurisprudence in Queen's College, Belfast. Educated at Trinity College and the Royal College of Surgeons of Dublin, he became, in 1837, a licentiate of the Faculty of Physicians and Surgeons of Glasgow, and afterwards studied in Germany, where in 1843 he graduated doctor of medicine in the University of Giessen. He then applied himself to the study of analytical and agricultural chemistry; and subsequently filled the office of chemist to the Chemico-Agricultural Society of Ulster; analyst to the city of Belfast and to the counties of Antrim, Tyrone, and Donegal; Professor of Chemistry, Royal Belfast College; Examiner, Queen's University, Ireland; and president of the Natural History and Philosophical Society and of the Royal Academy Institute, Belfast. He was also an honorary member of the Academy of Agriculture of Sweden, and many other scientific societies. Dr. Hodges was nearly, if not quite, the oldest member of the Chemical Society of London, having been elected a Fellow in 1844—three years after the formation of the society. He was the author of the following works:—"First Book of Lessons in Chemistry for Farmers and Teachers" (a work which reached a 12th edition in 1862), "First Steps in Chemistry," "The Structure and Physiology of the Animals of the Farm," and contribution to the reports of the British Association, the *Medical Gazette*, and the *Journals* of the Chemical Society. He was also for some years editor of the *Journal* of the Chemico-Agricultural Society of Ulster.

Sir Richard Thorne Thorne, principal medical officer of the Local Government Board, is dead. He was born at Leamington in 1841, and was the son of a banker there. After passing through Mill Hill Grammar School and the Lycée St. Louis, Paris, he became a student at St. Bartholomew's Medical School. Sir Richard, who obtained his M.B. degree with double first-class honours, was the author of several important medical works. As a member of the General Medical Council, he has represented Great Britain at the principal international sanitary conferences at Venice, Berlin, and other cities.

Mr. Bernard Quaritch, the famous bibliophile, died on Sunday last at the age of eighty-one. During his long career he has bought and sold most of the rare books and MSS. which have come into the market, and of late years he has purchased all copies of the Mazarine or Gutenberg Bible which have come into the market. He was one of the founders of the "Ye Odde Volumes," a society of bibliophiles founded about twenty years ago.

Mr. James Robertson, who died recently in his seventy-ninth year, was one of the most prolific inventors of the day in the engineering world, more especially in connection with hydraulic machinery for the manufacture of tubes of various metals.

Mr. David Peebles is also dead in his seventy-third year. He, too, was an inventor, especially in connection with gas appliances—his needle burner and governors being widely known. He was a Fellow of the Royal Society of Edinburgh.

One of the greatest railway builders in America died the other day. Mr. John Insley Blair was born in New Jersey in 1802. He built more than 2,000 miles of railway in Iowa and Nebraska alone. When the Pacific railroad was proposed it was found that the cost of transporting the rails by river would be ruinous. Mr. Blair was therefore urged to complete his own connecting line across Iowa, which he did in less than a year, thus earning a million acres of land by way of premium, besides the great profits from carrying the rails, merely for finishing his own road. Beginning with 1860, he was connected with the construction of most of the great land-grant roads east of the Rocky Mountains. Though little heard of in the great railway combinations of recent years, there have been few of importance in which he did not have some part. He was a life-long Presbyterian, and gave about 500,000dol. to various institutions, mainly universities and colleges connected with that denomination.

M. Henri Becquerel has been recently investigating the phosphorescing properties of radium, and he discovered that the rays given off by chloride of barium containing the new (?) element radium produced luminosity in all the minerals which become luminous under the influence of X rays. Many differences were, however, noted, for ruby and calc spar remained unaffected by the radium, while diamond became brilliantly luminous. The subject will no doubt engage the attention of students of phosphoresence and radiation for some time. M. Becquerel has communicated his observations to the Paris Academy of Sciences.

M. Armand Gautier, in a memoir presented to the Paris Academy of Sciences on the presence of arsenic in certain organs of animals, says that it is present as a normal constituent of the thyroid gland in the herbivora, the carnivora, and in man. As it appears that it is also present in other organs the successful use of arsenic as a remedy in certain diseases — for example, anæmia and Basedow's disease (goitre, &c.)— would appear to be explained. The memoir will attract the attention of toxicologists, for arsenic-eating has been known as a habit for many years.

In a memoir presented to the Paris Academy of Sciences, M. Berthélot refers to the explosive properties of chlorate of potassium. He finds that if the chlorate is suddenly placed in a vessel at a higher temperature than that at which decomposition commences, the salt explodes, though if slowly heated the chlorate does not explode. The investigation was probably made in consequence of a comparatively recent disaster in Lancashire.

At a meeting of the Staffordshire Iron and Steel Institute, last Saturday, Mr. H. B. Toy read a paper on "Iron and Steel Works Plant," in the course of which he said that it was well established that for many purposes steel had superseded iron; but he firmly believed that if the heads of departments in ironworks would study more closely the question of economy of production, and improve their plants by judicious expenditure, the iron trade of the district would die a much more lingering death than was frequently predicted. The question of railway rates very seriously affected not only the development of any new industry in the Midland counties, but was gradually compelling manufacturers either to discontinue an old-fashioned business or seek, at a very great cost, some more convenient site at the coast or elsewhere. If the members of that Institute could in any way prevail upon the railway companies to make a concession in their rates from the Midlands to our shipping ports, they would not only benefit themselves, but confer a great blessing upon many other branches of industry. He did not recommend all owners of ironworks to dismantle their plants and replace them with something quite different, but to make the necessary modifications to those details which seriously affected the cost of production, and which in many cases could be done at a small expense. Mr. Toy condemned the practice of replacing old egg-ended cylindrical boilers with new ones of the same pattern. Several attempts, he said, were being made in Staffordshire to roll steel sheets in old iron mills; but, considering the many difficulties, he was afraid the trials would not be attended with very great success. The ultimate monopoly in the steel trade would be vested in those who had their own blast-furnaces, steel-smelting works, and sheet works. His impression was that in the near future steel sheet bars 18in. wide would be rolled direct from the ingot in a universal reversing two-high mill.

At the monthly meeting of the British Ornithologists' Club an agreeable surprise was in store for the members in the exhibition of a remarkably fine egg of the great auk, hitherto unrecorded and recently discovered. The specimen is said by the experts to be unsurpassed in beauty and preservation. The number of eggs of this extinct bird now known to be in existence is seventy-two, fifty-four examples being in England. The birds exhibited included several species new to science from the New Hebrides (from which islands Capt. Farquhar, R.N., has recently brought home a small but extremely interesting collection.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]

All communications should be addressed to the EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

*** *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks; a vice from whence great inconveniences derive their original."
—*Montaigne's Essays.*

THE ECLIPSE OF THE MOON.

[43118.]—THE lunar eclipse was well seen here, the atmospheric conditions being very favourable. The moon shining through the shadow was of a coppery red colour, more ruddy in the northern hemisphere. During the eclipse several stars were occulted, which could not have been observed unless the moon was undergoing eclipse. Of these occultations there were at least four, and possibly others beyond reach of my instrument; the disappearance was in all cases quite sudden. The eclipsed moon hanging over Orion, with the rich region of stars around Aldebaran on the right, and Sirius shining brightly low down on the left, formed a very impressive astronomical picture.

Earlsfield, S.W. **Silverplume.**

[43119.]—HAVING observed and reported on in "Our" pages a number of lunar eclipses within the last ten years, I may say, by way of preface to a more minute description of last Saturday's superb spectacle (astro. reckoning), that the peculiarities of the eclipse from my point of view were: The very marked evidence of penumbral shading over the "seas" between 11h. 25m. and 11h. 45m., and the curious way in which this shading seemed to avoid the Polar regions. The sharply defined advancing edge of the shadow, even when scrutinised by a power of 80 on 3in. refractor. The alternate transparency and opacity of the shadow itself, and the very close approximation to totality at the time of maximum phase.

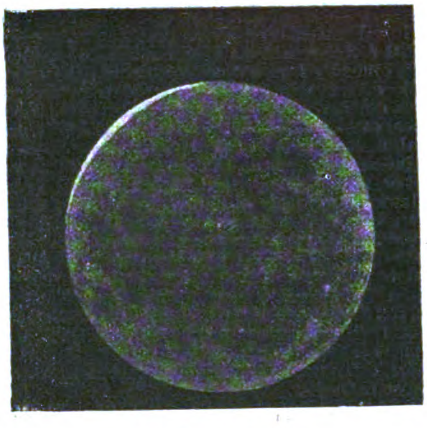
Employing throughout a power of 80 on 6in. o.g. and using a diagonal to avoid getting a permanent crick in the neck, the progress of the phenomenon could be very conveniently noted. At 11h. 25m. the penumbræ shading over the "seas" forcibly suggested the idea that a dilute specimen of London "peasouper" was paying its attention to the lunar lowlands. During the next five minutes this fog seemed to gain much in density, and the intense whiteness of the regions south of Tycho and north of Plato suggested a considerable elevation above the smother; by 11h. 40m. however, the "fog" seemed to have nearly forsaken the *Mare Serenitatis*. At 11h. 45m. a deep brown discoloration in the E.N.E. bespoke the close proximity of the shadow itself to that neighbourhood, and 90sec. later Aristarchus was immersed in it. For some time afterwards this object could be seen at intervals very conspicuously, while now and again it disappeared completely. The eclipsed limb of the moon became visible by 11hr. 50min., at which time the area in shade was very dark, and there was a very deep band following advancing edge of shadow. The South Polar regions were still intensely white. Five minutes later the eclipsed limb was lost to view in some places, but distinctly visible in others; whilst with the lapse of another ten minutes it reappeared in its entirety to remain on show. By midnight the area of the moon in shadow became visible, and so continued throughout the time I was watching; but the transparency of the shadow varied momentarily, so much so that one was tempted to think there must be heavy masses of cloud in the lower atmosphere about the margin of the earth seen from the moon.

Generally, the colour of the umbra seen in the telescope was a deep grey, but at times I suspected a greenish tinge in it; whilst one or twice it assumed quite a turquoise appearance. To unassisted vision the eclipsed area of the moon maintained a "coppery" look throughout; but the ruddy tinge sometimes so noticeable was to my vision entirely lacking. Near the time of middle eclipse the lunar disc strongly resembled an iron one at a dull red heat, with dark patches near the centre, and the lower edge raised to welding temperature. I quite expected to witness a rehearsal of "the old moon in the new moon's arms," but in this I was disappointed; for, until my last look at the progress of the phenomenon I could detect no "irradiation" effect. The said last look took place at 13h. 38m., at which time the result sought was easily obtained. Certainly 0 005 of the lunar disc is a very small portion; but at 12h. 30m. it seemed to me that all that was not involved in the actual umbra might have been more moderately described as equal to 0·0005, which, however, might easily be accounted for by the greater density of the penumbra contiguous with the shadow. I think that, on this occasion, at any rate, the visibility of the eclipsed limb of the moon might be fairly set down to "contrast" effect, for, although it was, as a rule, very clearly defined, it did not appear nearly so conspicuous to me as did the said limb on the occasion of the last lunar eclipse witnessed by myself—to wit, the small partial eclipse of Jan. 7, 1898. Altogether, it was a most fascinating spectacle—the eclipse of yesterday—and as we poor stay-at-homes are not likely to see anything of the sort again on so large a scale before April 22, 1902, and that only indifferently, it is worthy of remembrance.

William Godden.

West Hampstead, N.W., Dec. 17.

[43120.]—THE almost total eclipse of the moon last Saturday night afforded a pretty spectacle to possessors of small instruments. Even an aperture of 2in., with a low power, say, 30 diameters, was quite sufficient to yield an excellent view of the earth's shadow as it crept over the lunar hills and dales, and swept across brilliant sunlit plains, each shining peak stoutly resisting the obliterating effects of the smothering pall. Of course, the darkening was greatest in the moon's northern hemisphere, particularly to the eastward over the vast low-lying tracts constituting the Oceanus Procellarum and



1.15 a.m., Dec. 17.

the Mare Imbrium. Here the disc glowed with a dull blood-red hue as of heated iron, an effect due to the refractive power of the earth's atmosphere, which bends a small proportion of the solar rays into the cone of shadow, reddening the dim light in the process. Here is a sketch of the phenomenon as it appeared ten minutes before maximum, at which moment a curtain of clouds covered the sky, and precluded further observations.

Norman Lattey.

THE PERIODICITY OF SUNSPOTS.

[43121.]—(1) THREE years ago (Oct. 30, 1896) the "E.M." was good enough to publish a letter (39257) from me on the above subject containing an hypothesis or theory to account for the spots and the periodical variation. The theory was that the formation of sunspots is dependent upon the law of the conservation of energy and the law of gravitation. The orbits of the planets being elliptical, the moment a planet has passed its perihelion the sun's gravitation slackens its speed something after the fashion in which the speed of a railway train is slackened by putting on the brake when it runs into a station. And as action and reaction are equal, the law of conservation of energy steps in, and the planets react upon the sun, and this reaction produces sunspots. (I am fully aware that the preceding sentence may not be considered quite orthodox; but—"There are more things in heaven and earth, Horatio," &c.) Consequently, as the sun is attended by one giant planet, Jupiter, whose mass is more than double that of all the others added together, the average period of sunspots must be precisely equal to the period of Jupiter's revolution—namely, 11·86 years. But this is over or underlapped by the periods of the other planets. The theory was, in fact, that sunspots are only produced when planets are on the up side of their orbits—i.e., on that side on which a planet is rising from the sun towards its aphelion, and that when it is on the down side—i.e., on that side on which it is nearing the sun, no spots are produced. My letter further showed, or rather proved that out of thirteen recorded maxima and minima the last eleven precisely fitted the theory, and that the two non-coincident ones were the first two that Schwabe observed early in the present century.

(2) I read in the "E.M." on Oct. 27, in the article on "Astronomical Occurrences for November" that "as the sunspot minimum has now definitely arrived, and that as the last minimum was in 1889-6 so that 10·1 years only have elapsed since, the period of 11·11 years of certain textbooks has thus broken down entirely." Is not this opinion rather premature? What has the above theory to say upon the subject?

(3) A reference to the *Nautical Almanac* shows that from October 23 to December 6 five out of the six primary planets nearest the sun were, according to the theory, *hors de combat*, so far as producing sunspots is concerned. Saturn is near his aphelion, and Jupiter, Mars, Earth, and Mercury were on the down side of their orbits. The only one of the six on the up side of its orbit was Venus, whose orbit is so very nearly circular that it would not be likely to produce sunspots. Here, then, the theory fully accounts for the minimum, and at the same time indicates that the long average of 11·86 years has not "broken down entirely."

(4) On December 6 the above state of affairs came to an end. The planet Mercury, whose orbit is the most eccentric of all the above-mentioned six planets, passed its perihelion, and is now sweeping along the up side of its orbit, and by the time this letter is published will be 90° in longitude distant from its perihelion. Even as I write I notice that a fresh crop of small spots is breaking out on the solar disc, and this fully agrees with the theory.

Ryvecton. **W. A.**

SUNSPOT CYCLES.

[43122.]—WITH reference to the letter (43107) in your issue of yesterday, *re* the sunspot cycle, will you allow me, as having foreseen the great diminution in sunspots which occurred early in July last, and the subsequent dearth of spots, to say that I have as good reason to anticipate a resumption of sunspot activity between March 1 and July 1 next, and thereafter continuing without lengthy interruption until the autumn of 1903.

The bodies causing the spots move so slowly that I am unable to more closely fix the date of resumption of activity. **Alex. Hutt.**

Member British Astronomical Association.

THE SATELLITE OF NEPTUNE.

[43123.]—"ELL HAY" (in letter 43111, p. 406) states that his "N" Telescope (Newtonian) shows the satellite of Neptune, though very faint. In the same letter, when mentioning another observation, he gives the aperture as 5½in. As the satellite of Neptune has not been seen steadily with so small an aperture, so far as I have seen recorded, will "Ell Hay" kindly give your readers first the date of his observation and the hour; second the aperture employed and power used; third whether satellite was seen steadily or by glimpses; four the position angle and distance, either measured or estimated.

Dawes with 8in. Alvan Clark refractor, Ward with 4·3in. Wray refractor, and Sadler with 6½in. Calver reflector, have all seen the satellite, but not steadily. **Neptune.**

THE LOST LEONIDS.

[43124.]—THE conclusions to which Dr. Johnstone Stoney and Dr. Downing have been led regarding the non-appearance this year of the expected meteoric display must cause considerable surprise to those who, for so many years past, have been led by those in authority to anticipate with confidence their due return, inasmuch as the abnormal effect likely to be produced upon their orbit by the perturbations of the giant planets during their late revolution round the sun could scarcely fail to have been recognised by those who have given their attention to the matter, although, possibly, the exact allowance to be made on this account could only be determined by elaborate calculation. What strikes me as vary remarkable is, that during the many centuries that their history can be traced back, no such abnormal conditions should at any time previously have prevailed, or that during such interval the accumulated effect of the entire series of perturbations experienced has not been sufficient to produce a similar result.

Although that portion of the stream through which the earth passed in 1866, and to which the calculations have been specially directed, will not reach the node of its orbit until the middle of February next, the perturbing effect upon this portion would not, I presume, differ very materially from its action on that part which reached it in November, and which is probably situated near the front of the stream, and as the effect, according to Dr. Downing, would be still more apparent in that portion which will be nearest to the earth next November. I gather from his remarks at the B.A. meeting that, in his opinion, we have now lost the ortho-stream altogether, and the utmost that this or future generations can hope to see will be a few outlying stragglers of the system.

W. T. N.

THE GEMINIDS, 1899.

[43125.]—THE weather during the Geminid epoch was extremely poor. Clouds, rain, fog, snow, and frost all combined to make observation very arduous and difficult.

The watches were divided into two parts:—

1. December 1—10. On and between these dates observations were made in the evening. After the 10th the light of the moon was too strong to allow a profitable look-out to be kept.

2. December 11—13. The observations were now conducted in the early morning.

The following table gives a more detailed account:

1899.	From.	To.	Meteors Seen.	Meteors Rec'rd'd	Geminids Seen.	Geminids Recorded	Seeing.	Remarks.	Hours of obs.
	h. m.	h. m.							h. m.
Dec. 1	10 0	11 0	6	6	0	0	2	——	1 0
,, 2	—	—	—	—	—	—	-	Sky overclouded	—
,, 3	—	—	—	—	—	—	-	Rain falling	—
,, 4	—	—	—	—	—	—	-		—
,, 5	—	—	—	—	—	—	-	The state of sky rendered	—
,, 6	—	—	—	—	—	—	-	observations impossible..	—
,, 7	—	—	—	—	—	—	-		—
,, 8	9 35	11 10	9	8	2	2	2	Moon up during greater part of watch, but its light had little effect on observation.	1 35
,, 9	—	—	—	—	—	—	-	Sky cloudy	—
,, 10	—	—	—	—	—	—	-	Sky cloudy	—
,, 11	—	—	—	—	—	—	-	Early morning 12th snowing	—
,, 12	—	—	—	—	—	—	-	Snow falling	—
,, 13	17 10	18 30	5	5	0	0	3	——	12 20

In the above table "2" means good, "3" fair.

It will be seen that out of 13 days, observation was possible on only three occasions. The total time spent in watching the sky was 3h. 55m.; 20 shooting stars were seen, of which 19 were mapped. Two meteors were Geminids. This cannot be taken as a sign of paucity of meteors belonging to that shower, because the sky on nights and early mornings of the days of maximum was entirely overcast. On the early morning of the 14th not a single meteor from the shower was seen during a watch of nearly $1\frac{1}{4}$ hour.

On projecting the paths of the two Geminids seen on the 8th with another meteor from the same radiant observed earlier in the evening, I find a centre at α 105°, δ + 34°.

Of the minor showers, that of the α Orionids was prominent on December 1. During one hour three bright meteors from a fairly definite radiant at α $84\frac{1}{2}°$ δ + $9\frac{1}{2}°$ were seen. Their magnitudes were > 1, 1, 1.

On December 13 three υ Ursids from a radiant at 145° + 57° were recorded.

Other showers furnished less prominent displays; but observations were only possible on three widely separated occasions. This latter fact prevented a large number of meteors from any one shower being observed.

Leicester, Dec. 18. **A. King.**

METEOR.

[43126.]—IN letter 43075 Mr. N. Maclachlan raises the query as to whether the meteor he saw on the morning of Nov. 15 was the same as the one I saw near the radiant point on that same date. This meteor seemed to be coming straight at us both, although separated as we were by a distance of about 400 miles. I am sorry to say that I have not a record of the time the meteor appeared; but, as far as I can remember, it was about the time he mentions (4.50). Even if I had a note of the correct time, and it was similar to Mr. Maclachlan's, it would be difficult to believe that it was the same meteor. For, as he remarks, "it seems impossible, with the estimated depth of the atmosphere, that the same meteor should appear to be coming straight towards the eye of two persons at a distance of something like 400 miles apart." For such a state of things to be possible, we should have to have a depth of atmosphere of some thousands of miles, instead of less than a hundred, as it undoubtedly is.

Wm. H. Daw.

9, Belgrave-road, St. John's Wood, N.W.

HOROLOGICAL—STAR TRANSITS.

[43127.]—I HAVE recently come into possession of a long-cased clock, by "John Wilks, Evesham," and should be very grateful if any of your numerous correspondents could give me a little information about the old clock and its maker?

The mahogany case is about 7ft. high, with Corinthian pillars and gilt mountings; dial, silvered, 13in. diam., figures and maker's name finely engraved and waxed in. The hours and minutes circle is not concentric, but is placed at the bottom of the dial below the centre hole. The seconds-hand is much longer, working from the centre of the large dial, and marking seconds at each beat. (Am I correct in supposing it was originally intended for an astronomical regulator?) Escapement dead beat pallets worn; want renewing. I notice the seconds-hand moves farther one beat than the next one, marking, say, $\frac{3}{4}$sec. one beat, and $1\frac{1}{4}$ the next. Is this due to worn pallets? When the clock came into my hands it had two weights of 16lb. each, which was at once seen, owing to the rapid striking, to be much too heavy, and after some experimenting I found 6lb. on a double line, both for the going and striking part, was about correct. Would it be advisable to file out the worn pallets and fit some hard substance for the teeth to act on, or, better, to make new steel ones. Any information would be welcome, both as to the clock and its probable date.

Now I am writing about timekeepers, perhaps "F.R.A.S." would be kind enough to explain a little difficulty I cannot quite get over. In various books dealing with times of star transits, instructions are given for obtaining local mean time at places east or west of Greenwich; but I don't want local mean time, but Greenwich mean time at Maidstone, which is said to be 2 minutes 10 seconds east or fast of Greenwich. Am I correct in the following:—Suppose Sirius is stated to south at Greenwich on Jan. 1st at 2 minutes 10 seconds past 10 p.m. Greenwich mean time. Would that star south at Maidstone 2 minutes 10 seconds earlier—that is to say, at 10 p.m. exactly. It is easy to obtain time from Greenwich signal occasionally, and if the above is correct, I could easily check a clock that is keeping nearly correct Greenwich time. I have never seen this question answered before, and should feel much obliged for information on this point.

Maidstone. **E. P.**

FIRE-BALLS—THE DELUGE.

[43128.]—MR. WRIGHT'S account of the train of the Littlemore meteor is very interesting. It suggests to me that observers should make more careful observations on the trains of meteors which last for any appreciable time. Such meteors or fireballs are pretty certain to be seen from several stations, and their paths through the air can thus be approximately determined. We thus learn the original position of the train. If, then, we could also observe the angular rate of shifting as well as the direction of the shift, we should obtain important information as to currents in the upper region of the atmosphere. Some apparent shifting, however, might, I apprehend, be caused by the sinking or rising of the train—sinking being more probable than rising. For it would thus get into a region where the velocity of rotation was greater or less than before. This rising or sinking, however, ought to involve an apparent lengthening or shortening of the train.

Your correspondent "F.R.A.S." seems to forget that Mr. Garbett's deluge occurred in B.C. 3102, and is not therefore in the least affected by the Chinese observation referred to. But what of this observation itself? I find from Mr. Williams's book that a conjunction of planets is recorded as having occurred in the reign of Chuen Kuh, which lasted for 78 years (a rather startling incident to commence with). This 78 years is set down as lasting from B.C. 2513 to B.C. 2436. Mr. Williams adds that according to a modern computation (he believes by Bailly), the conjunction took place on February 29, B.C. 2449. He then says, "Should this, on further investigation, prove correct, it will afford a strong presumption of the authenticity of the early Chinese annals," because the Chinese astronomers had not sufficient knowledge to arrive at the date by computation.

I see that "F.R.A.S." gives the date of the conjunction as February 18, B.C. 2446, instead of February 29, B.C. 2449, so I suppose he has some new authority. He also speaks of a conjunction of four planets; but, according to Mr. Williams, the Chinese record relates to a conjunction of five—the entire number then known. Under these circumstances I do not feel confident that both Usher and Garbett may not survive the Chinaman's attack.

I find that "F.R.A.S." has followed Chambers's "Handbook of Practical and Descriptive Astronomy," Vol. I. p. 70, of the last edition, as regards the date of the Chinese conjunction of the planets. But Chambers mentions that another computation gives February 9, B.C. 2441, as the date, and in both cases the computed conjunction is one of four planets; whereas, according to Mr. Williams, the Chinese record is a conjunction of all five. I need hardly say that Jupiter or Saturn could not have been seen in the same part of the sky in February, B.C. 2441, 2446, and 2449. Some of the computations must therefore have been egregiously wrong.

W. H. S. Monck.

NEWTONIAN—GREGORIAN.

[43129.]—I READ the interesting letter of "Ell Hay" with much pleasure. Apparently he has managed to make his telescope serviceable under both forms. He must have a fine mirror and a good eye to divide Zeta Boötis and pick up the companion to Mu Andromedæ. Will he tell us if he notes any difference in the focal images under the two forms, such as "H." proved should occur? An American professor has shown incontestably that the Newtonian suffers from incurable defects. The images formed by the margin are larger than from the centre, and are at varying inclinations to the cube axes, and from these results the well-known defective definition of that form of telescope. "H." and others have shown that the Gregorian construction eliminates these errors, and it would be interesting to know if "Ell Hay" has noticed any practical difference in the focal planes and sharpness. If he has not, it rather indicates that he has failed to reach the highest perfection in his Gregorian. If he has, the fact should be noted, as it would tend to elucidate truth, and is of importance to both astronomers and telescopists.

The defects of telescopes and suggestions for removing them, or counteracting them, are of such great importance that too much discussion of them can hardly take place if conducted in the courteous manner so characteristic of "H." and "A. S. L.," and I read every line of theirs and of others who know anything about the instrument with the greatest attention.

"Ell Hay" possibly means John Bird, where he asks for information about John Buck. I fear the search is useless, as I also have gone through the *Leisure Hour* in vain. He may safely write down the account he refers to as a credit to the inventive faculties of the story-teller who took care to be absent when the romance was read, and thus avoided questionings.

I have contemplated trying to grind a mirror for experimental purposes, and shall be glad of advice from those who have experience as to whether a cast disc or a polished plate one will be best. A good many of each must be in use, but little has ever been said as to their merits, excepting, indeed, by a former writer who was interested in their sale. Is the defective annealing of the cast discs any detriment? Would not the internal strains tend to keep the mirror figure good, since they may be said to constitute springs to resist the effects of temperature and pressure? Which is softest and easiest to grind, and which takes the best polish? Is there any difference in freedom from air blebs? I suppose the discs are best cast; but while the polished ones are occasionally advertised in "Ours," I have not seen cast ones offered. I think it would pay the makers of such to advertise them.

In conclusion, I hope the truly delightful letters of "H." will be continued. I have learned very much from them. They are, as far as they have gone, a most perfect elucidation of telescopic optics, and much more interest one than the squabbles that formerly did duty for astronomy. **Hippalus.**

USSHER'S CHRONOLOGY.

[43130.]—THE "F.R.A.S." would seem to imply, on p. 405, that chronologists are "a brotherhood" worthy of no note whatever. We really owe to Archbishop Ussher all the dates in our popular Bible, and all of Abraham's time or later are trustworthy. But his following the modern Jews in all earlier dates was really the work of an ass. With no knowledge of any Chinese or Hindoo dates, anyone could easily find those of the Jews' Genesis were artfully doctored.

I have never questioned the Chinese conjunction of planets in 2446 B.C.; when, according to the Samaritan Genesis, Heber was near his death, and his son Phaleg, born in 2701, and so named because "in his days was the earth divided." The Chinese begin their history just about that year. The lengths of their six or seven first reigns harmonise very well with the generations in Genesis xi.; that is with the LXX. or Samaritan copy—not the Jewish.

Le Verrier's computation of 126 A.D. for the Leonids is not mentioned in G. F. Chambers's or any late astronomy that I can find. The period of the comet is given as 33·25 years, which would give for 15 periods 493·75 years. That is just a year less than the interval from October, 1366, to January, 1866. If Le Verrier reckoned from this 33·25 (and he certainly did from no *longer* one), he would be a

year short in five centuries, and three or four in the time since 126. I should like to see the mathematician who can make 33·25, or 33 29, or 33 28, or 33·27, or 33·26 each suit an encounter in the same year.

E. L. Garbett.

THE MOON AND THE WEATHER.

[43131.]—It is not easy to reply to an argument unless that is clearly stated, and I fail to see any in the quotation given by "A. B. M." (p. 405), from Prof. Angot's work. Nor do I see that the professor has even removed a little bit on one side that persistent "stumbling-block" which "A. B. M." says is "trotted out once more." Why not? That at least is a fact. How do the weather prophets propose to avoid it? Prof. Angot, judging from the quotation given by "A. M. B.," is at least treating the subject scientifically—that is, by research and investigation—work always worthy of respect, even if it leads to nothing; but I note that the professor says, "in the present state of our knowledge it cannot be affirmed that the moon has an influence on weather; but as little can it be denied that such influence may exist." Just so, it may exist; but, so far, I do not think anyone has found a particle of evidence of the existence.

Now, as to what "Glatton" says (p. 406), suppose the influence of the moon can produce "tides" in the atmosphere, how can that be compared with the "ocean tides," the rise and fall of which can be calculated with almost mathematical accuracy months before any given date? The one is a practical certainty, thoroughly ascertained, and even measured; the other has not a single fact to support it—a mere hypothesis. It seems to me that temperature, rainfall, winds, change of weather, &c., have everything to do with the subject when the influence of the moon on the weather is spoken of.

Has not Mr. G. J. Symons shown that for many years the average rainfall of Cumberland has been many times greater than that of Norfolk (for example); how many miles are they apart? Is it not common knowledge that a wind-storm may prevail in one part of this country and be unknown in another? And then what of the whole globe? There is no such vagary in connection with ocean tides. Then as to "aërial" tides, it would be interesting to have the views of balloonists. They often find considerable variety in the "tides" of the atmosphere. Of course, if temperature, rainfall, winds, &c., are not to be considered "weather," it is time that we arrived at what we mean by "weather." The late George Glenny, a well-known gardener, used to declare that changes of the weather generally came with changes of the moon; but when he was shown that the facts were against him, he retorted by saying that he did not mean the actual day set down in the almanac for the change of phase, but two days before and two days afterwards. The belief still hangs about in country districts, and because changes of weather do sometimes come with changes of the moon (so-called), I suppose the old belief will be preserved. By the way, should not the moon have greatest influence on the weather when she is eclipsed?

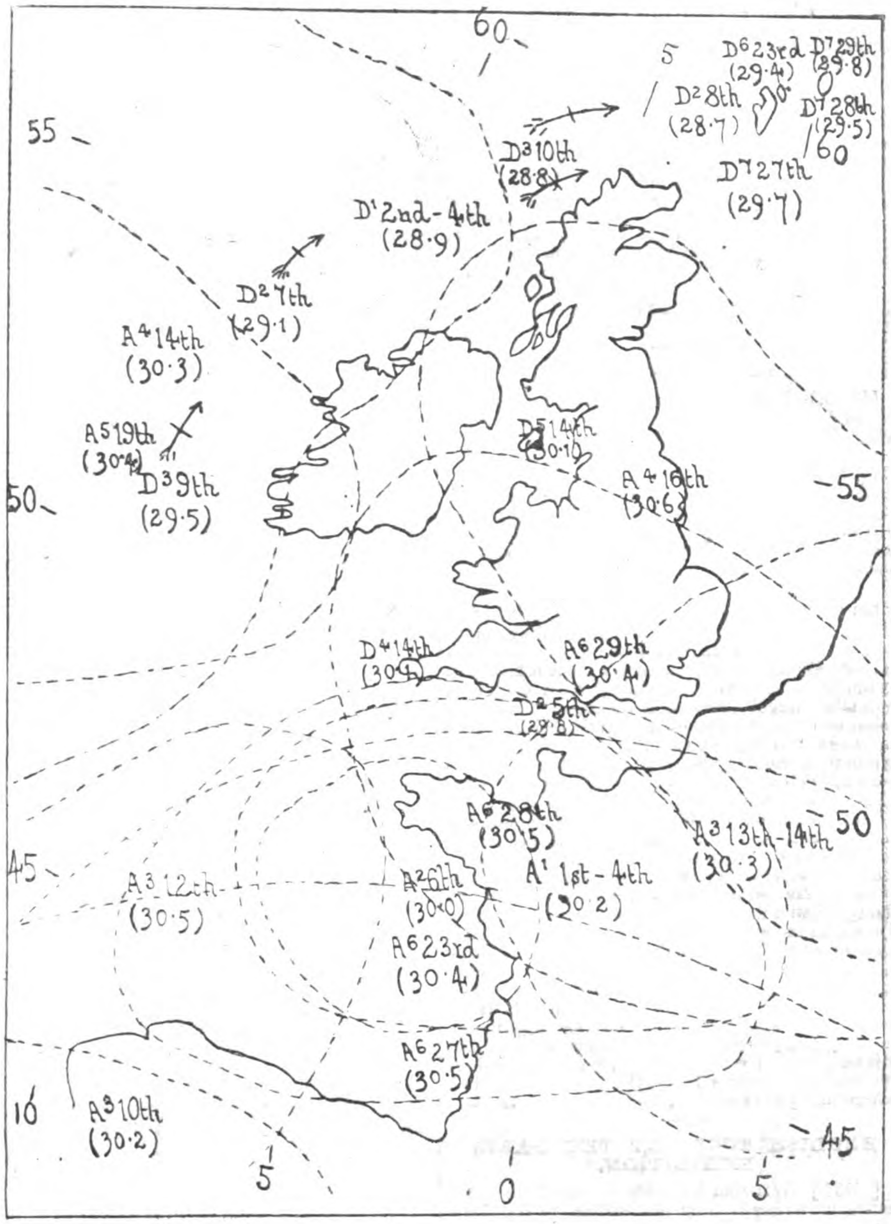
S. R.

THE WEATHER OF THE BRITISH ISLES IN NOVEMBER.

[43132.]—

Date.	Cause.	Effect.
Nov. 1 to 10	A continuous series of depressions passing to the N.W. High pressure to the Southward.	Westerly gales and rain. (Rain fell on every day but one from the 1st to 10th inclusive.)
11 to 15	High pressure to S.E. and S.W. Depression off the N. of Scotland. Shallow secondary disturbances in the Bristol and St. George's Channels.	Fair weather in the S., squally and rainy in the N., and showery in the W.
16 to 20	The anticyclone in the S.E. is joined by another from N.W.	Foggy, gloomy and dull weather generally.
21 to 24	The anticyclones remain stationary.	A continuance of dull weather.
25 to 27	Depression in the far N.E. High pressure to Southward.	Fair, but still rather dull.
28 to 30	Anticyclone covers the S. of England.	Fine in the S.E. of England. Dull elsewhere.

Explanation of Chart.—The anticyclones, or high-pressure systems, are inclosed by the dotted lines; the letter A and the index [5] demonstrate the point of greatest intensity, and the number of the system in relation to the others of the month respectively.



The figures in parenthesis just below show the highest point reached by the barometer in that region. Thus, for example:—A^{6} 27th, with (30·5) just beneath it, indicates that the sixth anticyclone of the month was in the position shown on the 27th, and the highest barometric pressure attained at its centre was 30·5in. The depressions are shown with the letter D, and indices, &c., as before—e.g., D^{3} 9th, with (29·5) below, shows that a depression was situated off the west coast of Ireland on November 9, that is was the third of its kind during the month, and the barometric pressure near the centre of the disturbance was 29·5in. The crossed arrows point the direction in which a depression is travelling.

It will be noticed on reference to the chart that during the first half of the month the depressions all passed to the north-westward of our islands, whilst a zone of continuous high-pressure lay to the southward. It was this which caused the chief peculiarity of the month, which was that the entire rainfall occurred during the first 11 days of the month, after which the high-pressure systems moved over our islands, pushing the depressions away to the far north. Hence, although the month had 1$\frac{3}{4}$in. more than the average rainfall in the South of England, yet it also developed an absolute drought extending over 18 days.

Meteor.

GRINDING AND POLISHING SPECULA.

[43133.]—The photograph of the machine used by Mr. Glass which was reproduced in this journal a week ago (43100) shows very clearly the general arrangement; but it fails to give one a clear idea of the way in which the motion is communicated from one wheel to another. I am familiar, like many others of your readers, I do not doubt, with the construction and details of the various machines used by Sir John Herschel, Lord Rosse, Mr. Lassell, Sir Howard Grubb, and Dr. Common; in fact, I have a machine somewhat similar to the Grubb machine, on a much smaller scale. I also knew something of the Wassell machine as formerly figured and described in this journal. There is one point, however, both in the Wassell machine and in that of Mr. Glass on which I think it would be very satisfactory if some little light were thrown. The point I refer to is what is termed in both cases the "oval wheel." If Mr. Smith, who sent you the photograph of Mr. Glass's machine, would be so good as to give a rough pen-and-ink sketch or drawing of the oval wheel, and the manner in which the various motions and speeds are communicated to it and the other wheels, I, for one, should be very much obliged. From the photograph, it is not possible to make out any of these.

Speculum.

SPLICING.

[43134.]—Mr. Hudson (letter 43113) hopes that I am not going to "slip through" (as he rather nastily puts it) the articles on "Millwright's Work" "without treating the matter of splicing in as exhaustive a manner as he has done the jointing of belts. The reason why I did not illustrate splicing was because I had done so in "Fitting," and had no wish to lay myself open to the charge of repeating myself. The usual method was given correctly in that series.

As regards "best practice," who would care to take the responsibility of deciding that, except in general terms? Mr. Hudson correctly quotes me to the effect that "the splice is carried over a length of 4ft. or 5ft." That was "good practice" in 1892, when the passage was written, and I wrote it because that length was adopted in 1in. ropes, which I then knew running rapidly, and wearing well. Then, in "Millwright's Work" I say: "Not less than 6ft. to 12ft.," which gives increase in length, the longer being, of course, for the larger ropes. That is true in 1899, because the growing

tendency since 1892 has been to increase the length of splice. Then, finally, I give "a firm's table, which runs from 9ft. to 20ft." That is the table of one of the leading firms in America, who have made a speciality of rope-driving, and whose "best practice" is, therefore, suitably compared with English. There is nothing inconsistent in recording these developments.

As regards wire ropes, the splices for these are usually and properly made at the manufacturers. Concerning the splices of cotton ropes, there is a great deal yet untouched in "Millwright's Work," without taking up space for splicing; and which, if it is necessary to treat and illustrate again, should be done in an article or letter devoted specially to it. I will, however, with the Editor's permission, promise Mr. Hudson to bear this in mind.

J. H.

POISON IN FISH.

[43135.]—I REGRET the mistake on my part pointed out by "Glatton." The fish was a haddock; otherwise all that was stated was strictly accurate, and it would be of interest to be favoured with some explanation, if any can be suggested. I did not think it necessary to take up more space by mentioning that the two members of the family who suffered had each eaten a portion of another fish before they each took a little of that which is believed to have caused the illness.

L. C.

[43136.]—THE question propounded by "L. C." (p. 383) can apparently only be answered by guessing; but fish do sometimes disagree with people—notably mackerel. If the suspected fish had been examined by an expert, probably some useful information might have been obtained. Whiting, soles, plaice, and haddock are invalids' fish, and as to what "Glatton" (p. 407) says about "one whiting is usually not more than enough for one person," it is well that he put "usually." I have frequently bought whiting during this past three years, several of which weighed two pounds and more when cleaned. The whiting (Merlangus vulgaris) is a very voracious fish, and sometimes reaches a weight of three or four pounds. On one occasion my wife bought a whiting which she thought had a fine roe; but that turned out to be a fish which the whiting had swallowed. The greater number of whiting brought to London have, like haddocks, been opened and the viscera removed; for, while they are a delicate-fleshed fish, they soon go wrong when sent to market "round." Haddocks are sometimes passed off for whiting by scraping and by removing the "thumb-mark," but it is easy to certify to a whiting, for it has a black spot on the upper side of the pectoral fin, just where that joins the body.

S. R.

ENGLISH TOOLS AT THE PARIS EXHIBITION.

[43137.]—WE wish to notify that we have sent a notice of withdrawal of our exhibit to the Commissioners of the Paris Exposition of next year, where we had intended to have made a fine display of English-made tools.

The present ill-feeling in France against anything English is being fostered, we have noticed, by some of the most respectable French papers, and exhibitors have unfortunately no guarantee that this discord will not become accentuated as the time for opening approaches. This may pass quietly away; but exhibitors who have an interest at stake have *not time to hesitate*, as exhibits should be now in active course of preparation.

The value of the Exposition to many English houses will depend largely upon a good British attendance, and we feel that such a conspicuous want of welcome will seriously interfere with the number of British visitors. It is possible to be too easily alarmed at the trend of circumstances that may seem to affect the success of this exhibition; but, although the proposed boycott at the time of the Dreyfus decision was properly considered to signify nothing but a newspaper scare, there is now an element of uncertainty that cannot be ignored by those who have relied upon a good British and Colonial attendance amongst the visitors.

We mention this in extenuation of those whose interest in this matter is identical with our own, and anticipate that the same considerations will not influence those whose object it is to cultivate Continental sales, and extend the reputation of other English goods in this market.

R. Melhuish, Sons, and Co.

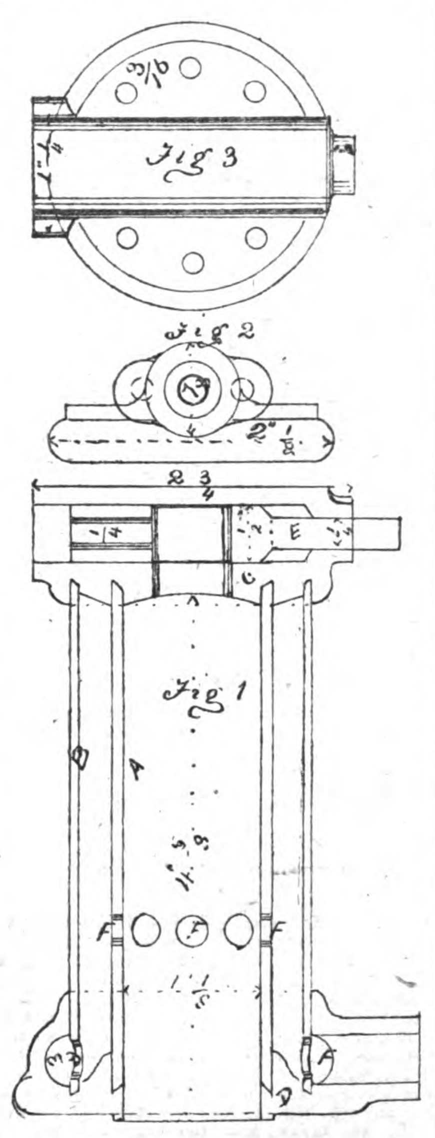
HOW TO BUILD A LIGHT ENGINE FOR VARIOUS PURPOSES.

[43138.]—IT is said that there is a time for everything if we will only wait. As I think, the time has arrived when a scheme I have had in my head may be turned to account. Take things all round, there is nothing new in it; but there are a few points thrown together that have been discarded in the past, but are now taken up to advantage, and, instead of retrograding, is practically an advance. In the small sixties I was called upon to manipulate upon a steam-hammer, and in overhauling it I came across an arrangement for rapid exhaust. A thought struck me at the time that it could be utilised for a single-acting engine. Well, of course, the steam-hammer was such in one sense. I committed it to paper, and intended to turn it to account for a relative of mine, who had been in the Crimean and China wars, and, as I thought, had come home to settle down. But there was no material that I knew of that would serve my purpose then. Some time after I was engaged upon the Palliser experiments, when I saw an account of guns—i.e., old cast-iron ordnance—being reinforced by the lining of them with solid drawn-steel tubes. I then said to myself, "The very thing for those engines; I would like to see a sample." Some



time after I was shown a sample by an old shipmate, and they far exceeded my expectations. They were very clean and bright inside and out, and true. He then told me that it was the outcome of an old shopmate of ours, I believe. At any rate, my relative was not happy at home, and we lost the run of him for some time, when we had news that he died at Aden, so the affair was shelved, but not to rest, because at different times I have worked out in rough sketches engines various. Now some of these, with the Editor's permission, I intend make presentable for your consideration, and I have not the least doubt but what some of you that can handle tools will find it an easy task to furnish you with what you have long desired. There is novelty in them, not a great deal of work, and not difficult work, and a useful little engine can be made in a 4in. centre lathe. The pattern making is very trifling—it is a trunk piston rotary valve, steam-jacketed or water-jacketed as the case may be, whether you fit it up for steam, gasoline, oil, or gas. You will see that the principle by alteration of valves can be turned to account for either. The trunk engines and rotary valves, as well as mushroom valves, are very old acquaintances, and single-acting engines trunk pistons I can recollect as long ago as 36 years when a three-cylinder trunk piston engine was at work at an alkali works, and I believe the maker's name was "Ramsden," "Ransome," "Ramsey," or some such name as that. It was driving a pair of large-edge runners, granite, and six stirrers in large vats; and although the cold shoulder has been given to single-acting engines, they have not only come to the fore, but, instead, we have the cycle of one in four strokes, doing good work, and quadruple expansion to the fore. The following sketch will represent a cylinder built of material now to be found in abundance. A is a piece of steel tube solid drawn, B brass triblet tube. The ends may be made of any of the bronzes or malleable cast iron—(that is, those marked C and D), E, the valve, of phosphor-bronze, brass, hard-drawn rod Delta metal, or any of the bronzes, but best made of the hard rod. F F F F are the exhaust; it is put together with six $\frac{3}{16}$ bolts—large ones between A and B.

Jack of All Trades.

VIBRATION OF ETHER.

[43139.]—THE matter pervading our Solar System, ether, is capable of transmitting the vibration which we know as light. Seeing the disturbances taking place on some of the planets, and their movements in that same medium, it is not unreasonable to imagine that these vibrations, quicker or slower than those producing light, may be transmitted to, and influence at least, the smaller bodies such as comets, Leonids, &c. They might be influenced either by being attracted, repulsed, forwarded, or retarded in their orbits. That would, of course, depend upon the form of the wave; crest forward and trough following would repulse; the reverse, attract. I should like the opinion of some of the readers of "Ours" on this subject.

J. H. Schucht.

PEAT.

[43140.]—I AM just now living almost upon a layer of that curious substance peat, which has made me want to find out just what it is, and how it is formed. This has led into the subject of coal, of which peat is a stage in the decomposition of cellulose. And thus a vast mine of information is worked on, and is still unworked. For the change of cellulose, or leaves and the like, into anthracite coal through peat is possible. They have been for two years opening out a park in Newark, New Jersey, and, as part of it is only a quarter of a mile from my house, I have visited it continually. I have thus been enabled to watch the digging, and to get some very nice fossils also. The wood is common, in the shape of logs over 6ft. long, cedar mostly, and these I have deposited in the collection of the Newark High School, where Prof. George Sonn, who has collected along with me, will have charge of them.

I find that the etymology of peat is doubtful. Skeat, we are told, considers the true form to be beat, from its being used to beet or mend the fire, from the middle English *belen*, to replenish the fire. At all events it must have been used to build fires where wood was scarce, and long before coal was used—for that is of comparatively modern use.

In most geological books it is said to be formed from sphagnum or similar water moss, is decomposed, and thus formed peat. But leaves also, not of water-moss, can form peat, when immersed in water and permitted to decay. And in this way coal is formed undoubtedly. And this peat, which I have examined in Newark, is formed of the roots of different water-plants, which, decomposing in standing water, undergo decomposition. On examination by means of the microscope, it is found to contain very little inorganic or mineral matter, this being made up of sponge spicules, the silicious spicules of *Spongia lacustris*, L. Mixed with these are now and then pustilles, or loricæ, as they are called, of fresh-water bacillaria; *Navicula major*, F. T. K., being by far the most common. In fact, this form is cosmopolitan and present everywhere, and in fresh, brackish, and even in salt-water. It is the most common of bacillaria when they are common. But the organic matter is present as a brown substance, without any definite form to indicate the plants from which it was derived; being without cellulose or any other substance which can make the form of the cell from which it was derived.

But the fossils that are the largest in the peat are trees, the stumps of which often are 6ft. long by 15in. across at the butt. Several of these have been taken out, and they are, for the most part, white cedar (*Cupressus thyoides*). There are branches of several other trees, and in one place a pestle of stone has been found. The wood is mostly very pliable, but can be cut into sections for the microscope.

And this brings me to speak of the so-called pine barrens which cover a large amount of the State in the Southern counties. They are made up of the remains of land plants, but often are now beneath the tide of salt water. They show the land is now going down rapidly, although it has been immersed before. The peat is now over 2ft. to 6ft. thick, though in Newark it is not a foot thick. Beneath

this is a layer of blue clay oftentimes very bacillarious, and in some places pure bacillarian, as at Weequackhic Lake; it is there 1ft. thick. Beneath all is the gravel of the Glacial moraine often markedly situated.

We can thus see the formation of the iceberg period, and trace the bacillaria, as well as at Mount St. Elias, on the Pacific coast. It is easy to see how the peat accummulated. At first the growth was higher than it is now, and colder weather prevailed; in fact, snow fell. This accumulated and packed to form ice. Then came the Glacial period, and the ice was heavy, and the ground sank beneath it until it became warmer. Then the ice broke up, and there came the Iceberg period, and bacillaria were common in the water. The icebergs floated off at the edge of the ice, and moved away from several points. One was in the north-west, and the icebergs floated away to the south-east, over New Jersey, bringing with it the logs of the forest, white cedar mostly, and deposited it in the valleys which run across the country, and one or more are in Newark. One of them is where they are laying out a park, and where they are digging Clark's pond 4ft. lower, and where the fossils were found. The water that formed was impregnated with vegetable matter. This formed the peat on the bottom, which was of clay—blue clay. At last this almost dried up, and left the mass of peat there. This is the way the peat came.

Arthur M. Edwards, M.D., F.L.S.

23, Belleville-ave., Newark, N.J.

FROM AN OLD FRIEND.

[43141.]—MY best thanks for the four Oct. numbers of the ENGLISH MECHANIC. Long before you get this, they will have given much pleasure to many of the soldiers in this lonely camp. I hope, also, that those which went to South Africa will give pleasure there, too. Oh, dear me, I believe I am one of your oldest subscribers. I began over thirty years ago. What changes! I wonder if you are the same? The next time I am on leave, and in town, I shall try and see you.

T. H. Foulkes, M.A.,
Chaplain to H.M. Forces.

British Camp, Kandia, Crete.

[Yes; just the same!—ED.]

SODOM DESTROYED BY THE LEONIDS.

[43142.]—MR. GARBETT again appears with his vapid assumptions. The above is not a suitable theme for discussion in a journal dealing with mechanical and scientific subjects. The observed facts of science show that a concentrated bombardment of Leonids in one isolated spot could never have taken place. The region of the Dead Sea, as it is now, has the same geological aspect and condition as it was countless thousands of years before the evolution of mankind upon the face of the Earth, so all chronological references are worthless, as they are mere suppositions and legends of men who knew nothing of such matters. Within the immense lapse of time after these geological disturbances there have been no cities or dwellings on the site of the Dead Sea, for no inhabitants could have existed there.

I have travelled on the borders of the Dead Sea, and it is quite apparent that the formation is due to a rupture and displacement before the crust of the earth had arrived at a state of quiescence and equilibrium. No living thing found a place on this desolate spot. So great was the upheaval that in one range on the east shore huge masses of rock have been tossed up. The well-defined stratifications of clear red and yellow streaks appear in perpendicular, inclined, or even inverted positions. We would have taken a photograph of the scene if we could have got our camera to bear upon it. The surface of the water was formerly at a higher level than at present, but has become lower by evaporation. This is now balanced by the constant inflow of the Jordan, the whole torrent of which is dissipated as vapour, for there is no outlet from the lake. In places the shore is so incrusted with salt as to resemble snow-drifts. Cakes of it were picked up by our mule-men for sale at our further destination. We found the waters of the Jordan so far salt that we had a difficulty in washing our negative-plates on account of a deposit of chloride of silver (these were in the wet-collodion days), which required an after-treatment to get rid of the fogging of the pictures, so the saltness of the lake is increasing. The level of the Dead Sea surface is over 1,300ft. below that of the Mediterranean, and the heat scarcely endurable. At sundown there are usually tremendous wind storms rushing down through the gorges of the hillsides, caused by the hot-air ascending, and the colder air from above taking its place. There is no vegetation for man or his flocks, and no community could ever have resided there. There is no tangible evidence by modern teaching to show that such anomalies in the definite conditions and order of this world's progress could ever have existed as miracles.

F. H. Wenham.

NATURAL HISTORY STORIES.

[43143.]—AMONGST the natural history stories recently published, I think this should find a place: "An employé of some timber merchants, while engaged in felling trees at Glen Roy, Lonan, Isle of Man, on striking a tree with his axe, was greatly surprised to find that he had hit upon a nest of bees. As soon as an opening was made, the bees issued forth, and the exodus continued for about two hours. Afterwards it was found that the nest contained an immense quantity of honey, and although some ran waste, over 70lb. weight was secured." I can understand that bees do make their "home" in the trunks of hollow trees; but I want to know what the bees did when they were disturbed by that axe, especially as they were two hours completing their "exodus"?

S. S.

STENCILS FOR SHADOWS.

[43144.]—THE plate inclosed is a copy from a paper one that has been in our family for a great number of years, and has been kept secret. I do

not know if ever you saw anything like it. You will see whom it represents on holding it against a white wall by gaslight. The shadow is good. I thought it could be put into print, for a great many people, I am sure, would like to have one. The drawing is half-size of the plate, which is simply cut out in thin sheet iron.

John Bywater.

3, Reedham-st., Choumert-rd., Peckham, S.E.

THE Russian Government are elaborating a scheme for the systematic colonisation of the northern coastlands of Siberia, and for the establishment in that region of an authoritative system of government control.

Classification of British Guns.—Generally speaking, all guns of classes used in the field are named from the weight of their projectile (approximately), the weight of the gun being also mentioned if further distinction is required. The one exception is the 2·5in. gun, which is made in two parts, to screw together, and is intended for mountain service. It is really a 7-pounder gun, but is distinguished by the diameter of its bore for a special reason. Thus, we have the 12-pounder of 6cwt., the gun with which the Royal Horse Artillery is generally armed, firing a shell $12\frac{1}{2}$lb. in weight, with a charge of 12oz. 7 drachms of cordite, and the 15-pounder, with which Field Batteries are equipped, weighing about 7cwt., and firing a shell of between 14lb. and 15lb., with a cordite charge of 15oz. 12 drachms. Howitzers (which are short pieces, relatively to the diameter of the bore, intended for firing heavy shells, with comparatively low velocities, for the destruction of buildings and field or other works) and guns over 3in. or 4in. in calibre are distinguished by their calibre or diameter of bore, with the addition, when necessary, of the weight of gun. Thus we have the 5in. howitzer (of which a battery has just reached South Africa), which weighs 9cwt., and throws a shell (filled with Lyddite) weighing 50lb., the firing charge being about $\frac{3}{4}$lb. of cordite. We have guns varying in calibre from 4in. up to 17·72in. Speaking generally, the weights of projectile for the following guns are about those stated against each, but they vary somewhat, according to the nature of the projectile, and, in some cases, the pattern of the gun: 4·7in., 20lb.; 6in. (gun), 100lb.; howitzer, 118lb.; 9·2in. (22 to 27 tons), 380lb.; 12in., varying from 45 to 47 tons (in very general use in the Navy), 714lb.; or a late pattern, 850lb.; 16·25in. (111-ton gun), 1,800lb.; 17·72in., 2,000lb. Except the last, all the guns mentioned are breechloaders.

REPLIES TO QUERIES.

*** *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

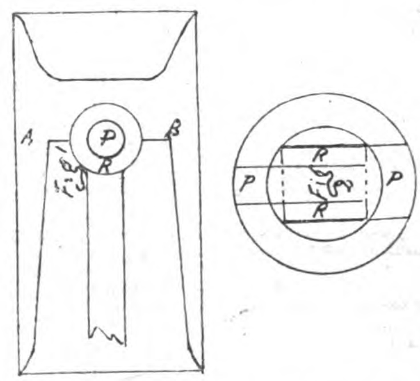
[96811.]—**Converting Objective.**—The water immersion would not give a sharp image when used with oil, without some correction. If made on modern lines, the front lens could be adjusted, or a new one formulated. For the objective to perform, the front lens might probably want to go closer to the correcting lenses than they would allow—that is, it would touch the next lens before a critical image could be formed. It should not cost much, but opticians capable of doing it are few and far between. Cedar oil is now used universally; its refractive index, 1·51 about, is very near many of the crowns used in objective making. We use ourselves glycerine, with a chemical salt dissolved to index of refraction whilst adjusting the front lens, until it is permanently fixed by running a minute ledge of metal over the edge of it, and then finally test for cedar oil.

Bognor. ENGLISH OBJECTIVE CO.

[96818.]—**Square Thread (U.Q.)**—I do not think that you will find anything better than taps. If you have a quantity of holes to tap, get three taps made, the diameter at the bottom of the thread in each case to be $\frac{1}{4}$in., while the largest diameter to be, say, $\frac{19}{64}$in., $\frac{11}{32}$in., and $\frac{3}{8}$in. respectively; the end of the taps to be tapered for about $\frac{3}{8}$in. Thus each tap will get a fair share of the work, and a little care will insure freedom from broken taps.

CLYTIE.

[96864.]—**Knocking in Gas-Engine.**—I do not know the construction of your piston, but it should be as sketch, and a good knuckle-joint made as shown. There is very little tug on your piston; it is all thrust. You have very little stuff to play with, and don't bore out to bush it, but lap it out true, and make a new pin, and either make a bush, as I have said, or get a piece of solid-drawn tube—i.e., steel—and make a bush, not forgetting the holes in



it. Fig. 1 is section through centre of length R, P pin. Fig. 2 is section of piston through A B, Fig. 1. R, eye of rod, and P P pin. That is as it should be fitted, a good butt knuckle-joint.

JACK OF ALL TRADES.

[96891.]—**Sun Views by Projection.**—My quotation from Proctor's "Half-Hours" was perfectly correct, it is from the 12th edition, p. 104. Will Mr. Wadsworth kindly tell me to what extent he stops his $8\frac{1}{2}$ mirror? My o.g. is 4in.

Masulipatam. E. G. R.

[96987.]—**Series (U.Q.)**—This query, on p 282, Nov. 3, has, I see, got into the "U.Q." column. The series is—

$$y = 1 + x + \frac{x^2}{1^2 . 2^2} + \frac{x^3}{1^2 . 2^2 . 3^2} + \frac{x^4}{1^2 . 2^2 . 3^2 . 4^2} + \&c.$$

It is required to find if there is any exact expression which will give y in terms of x. Referring to Boole's "Differential Equations," chapter xvii., where the symbolical method of working is explained, I find the differential equation of the above series is—

$$x \frac{d^2 y}{d x^2} + \frac{d y}{d x} - y = 0.$$

This can be tested by performing the operations indicated on a few terms of the series, which, when the results are added, gives the series—

$$y = 1 + \frac{(2 + 2) x}{1^2 . 2^2} + \frac{(3 + 2 . 3) x^2}{1^2 . 2^2 . 3^2} + \frac{(4 + 3 . 4) x^3}{1^2 . 2^2 . 3^2 . 4^2} + \&c.,$$

which is the same as the given series, as all the numerators are exact squares, and they cancel the

last square number in the denominators. Now, if there were an exact expression for y, the diff. equation given above would be integrable; but it can be proved that it is not exactly integrable, so that there is no exact expression for y.

Bath. M.I.C.E.

[97007.]—**Boat.**—What is meant by the "section of wood" for this boat? The kind of wood may be anything the querist likes, except elm, which will, however, do for the keel if the boat is kept in water always. He can use yellow pine or oak—the latter for preference. PUTNEY.

[97011.]—**Acetylene Generator.**—It seems to me that this querist should see the acetylene generators illustrated in back numbers, and, by the way, mostly patented. B. C.

[97023.]—**Engraving Tools.**—What is the meaning of "lead lessened about ¼in.," "pressed into cut," in the reply under this head on p. 324? A little explanation seems necessary. METOPS.

[97031.]—**Enamelling Oven.**—The querist should look up his back volumes for an enamelling oven. The iron may be only ⅛in. thick; but it is better to use ¼in. The burners (Bunsen) are usually underneath, and the oven, being surrounded by brickwork, the hot air passes all round it. A temperature of 300° to 350° Fahr. is required; but it depends on the enamel. V. P.

[97038.]—**Colouring Oil.**—Does it not occur to the querist that paraffin means "without affinity," and that therefore he will have some difficulty in colouring the oil? H. C.

[97044.]—**Accumulators.**—If the querist will turn up his back numbers he will find full instructions for making accumulators; but as to the rest of the query he must say what quantity of current will be required before sizes, &c., can be given. M. L. D.

[97050.]—**Electric Lighting.**—It is scarcely likely that the old-fashioned atmospheric gas-engine has ever been used to drive dynamos. It is not sufficiently steady in running. M. L. D.

[97149.]—**Manchester Dynamo.**—To MR. BOTTONE.—There is no mistake in the figures except 5½in. on each core ought to read 5½lb. on each core, and if Mr. Bottone reads my query again he will see that I have put my fields in parallel, and given him the result last week. Many thanks for his reply. TRY AGAIN.

[97198.]—**Screw Gear-Wheels.**—My inquiry last week has a mistake in it. I forgot to fill in the size of wheel where the printer has put the note of interrogation. It ought to be 4½in. diameter. J. A. C.

[97200.]—**Feed Pumps: Steam Launch.**—Best way to reduce speed of pumps would be to use spur gearing two to one ratio. Mount wheel in an eccentric bearing similar to back gear of lathe; it can then be thrown out of gear, and is convenient for examining pumps when running. If you want to adopt chain, then use Hans Renolds with inverted teeth, which will run on spur gear wheels, and forms a flexible rack; it works very sweetly. MONTY.

[97206.]—**Spokes.**—The construction of a cart-wheel is based on a sound scientific principle. When one wheel of a cart, through an uneven road, becomes lower than the other, it is obvious that this lower wheel has to bear a much greater weight than the higher one. To meet this it will be seen that the lower wheel becomes stronger than the higher wheel, simply from the fact of its spokes approaching nearer to the upright position; whilst in the normal position of a cart, the weight being equally divided, individual strength of wheel is not required. Were wheels built with the rims in the same plane as the nave, they would be weakest just at the time when the greatest individual strength was required, and strongest in the upright position when great individual strength of wheel was not required on account of there being two to bear the load. F. FITZPATRICK.

[97219.]—**Rope Drive.**—I should be obliged if "Monty," who kindly replied to my query, would let me know where I can obtain the Dick's belt? I advertise my address in this number. I should have thought a belt unsuitable when so short, there being only about 2½ft. from centre to centre of pulleys. The motor has a tension screw, however, to take up slack in belt. I cannot increase the length, as the apparatus is in a motor car.

Belfast. J. BROWN.

[97219.]—**Rope Drive.**—For "driver" read "drives." Typographical errors in many of the answers are apparent to a thinking reader. Read articles on "Millwright's Work" now appearing, which I had not read when replying. These give all the information required on rope driving, besides illustrating same. MONTY.

[97235.]—**Melting Old Brass.**—If you use all scrap brass, you will find the castings porous and defective; better use half-scrap and half-new metal. There should be no difficulty in melting in a smith's fire, as I have done it many times. You will get the best possible sand for casting brass at about 10s. per ton, plus carriage, so do not be tempted to pay fancy prices for doubtful compounds. CLYTIE.

[97235.]—**Melting Old Brass.**—If you think you can get 1,650°, the melting-point of brass, from a smithy fire, why, yes. You might try a small piece in a crucible first, but I think it doubtful; however, it is worth a trial. Otherwise, you will require a brass founder's furnace—no flux.

REGENT'S PARK.

[97235.]—**Melting Old Brass.**—There should be no difficulty in melting brass on an ordinary smith's fire. Get a proper crucible for the job, then make a fire with hard coke, and after it has blown up nice and bright bury the pot well down in the fire and heat up very gently, so as not to burn the bottom out of the pot. The metal will not require anything mixed with it to make it melt.

E. W. FRASER.

[97235.]—**Melting Old Brass.**—Old brass may be melted on a smith's fire in a small crucible, using coke. G. BOUSFIELD.

[97236.]—**Chimes for Clocks.**—Probably the correct note for the hour-bell of a Westminster chime is an octave below the third note of the quarters, No. 1 being the highest note, the chime reading B, A, G, D, and hour, G octave; but in most church clocks where a ringing peal of eight bells is used, the quarters are taken on the second, third, fourth, and seventh, and the hour on the eighth bell. In house quarter-chime clocks there is usually no musical relation at all between the chime bells and the hour bell, the matter is left purely to chance, and no one appears to notice any defect. "Cambridge" and "Westminster" chimes are the same. Eight-bell chimes are sometimes erroneously called "Cambridge" chimes, and these (eight-bell chimes) are taken on the octave anyhow, according to fancy, the hour being sometimes on the eighth bell, and sometimes on another having no musical relation to any of them. F. J. G.

[97236.]—**Chimes.**—The obvious note for the hour-bell is surely the tonic, or "key-note," of the scale in which the chimes have been playing. No other note can satisfy the ear as final. If the chimes were in G major, to end on C would be to end on the subdominant of the scale which the chimes had impressed on the ear; *that* would be extremely unsatisfying. At Croydon the chimes at the town-hall are in one key and the clock strikes on a note entirely out of it, or else utterly out of tune—the effect is enough to drive one frantic.

Farleigh Rectory. F. BENNETT.

[97237.]—**Jewish Calendar.**—The modern Jews always observe every feast on two successive days, to be certain of keeping the right day. Now, if this was already done in our Lord's time, it shows there is no contradiction between the last Gospel and the three earlier. Christ celebrated the supper on lamb the Thursday before ordering His own supper of bread and wine; but many, the following day, would not enter Pilate's hall, meaning to eat the lamb that Friday afternoon, when Christ was on the cross. The year was not, as "Studens" fancies, either 30 or 31 A.D., but 33. It was the fourth year of the 202nd Olympiad, in which Phlegon's book of "Phenomena," now lost, dated the wonderful eclipse of the sun at noon, and earthquakes. The same evening was an eclipse of the moon, visible at Jerusalem. The darkening of both sun and moon the same day had been foretold in Joel ii. 21, which St. Peter quoted in Acts ii. 20. Amos also had foretold that it should be a feast day, viii. 9; and Zechariah, xiv. 8, that it should be "one day which is known to the Lord, not day nor night, but at evening time it shall be light." The Jews, using a lunar calendar, must have known well that a natural solar eclipse could happen on no day but the last of their month, and that a solar and lunar one the same day must be miraculous. In old crucifixes we find the sun totally dark, and the moon partially dark, on each side. Gentiles, not keeping lunar months, were unaware of this. Seneca, who was born in Spain, was only a boy at the time, and those about him may have thought it a natural solar eclipse. But Pliny dishonestly ignored the darkness in Pilate's time, because of the use he knew Christians to make of it; and made a great wonder of that which was said to have followed Cæsar's death, near a century earlier. There were annals at Rome, like a modern newspaper, that told of the darkness in Pilate's time, and the Early Christian fathers directed inquirers to them. E. L. GARBETT.

[97237.]—**Jewish Calendar.**—"Studens" can obtain all the information he wants by writing to the Time Observatory, Wanstead, E. As B.C. and A.D. years are not made by the sun, they have no existence save by legislative enactments. The first day of Nisan in the Crucifixion year was Friday. The year was 4029 A.M. by solar and lunar motion. Hence the 14th was Thursday and the 15th (Passover Day) was Friday. J. B. DIMBLEBY.

[97238.]—**Truing Emery Wheels.**—As a rule, a bit of hard cast-iron will do, or an old file used edgeways; but if a certain face has to be given to the edge of the wheel a bort tool would probably be necessary. METOPS.

[97238.]—**Truing Emery Wheels.**—To G. BOUSFIELD.—Small emery wheels, or grinders, are commonly trued up by a piece of carbide, or black diamond, set in the end of a metal rod in the usual way. For the larger wheels I have used the following method:—Take a rod of some tough wood, about 10in. long and less than 1in. square, near one end drive in a common wire nail, nail transversely, with a stop behind, to prevent it from driving back. This is used like a small pickaxe. While rotating in the lathe mark the high places on the emery wheel with a piece of chalk, and break them down with the pick till they are effaced. Soft iron for the pick acts far more effectively than hard steel.

F. H. WENHAM.

[97238.]—**Truing Emery Wheels.**—The emery-wheels should be put upon a mandrel in the lathe, and very light cuts taken over them with a diamond mounted so as to be held in the slide-rest. Run slowly, or you will lose the diamond. If you have neither a diamond nor one of those hardened steel wheels which are sold for truing emery-wheels, the following may help:—A short time ago a friend of mine had the job to turn and bore out some 18in. by 2in. emery-wheels of good quality and coarse grain. He was told that the firm would not go to the expense of a diamond for boring them out, so he mounted one of the wheels on the face-plate of a 12in. lathe, ran the slowest possible speed (back gear in), and let a gas-flame play on the wheel till it was too hot to handle comfortably. Then he got some old three-cornered files, and put one in the slide-rest with one of the sides uppermost, thus making a cutting-edge of a sort. By this means he cut a recess 8in. by ⅜in. both sides of the wheel, breaking a bit off the file when it got ground away too badly to cut. It is a rather slow job. Last, but by no means least, is the terrific shriek the wheels set up when the cut comes on, and which, in the case referred to, defied all efforts to stop it. It was heard far and away above the rattle of nearly a hundred machine-tools, and was the cause of much profanity amongst those near the lathe. E. W. FRASER.

[97236.]—**Truing Emery Wheels.**—They are usually turned up with one of the numerous emery dressers, which consist of about six discs held in a holder, the edges of the discs being either serrated or wavy. They cost from 2s. 6d. to 5s. each, and must be used when the wheel is running at its usual speed. A piece of black diamond is much better, but the wheel should only run at a surface speed of about 100ft. per minute. CLYTIE.

[97241.]—**Small Spark Coil.**—To MR. BOTTONE.—Length of iron wire core 5in., diameter ⅝in., gauge No. 22; diameter of heads, 2in. Primary, two layers No. 24 silk, about 3oz.; secondary, 6oz. No. 36 silk; condenser, 50 sheets tinfoil, 2in. by 3in., interleaved with paraffined paper. Mica not much use. One-pint chromic-acid cell, or one single cell accumulator will work this coil well.

S. BOTTONE.

[97242.]—**Plating Dynamo.**—You must not expect to do much in the way of plating with so small a machine. Wire on armature, 3oz. No. 18; wire on field, 2lb. No. 20. Connect up in shunt.

S. BOTTONE.

[97244.]—**Grammaphone Experiment.**—I saw it stated in the "E.M." some two or three months ago that the same experiment which you describe in query had been successfully performed. Although you will get double the volume of sound, as far as regards the music or speech, I have no doubt but what the grating noise of the needle and record will also be increased in some proportion. I do not think any ear would be able to detect any undulations, with the needle at such a short distance as ¼in. apart, as the pitch of the note produced by each needle will be practically identical. If you are able to make your own records, you might try the following experiment:—Instead of placing the needles of each diaphragm one behind the other, fix them side by side, so that the line forming the two points coincides with a diameter of the disc, and fix them about one groove apart. Now, supposing you have a duet of voices or instruments to be reproduced, allow each voice or instrument to its own diaphragm. With quartettes, two of the parts might be allotted to each diaphragm, or, if experience taught otherwise, the melody part might be reproduced by the one diaphragm, and the remaining three parts by the other, also similarly with bands, &c. This arrangement of twin needles would shorten the performance of the songs, &c.; but, if necessary, larger discs and turn-tables could be made. I think this arrangement would not only double the volume of sound, but what is more important, would improve the quality or timbre. I beg respectfully to commend the above to the notice of the Gramophone Co. T. D.

Gateshead.

[97246.]—**Air-Heating.**—For churches and large public rooms allow 5ft., for schools and lecture rooms 7ft., for dwellings 14ft., and for greenhouses 35ft. of 4in. pipe per 1,000c.ft. of space, to maintain the temperatures required in such structures. If pipes are in, channels will require 20 per cent. more to give same result.
161, Albion-road, N. A. CLARKE.

[97246.]—**Air-Heating.**—I do not know of experiments on heating air by plates in actual contact with fire which would be necessary in order to get as much as 500° Fahr. Why is such an excessive temperature required? Rules for surfaces of steam and hot-water pipes to heat air to more moderate temperatures, say 70°, will be found on p. 337, Vol. LXIII. *Engineering*, together with tabulated results of experiments. GLATTON.

[97247.]—**Static Machines for X-Ray Work.**—To "SCALPEL."—Wimshurst machines of sizes up to 24 plates of 38in. diameter may very well be worked by hand. 24in. plates, if all is rightly designed, will give about 11in. spark. A machine with 8 plates of 24in. diameter will work almost any tube. Still a larger machine will naturally give more electricity, and require less time for an exposure. The machine which photographed the thorax had 12 plates of 2ft. 4in. diameter. The machines are made by many makers; but examine and satisfy yourself with the workmanship and the design before buying. J. W.

[97247.]—**Static Machines for X-ray Work.**—(1) Yes, easily. The length of spark depends on the number of sectors, and the height to which the jars are coated. The machine should give 10in. to 12in. sparks. (2) Procure a bianodic tube of 9in. length, exhausted to 2 millimeters on the gauge. (3) Dr. Monell's machine is an eight-plate 32in. machine. We supply these. (4) Yes; my "Radiography" and Dr. Monell's "Electro-therapeutics." S. BOTTONE.

[97248.]—**Compressed Gas.**—Probably Hurst and Lloyd, of High Holborn, W.C., engineers, would be a good firm to apply to. I take it, compressed air and gas are very much alike. If so, a perusal of F. Richards on compressed air may be handy reference—of Chapman and Hall, London.
REGENT'S PARK.

[97249.]—**Vertical Boiler.**—The practice in the British Navy is to fill the boilers to the top with distilled water when laid up. Another plan is to dry the boiler with a small fire, put an iron tray or box of quicklime inside and shut all valves, manholes, &c., airtight. GLATTON.

[97249.]—**Vertical Boiler.**—Corrosion may be prevented by adding about 5lb. of common soda to every 10c.ft. of feed-water used, or by metalically connecting rolled zinc to the inside of boiler. If a large one, the zinc must be connected in different places, so that the zinc is within 6ft. of any portion of boiler. In your case of a stationary boiler, both the above remedies should be tried.
G. BOUSFIELD.

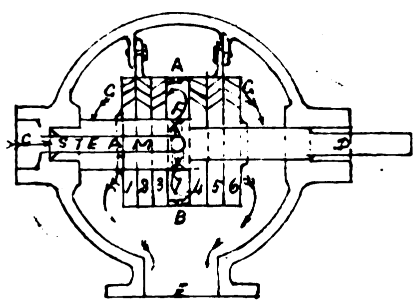
[97251.] — **Parrot Cage.** — Try as a solvent cleanser, strong alkali, or pure alcohol, and then coat over with so-called gold (or other tint) paint.
REGENT'S PARK.

[97252.]—**Telescope.**—Probably the inner curves of the flint and crown lenses are not coincident, and may be intentional. Then, when cemented, the balsam forms a third lens, which entirely alters the focal length of the pair. Remedy: remove the cement by soaking the lenses in benzoline or methylated spirit, clean carefully, and remount without cementing. Or you may have cemented the wrong surfaces together. S. BOTTONE.

[97253.]—**Crank-Shaft.** — In a general way, diameter of wrought-iron crank-shaft may be = diam. of cylinder multiplied by ·4. The diam. of steel crank-shaft may be = diam. of cylinder multiplied by 3·2; diam. of crank-pin = diam. of cylinder multiplied by ·20 to ·24. It is frequently = diam. of neck of crank-shaft multiplied by ·66. Diam. of piston-rod = diam. of cylinder in inches × ·02 × square root of initial pressure of steam. For one of steel use a multiplier of ·016 instead of ·02. Diam. of valve-spindle when of wrought-iron = diam. of cylinder in inches × ·0113 × square root of initial pressure of steam. For one of steel use ·009 as multiplier instead of ·0113.
REGENT'S PARK.

[97254.]—**Covering for Band-Saw Pulleys.**—I have put leather on pulleys thus:—A piece of good leather is cut the width and the length to just meet barely round pulley; then, having marked off the places where the fastenings are to be, I take a small centre-bit or twist-bit the size of the copper rivet-head, and make hole about $\frac{1}{16}$in. deep; then make the hole where point of centre-bit goes through the size of rivet. Drill the holes through rim of pulley the size of your rivets. The heads of rivets are on the hair side of leather, and the burrs of the rivets are, of course, underneath the rim of pulley. For years I have used pulleys treated so, and never had to repair them, or any trouble; in fact, I used to have slacker belts, which means less friction and some saving of power. MILLER.

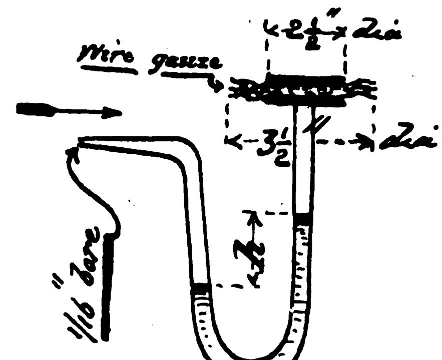
[97255.]—**Steam Turbine.**—There is nothing new about the steam turbine, or the principle on which it is constructed. I send you a sketch of one



upon the same principle as the Parson's, so much talked about. It appeared in *Engineering* about the "mid-sixties," and was said, I think, to have been driving a large engineering plant for about a twelvemonth, and giving out, I think, 100H.P. It was a spherical casing broken across the horizontal line in the centre—i.e., in two halves. It consisted of six discs, 1, 2, 3, 4, 5, 6, arranged as shown; 3 and 5 are fixed to lugs in the casing by their ears, as shown. Those are deflectors. The steam is taken one end of the spindle, C passes up steam, and makes its entry at chamber F, through the holes in spindle, passes right and left, and makes its exit at G G into casing, and exhausts at E. The driving end is D. JACK OF ALL TRADES.

[97256.] — **Windmills.** — "The Windmill as a Prime Mover," by A. R. Wolff, 2nd edition, 1894. Jno. Wiley and Sons, New York. Probably B. T. Batsford, High Holborn, could get it for you. He may have something on making wind pressure and velocity instruments. REGENT'S PARK.

[97256.] — **Windmills.** — An instrument is described on p. 376, Vol. LXV. *Engineering* which registers pressures of wind against buildings accurately. To measure velocity I suggest the apparatus shown in sketch. A glass "U" tube



with a little water in it has one end bent, as shown, and drawn out to a fine opening, the other being fitted with a sandwich, composed of two thin discs of metal with several layers of wire gauze between. The tube is in connection with the space containing the wire gauze. If the pointed end of tube is turned to face the wind, which is supposed to travel with the arrow, the water will show a difference of level = h. Then the velocity of the air in feet per second

$$= \sqrt{4370 \times h}$$
$$= 66\cdot1 \sqrt{h}.$$

"The Windmill as a Prime Mover," by Alfred R. Wolff (published by John Wiley and Sons), gives a lot of information about American wind-wheels. My copy is dated 1885; probably a later edition has been issued since. GLATTON.

[97258.]—**Annealing.**—Instead of annealing, you are case-hardening by the Harvey process—just like armour-plates are hardened in fact. Substitute fine ashes or mill scale for the charcoal, and you should have no further trouble. CLYTIE.

[97260.]—**Electric-Sparking Plug.**—Get some good pipeclay, work it up into a rather thin cream with water. When quite ready to use it, add about its own bulk of plaster of Paris, mix quickly, and apply to the portions to be cemented. Let it set quite hard before using. S. BOTTONE.

[97263.]—**Organ.**—The stops you have will make a very nice little two-manual organ; but I should advise a different distribution to that given by you, and also the continuation of the Gamba to Tenor C, with another bass. As you have mentioned my name in the matter, I shall be pleased to help you, and send specification which would be satisfactory, if you will advertise your address in the Address Column of "Ours." J. MATTHEWS.
(The writer of the articles.)

[97264.]—**Glass Harmonicon.**—I have made many of these, and can therefore advise to some purpose. The greatest useful compass is about two octaves, from C in the treble to C″. If you can get glass of absolutely the same thickness and texture throughout, then the lengths required (the width remaining the same) will be as follows:—

4 . $\frac{32}{9}$. $\frac{16}{5}$. 3 . $\frac{8}{3}$. $\frac{12}{5}$. $\frac{15}{8}$. 2 .
Do re mi fa sol la si do′
$\frac{16}{9}$. $\frac{8}{5}$. $\frac{3}{2}$. $\frac{4}{3}$. $\frac{6}{5}$. $\frac{8}{9}$. 1
re mi fa sol la si do″

Where do, re, &c., do not stand for any particular pitch, but only for the relative sequence of the notes in the octave, the numbers indicating the relative lengths of the glass strips required. A convenient width for the glass strips is $\frac{3}{4}$in. The glass should be thin and equal. As this is almost impossible to secure, a little "tuning" is often necessary, the thicker strips being made longer than indicated by the above rule, and the thinner ones somewhat shorter. To get good effects, the glass strips must not be fixed rigidly on their tapes. S. BOTTONE.

[97266.]—**Optical Lantern.**—If "C. W. C." refers to the "E. M." of March 24, 1899, p. 135, he will there find a full description, with diagrams, how to make a cheap enlarging box, which is nothing other than an optical lantern only made in wood, the light used being an incandescent burner of gas. I sent this description, and you will find it answer the double purpose of an enlarger of photographs as also a projector upon a screen. You can produce any size if you have only distance at your command. You require contact prints "positives" for projection. You cannot do without a condenser. You can obtain a 4in. one for about 6s. at an optician's. Your rectilinear will answer admirably; only do not stop it down too much. PHOTO.

[97266.]—**Optical Lantern.**—If "C. W. C." can procure or see Vols. LIII. to LVII. he will find a series of articles, which practically exhaust the construction of the optical lantern. If he procures No. 1378, August 21, 1891, No. 1381, Sept. 11, 1891, and No. 1383, Sept. 25, 1891, he will get an idea of the character of the articles, and probably all the information he wants.
SCORPIO.

[97268.]—**Hektographic Ink.**—If you make up an ink in the usual manner with glycerine, &c., and use as colouring matter only just sufficient fuchsine (hydrochlorate of rosaniline) to give a pale pink impression, you will find this easy enough to remove by the application of liquor ammoniæ and subsequent washing. S. BOTTONE.

[97268.]—**Hektograph Ink.** — If "Jersey" cares to communicate with me, I can put him in the way of doing what he wishes to do. See Address column. R. C. GILSON.

[97269.]—**Cloudy Lenses.**—J. J. Clarke is only one of thousands who have the same trouble with German work. The lens that generally goes on all Continental objectives is a single lens placed between the back and middle correcting lenses. It is constructed of one of the most perishable glasses made, though we have now scores with the front lens also "cloudy." We have had as many as thirty returned to us to be "fixed" in one week from large medical colleges. Apo. and achromatics, all with the disease. They last longer in different localities, according to climatic conditions. We had so many to do, and were tired of having them year after year, that we made a special rouge to polish them, which considerably lengthened their lives. We are afraid J. J. Clarke must send them to their respective makers, or to an optician who will undertake to put a suitable lens of a less perishable nature, which will only reduce the illuminating power somewhat. A well-known German maker was asked why he used such perishable glass, and couldn't he use glass that would last? He said: You buy a pair of shoes and do not expect them to last for ever. Why should my lenses do so?
Bognor. ENGLISH OBJECTIVE CO.

[97270.]—**American Organ.**—The best work I know of answering to the requirements of the querist is Spanswick's "Directions for Tuning and Regulating Mason and Hamlin's Cabinet Organs," published by Metzler and Co., Ltd., Great Marlborough-street, W., price 2s. It contains illustrations showing the mechanism and a description of the stops. "M." can also find a great deal about the American organ in back volumes. ORGANON.

[97271.]—**Dion Motor.**—Shut petrol taps completely off going down hill, also switch—to save petrol and battery. Note one thing, that is not generally mentioned in instructions; if hill is long the rapid rush through air, if going down with compression closed, sometimes causes specks of moisture to form, causing engine to miss first few shots, though only momentarily; therefore, if run-

ning down hill with compression closed—which is advisable for safety if the hill is steep—when nearing bottom open same, and leave it open till engine has fired three or four shots. "Never rush a hill till you can see the bottom" is a good maxim to bear in mind. The vapour-valve is merely an easy fitting round cylinder, and sometimes leaks slightly even when completely closed. A pint of petrol for 1¾ motor should carry you nine miles—less probably if the weather is damp. I could give you a sketch of carburator; but as you have one you can easily examine your own. Get a book of instructions from the British Motor Co., from whom (if you ride a Dion motor) you will receive every courtesy on application. Monty.

[97275.]—**Smoky Chimney.**—A supply of air brought from outside to the firegrate would have the same effect as the open door.
161, Albion-road, N. A. Clarke.

[97275.]—**Smoky Chimney.**—From what you state in regard to your old chimney, I suspect the grate stands too far out. In order to test this, let a small stone or plumb-line fall from inside of lintel, immediately over the fireplace. If the plumb-line falls inside of grate, the grate must be set back.
Rothesay. J. Kay.

[97276.]—**Boiler.**—Yes, ½in. is quite thick enough, providing the aluminium is alloyed with about 4 per cent. of copper. G. Bousfield.

[97277.]—**Condenser.**—Condensers, as a rule, are made with water circulating inside tubes—not outside. In your case you will require a chamber for the condensed steam to accumulate in (if there is not sufficient space left over ends of tubes), and the water is drawn from here by the air-pump.
G. Bousfield.

[97278.]—**Force Pump.**—The water must be pumped into boiler below the water-line.
G. Bousfield.

USEFUL AND SCIENTIFIC NOTES.

A daily Pullman express service between Berlin, Buda-Pesth, and Constantinople, will be established next summer, leaving Berlin at seven a.m., and arriving at Constantinople at ten minutes to ten a.m. on the third day.

According to the last annual report of the Japanese Railway Bureau, 472 miles of new line were opened during the year ended March 31st last. The total length of lines in operation was 3,421 miles. The number of railway companies incorporated under former charters was fifty-eight, with a total capital of 238,775,000 yen, with 2,652 miles of road in operation.

A project is said to be on foot which involves the raising of Loch Doon by 20ft., and converting the waters of Nees Glen into a source of energy for the driving of dynamos and the operating of electricity. The scheme consists in the construction of a light railway, which is to run into the heart of the mineral districts of Scotland. The scheme has been brought about chiefly by the finding of ironstone, lead, &c., round about the upper end of Loch Doon and elsewhere in the district.

Power of Dry Battery.—One way of defining a watt-hour is to say that the energy represented by it is equal to that expended in raising a pound to a height of 2,654ft., or two watt-hours correspond almost exactly to raising a pound to a height of one mile. Applying this to primary batteries gives results which at first sight are rather surprising, as they show how much energy is stored in them. A certain dry battery, for instance, weighing 6·38lb., yielded 130 watt-hours, which, if applied to raising the battery itself, would lift it to a height of over ten miles. In one hour the energy translated in an ordinary 16-candle power incandescent lamp weighing about an ounce would raise that lamp to a height of 400 miles at a velocity of nearly seven miles per minute.

Obesity Remedies.—Mme. Ameliere, who has tried many obesity cures without result, has succeeded in reducing her too solid flesh in a very simple way. Her usual diet is not modified; but everything taken into the mouth is masticated till it slides down the throat without the voluntary action of the person eating. Nothing is forcibly swallowed. This may seem impossible at the first thought, but a single trial will convince anyone of its practicability. Not only solid food is chewed in this way, but liquids of all kinds, tea, coffee, milk, beer, and so on. From the standpoint of economy this new method of eating is very satisfactory, because in following it one cannot take more than half the amount of food consumed in the ordinary way. When the food is thoroughly masticated, hunger is soon satisfied; and physicians have said for a long time that people eat very much more food than is necessary to keep them in health and strength. In the instance cited, at the end of twelve weeks the patient had reduced her weight 50lb.—*American Paper.*

UNANSWERED QUERIES.

The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered, are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.

Since our last, "Clytie" has replied to 96818; "M.I.C.E." 96967.

QUERIES.

[97281.]—**Straight or Curly.**—Can any reader who has had his hair cut perfectly close to head or shaved, from other reasons than illness (fever, &c.), tell me from personal experience how the second crop has come out, as in cases of fever the hair previously straight always comes out curly? I have observed it in six cases to my personal knowledge.—Rose Thorn.

[97282.]—**Automatic Feed.**—Can any reader say if it is possible to make a pump or other arrangement feed a boiler automatically? and, if filling too quickly, to stop and start again? It would be needed for a still, and must not be got too full, or it would spoil the water.—J. A. C.

[97283.]—**Motor Tricycle.**—I am building a motor-cycle, and on purpose to shorten the process, I propose to bore crank-discs parallel and keyway them, and to turn shafts to suit, but a shade larger, and keyway also, and to shin the discs on to shafts, and to key up. Will "The Writer of the Articles" or "Monty" kindly say if there is any reason why this course should not be adopted? I may say I intend to finish the turning required after the discs are shrunk on. Advice will be greatly esteemed by—Electric Spark.

[97284.]—**Geometrical Progression.**—Will "M.I.C.E.," or others, look over this? The sum of six numbers in geometrical progression is 315, and the sum of the two extremes is 165. I find that this reduces to $\frac{315 - x}{150 + x} = r$ when x = first term and r = ratio. This divided gives $r = 2$ and remainder $15 - 8x$, or $15 - 3x = 0$, or $x = 5$, so that we at once get both the first term and the ratio. For information, I would be pleased if "M.I.C.E.," or other readers, would pronounce on this method, and if wrong, why? And also give another solution in quadratics. I have no use for the solutions, hitherto, of Mr. Burgess; in a former "G.P." he found out by guessing that, as it happened, the first term and the ratio were alike, so he proceeds: "Let x = the first term," "also let x = the ratio," then he gets along swimmingly; but it is rather too thin.—Ontario.

[97285.]—**Factory Clubs.**—I should be glad if any of our readers could afford me information regarding the formation and working of clubs and institutes in connection with factories. We are offered several rooms in a building in course of erection by our firm, which we propose to turn into a social club, with reading and recreation rooms, and to set aside one big room for "smokers," lectures, &c. We are wishful to arrange for the sale of tea and coffee, &c., as well as to provide for the sale of a limited quantity of beer to the members. Any hints or copies of rules would oblige.—M. I.

[97286.]—**Specula.**—I have tried ineffectually to grind by hand an 8in. speculum, but fear the curve must be radically incorrect, as it does not polish properly, and the cause of this irregularity seems to be the difficulty in giving a regular stroke when grinding by hand. I should like to try and work another with a machine, if such a thing could be done inexpensively, and would be glad of design for a simple and easily-constructed one. The recently-reproduced photo. of Mr. Glass's machine is too indistinct to make out the several parts, and I do not see any arrangement for the side movement mentioned. Could this be effected by setting the tool eccentrically on the spindle? I have tried to test the general figure by the shadow test, but the screen appears to hide mirror altogether when brought across the cone of rays near the eye. With the pinhole and eyepiece it shows a magnified image with low-power eyepiece, but with small pinhole the in-and-out of focus images are too small, faint, and indistinct to make anything of. How is this? This test seems very difficult to master. Is there not a simpler but effectual one.—Astor.

[97287.]—**Photography.**—I have copied some photos. stamp size, to go on Christmas cards, and wish to paste them in sheets, cutting out when dry, so that by laying on a damp pad they will adhere to the mounts with a little pressure. What paste or other adhesive can you recommend?—T. Richards.

[97288.]—**Optics.**—Is it proper to call a periscopic rectilinear lens a rapid rectilinear, seeing that they have to be stopped down to $f/12$ and $f/16$ before you get reasonable definition, which is slower than most single lenses? I have a weak biconcave monocle which changes my 8in. R.R. to about 12in. focus, but the definition suffers, though the supplementary lens is placed close behind the iris with its plane true in position. Is this the usual experience? If not, can I obtain a couple of well-made lenses to alter to 7in. and 12in. focus (the former, of course, a convex). I have a biunial with 8in. portrait lenses. Can I obtain lenses that will slip into the tubes that will alter to 6in. (the aperture, of course, being proportionately reduced) without impairing the definition?—T. Richards.

[97289.]—**Double Vision.**—I should be glad if my case might catch the eye of some one of your readers who could help me. I am 70 years of age, and have had good sight until about six months ago, when very suddenly I begun to see objects double or treble. At a distance of 3ft. or 4ft. I scarcely perceive it, but at three or four yards white or bright objects like a gas jet or the white letters on a shop window or sign appear double, about 1in. apart, and across the sheet the divergence is several inches, and is very confusing. My regular doctor says it is old age; but I have not begun to feel old yet, and have excellent health. A specialist, after a month's treatment, gives it up. As I am inclined to think that the failing may have been brought by overstraining my eyes, I have wondered if closing them entirely for a week or a fortnight might be tried without risk. Any suggestion from your numerous readers would be gladly received.—F. B.

[97290.]—**Galvanometer.**—Will some reader kindly inform me if I can alter a galvanometer used by the post-office to show the number of volts in an accumulator up to five volts, say? The galvanometer has a dead-beat needle and an arc graduated 70 on either side. It has three terminals—one "intensity" and one "quantity"; also a small switch marked "full on" and "shunt." It seems a well-made instrument, which I have used for testing bell-wires, &c.—Hyde Park.

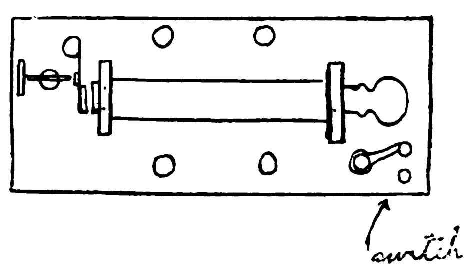
[97291.]—**Handicrafts for Working Lads.**—Some two years ago, as near as I can recollect, some gentleman gave an account in your columns of the success they had had in teaching some village lads the use of simple tools in the making of toys, &c., which were turned to profitable account. I am anxious to introduce such an idea to the manager of a working lads' club, and shall be very glad of information through your columns or to me direct.—Robert J. Parkes, Southport.

[97292.]—**Cycle Plating.**—I wish to construct an apparatus for coppering and plating cycle parts, &c. Will some reader give me a description of the most suitable and simplest kind of apparatus for cycle work? What voltage will be required from either dynamo or batteries, and which are the cheapest chemicals to use? A sketch will be most thankfully accepted by myself and many more.—G. B.

[97293.]—**Navigation.**—What moderate priced books on Practical Navigation can you recommend—i.e., with examples worked out?—T. Richards.

[97294.]—**Acetylene Gas.**—Would anyone oblige by assisting me out of a fix? I have been trying to adopt this gas for lantern work, and cannot get half enough of light. I have used 1, 2, 3 burners respectively in all positions, with a 4in. plated reflector. When you look in at the condenser the reflection has not the same brilliancy as the light has of itself, so I have got it into my head that the light is diminished. I have tried all distances from the screen. Hoping to get some encouragement—Rabbie Burns.

[97295.]—**Coil Connection.**—Would Mr. Bottone oblige by giving connections of coil, per sketch, to



terminals and switch, primary and secondary windings. Also what proportion of chemicals to charge battery with for same? Four layers of 20c.c. primary, 4oz. of 36 s c. secondary, are the amounts of wire on coil.—G. Dobbs.

[97296.]—**Gas-Engine.**—I am about to make a gas-engine, 3in. bore by 5in. stroke. I should be much obliged if any of our readers could inform as to size of compression space, valves, &c. I intend to use a liner of wrought-iron piping for cylinder, with cast-iron casing to form water-jacket. Are single-slotted crank-shafts in the rough suitable for above size obtainable? Is gas-bag necessary?—Gaseous.

[97297.]—**Lunar Volcanoes.**—Can "F.R.A.S.," or any other astronomer, give any explanation of the following, which I find in "Keith on the Globes," p. 152? Dr. Herschel on April 19, 1787, discovered three volcanoes in dark part of moon. First was nearly extinct, the third in actual eruption; the next night it burned with greater violence, and was computed to be three miles in diameter. The eruption resembled burning charcoal covered with a thin coating of white ashes. All adjacent parts of the mountain were faintly illuminated by the eruption. Is it not generally conceded that with the exception of the doubtful cases of Hyginus and Linné no well-authenticated movement has been observed on the moon? Most text-books seem to say so; but what about this observation?—Delphinus.

[97298.]—**Cements.**—I should be glad to know of cements suitable for the following purposes:—(1) For cementing silver or plate to glass—e.g., the plated rim of a glass biscuit barrel. (2) For cementing glass to brass or iron. The latter should be strong, as it is required for cementing the glass body of a large lamp to the stand.

Would dried and fused alum do for this purpose? I was at first advised to use plaster-of-paris, but have not found it satisfactory.—P. V.

[97299.]—**Budding Roses.**—What are "Manetti" stocks, on which roses are budded? Though referred to in almost every gardening book and price list that I have, the meaning is nowhere explained.—ROSA CANINA.

[97300.]—**Gas v. Petroleum.**—Will Mr. Fletcher or anyone familiar with the subject please state what quantity of good petroleum (such, for instance, as "Royal Daylight"—is equal in calorific effect to a cubic foot of ordinary (not "Cannel") gas?—the petroleum to be burnt in a central draught or other good stove, and the gas in an atmospheric burner or flat flame stove.—A. S. L.

[97301.]—**To Lanternists.**—I have a pair of oil-lanterns; but wish to change the light, as it is not powerful enough for large halls, &c. Before doing so, would like the opinion of readers. I thought of having the Rilford automatic oxygen generator, and should like to use a saturater with it; but, in looking over this month's *Lantern Journal*, I saw an explosion caused through using one. Now, I do not want my head found in a different place than my body, so if you could tell me of a really safe one I shall be very grateful, as some places that I may have to go to have not the gas laid on. Is there a good, inexpensive book on limelight?—LANTERNIST.

[97302.]—**Refracting Telescope.**—Would some reader kindly advise me what glasses to get for making a 3in. refracting telescope? I cannot afford to buy one, but I have a lathe and a fair knowledge of metalwork, and would very much like to follow the papers now appearing in the "E.M." by Norman Lattey. Probably a few hints would be acceptable to others like myself.—R. H.

[97303.]—**How to Solder.**—Will someone be kind enough to tell me the proper way to solder with the soldering-iron, stating all things needed for soldering tin, copper, and brass? Also how to make the solder?—R. H.

[97304.]—**Oxygen.**—Will some friend tell me if it is possible to make oxygen the same way as they do the new gas with carbide? If so, please say the quantity of material? Also, is there much danger in mixing it, and does it require much power to use it? Any hints on oxygen will greatly oblige.—F. ASQU.

[97305.]—**Small Milk Separator.**—Will one of "ours" kindly give particulars of how to make a small milk separator. I do not require it for dairy work, but for experimental purposes—therefore, one to hold from two to four pints of milk. Can the head, or vessel containing the milk, be made of stout tin-plate? Also, would the vertical spindle, if driven at 2,000 revolutions per minute, be too fast to be driven with light bevel wheels, the speed to be obtained from a counter spindle? Dimensions of vessel and height of spouts will greatly oblige.—MILKO.

[97306.]—**Thorite as an Explosive.**—Can anyone give me some information about the following? "Thorite is the name of a new high explosive adapted for the bursting charge of shells fired from ordinary guns. In a recent test it is said that a 7in. 182lb. shell was loaded with 4lb. of thorite, and then exploded by electricity in a 10ft. square steel inclosure. It was estimated that the fragments numbered 20,000. Thorite-charged 10in. shells have been fired through a 4½in. Harveyised steel plate without exploding." Where and when have experiments been made with thorite in 10in. shells?—F. E.

[97307.]—**Fireclay.**—What is the best method of blocking up some of the space in a common kitchener? At present the fire-space is simply a cube, more or less, a great portion of which might be blocked up to economise coals. There must be a front space and a side space next to the oven, and a top surface over the whole area; but certainly one-half of the space might be occupied with fireclay or firebrick with economy and advantage. How do you mix the clay?—KITCHEN.

[97308.]—**Soda and Uric Acid.**—I have suffered severely for years with headaches, and at times rheumatism, both caused, I believe, by excess of uric acid in the system, and I should be glad to learn from some of your capable readers if the consumption of food containing preparations of soda, such as baking-powder, &c., is likely to be injurious in my case. I think I have read that this is so, owing to the tendency of the soda to form an insoluble compound—i.e., urate of soda—which accumulates in the tissues, and causes many diseases, sometimes classed as "uric acid diseases," such as rheumatism, gout, Bright's disease, &c. In another medical work by an eminent authority, I find it asserted that bicarbonate of soda is a solvent of uric acid, and increases its excretion, thus aiding the cure of these diseases. I shall be grateful for any light upon these conflicting statements.—D. W. A.

[97309.]—**Fuller Porous Cells.**—Mr. Allop, in his book on "Electric Bells," p. 96, says: "The porous pots should be paraffined all over except a band of about 2in. at the bottom." Mr. Perren Maycock, on p. 182, Vol. XLVII. "E.M.," says: "I have had a good deal to do with this type of cell, and the base of the zinc is the more acted on because the bottom of the porous pot rests on the bichromate crystals; therefore paraffin the bottom well." And, on page 173 of the same volume, he adds: "The zincs may be short, but of large diameter, and suspended in the porous pot; the zinc is less acted on then, for when the bichromate diffuses into the porous pot it does so more at the bottom than the top, obviously." Suspending it in the pot raises another difficulty, for Mr. Sprague in his "Electricity," p. 394, says: "It will be dissolved mostly at the top, perforated with bobs or even cut through at the surface of the liquid." Here is a peculiar position of things. One authority says paraffin the bottom of the cell, the other says do not do it, and suspend your zincs; then another, equally clever, says if you suspend your zincs they will be eaten away for a certainty. Who is correct?—as so far I have had little or no success with Fuller cells.—SUBSCRIBER SINCE 1866.

[97310.]—**Armature.**—Will some reader of the "E.M." kindly inform me if the armature of an electromotor can be made to revolve in an opposite direction by means of a switch without having to change the position of the brushes? I want to change the direction of revolution at a distance from the motor. A sketch will be very thankfully received.—J. H. C.

[97311.]—**Soluble Sodium Silicate.**—Will some reader please say a word or two about soluble sodium silicate solution? What are it uses, nature, &c.?—MUM.

[97312.]—**Stereoscopic Transparencies.**—Will any reader kindly give me a little information on the production of glass stereo-photos? Are they similar to lantern slides? Is their production attended with any special difficulties for an amateur? What is the backing of opal glass intended for?—J. C.

[97313.]—**Screw Propellers.**—Would someone kindly tell me which will travel the faster of two model steamers—the one having a single screw propeller with 1in. blades, and the other having twin screws with ¾in. blades, in each case revolving at the same speed?—J. H. L. L.

[97314.]—**Wimshurst Machine.**—Will Mr. Bottone please help in the following matter? I want to make a Wimshurst machine for X-ray work, to be equal in effect to a 6in. spark coil? I have your book "Electrical Instrument Making." If I made the machine as there described, would it be efficient for the work? If not, please say where alterations are to be made, or give detailed instructions for making one. Would ebonite be better than glass for the discs?—WOULD-BE ELECTRICIAN.

[97315.]—**Increasing the Power of a Steam-Engine.**—Do any of your readers know anything about this, which I found in an American paper? "Prof. ——, of Berlin University, has invented a method of increasing the power of steam-engines, which promises to revolutionise steam-engineering. He conducts steam generated in an ordinary boiler into a cooling-tank, and then treats it with sulphuric acid, increasing its power from one-third to one-half. A factory at Charlottenburg has been using the invention for three months, and has obtained 56 per cent. above the indicated horse-power of its engines." How does sulphuric acid increase the power, and what is its effect on the metal?—D. T.

[97316.]—**Zinc Printing Blocks.**—What is the simplest process for making zinc cuts (no shading required), such as are used in catalogues, circulars, &c.?—H. WILSON, Toronto, Canada.

[97317.]—**Coaling Locomotives.**—Can any reader tell me which railway is adopting this "method" of coaling the loco.? It reads like an American yarn, but it is published in this country: "A new way to coal locomotives is being introduced by a prominent railway. All the engineer has to do is to run his engine on a trestle, touch a button, and a tenderful of coal drops into his tender, which is weighed as it drops in." Should like to know how it is done.—MIDLAND.

USEFUL AND SCIENTIFIC NOTES.

A RUN of five miles in three minutes, or at the rate of 100 miles per hour, is said to have been recorded lately on the Lake Shore and Michigan Southern Railway. Engine No. 601 hauled eight passenger and baggage cars; the train left Buffalo 59 minutes late, and ran into Cleveland two minutes ahead of time, thus making up 61 minutes lost time in 185 miles. Only three station stops were made, and the engine slowed down seven times for crossings.

THE pneumatic postal-tube service in New York includes one conduit connecting the General Post Office with Brooklyn, and the others lead to the Produce Exchange; to Madison-square; to Station D, at Bowery and Sixth-street; and to Station H, at Lexington-avenue and Forty-fourth-street. The latter line is employed for all mails going out from the Grand Central Station, and is the most used. It is estimated that 800,000 letters are sent daily through this conduit. They pass over a distance of 3½ miles in seven minutes, using about 2,000 "carriers" per day. These carriers are steel tubes, 28in. long by 6in. diameter, and hold about 300 letters each, or any package less than 6in. diameter.

AN unusually large fill has been made on the Burlington. On the Deadwood, S.D., branch is a gulch 700ft. wide, known as Sheeps Canyon. This was crossed, until recently, by a wooden bridge, 126ft. high, which took over 240,000ft. of lumber in the building. Recently this trestle was filled in. It took twenty weeks to accomplish the task. It was necessary to haul 2,880,000c.ft. of earth one and a half mile up a 2 per cent. grade, and unload off the high bridge. This required 1,486 trains of fifteen cars each—22,000 car-loads in all. The costly maintenance of the high trestle is saved and the serious danger of its destruction by fire avoided, thus warranting the expensive work.

Preserving Brasswork from Corrosion.—The use of the old lacquers where moisture or chemical fumes are absent is very effective in preserving the appearance of polished brasswork; but in the case of delicate articles used in a laboratory, such as brass weights, scale-beams, and so forth, it has been the custom to gild the surface in lieu of lacquering. Recently, however, Mr. W. A. Allen, of the State School of Mines, Rolla, Missouri, has made public a case in which a set of such gilt weights put away in a box, but evidently in a damp condition, in a safe for less than three months, were corroded and covered with a white incrustation, and he raises the question whether gold-plated weights are, under ordinary working conditions, preferable to brass.—*British Journal of Photography.*

ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries, put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

*** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

CHRISTMAS WEEK.

The CHRISTMAS HOLIDAYS will practically necessitate our going to press with the number for Dec. 29 on SATURDAY, DEC. 23. The office will, of course, be open on Wednesday, Dec. 27, and advertisements and late communications will be taken up to the usual time of going to press on that day; but advertisers and others who want to make sure of their communications appearing in the issue of Dec. 29 had better see that they reach us on SATURDAY, DEC. 23.

The following are the initials, &c., of letters to hand up to Wednesday evening, Dec. 20, and unacknowledged elsewhere:—

STUBBS.—A Fellow of the Royal Astronomical Society.—Planter.—E. J. C.—L. L.—R. M.—T. Dyson.—Clara.—J. A. C.—Novice.—Perplexed.—At Last.—T. P.—P.—A. Fillmore.—Nest-Egg.—B. J.—R. Dixon.—W. L. D.—Balbus.—T. Jordan.—X.—Waiting.

NO SIBRAH.—The Morse system is the dot and dash, in which the signals vary in duration instead of in direction. Any of the small handbooks on the telegraph give the alphabet and the various methods of signalling with the sounder or the needle. Flag and flash signalling are generally the same as the needle. For full particulars see Culley's "Handbook of Practical Telegraphy," published by Longmans.

TANNER.—Young's "Navigation and Nautical Astronomy," published by Crosby Lockwood and Son, Stationers' Hall-court, E.C., will probably suit; or Raper's "Practice of Navigation and Nautical Astronomy," published by Potter, 16s. Apply to Norie and Wilson, Tower Hill, London, for a catalogue. See the Directory of the Science and Art Classes.

H. WILSON (Toronto).—The lines are photographed or transferred on to the zinc, and the other parts are eaten away by acid. There are several works on the subject. Procure a catalogue from Dawbarn and Ward, Farringdon-avenue, London, E.C.

W. D.—1. We must refer you to back vols. for information about the Star of Bethlehem. We have no space for more. 2. Cocoa nibs should be ground in an ordinary coffee-mill, and boiled.

R. JACKSON.—We send the set of Best Books free to any part of London for 30s. by our own carts, within a few hours of receipt of cheque or P.O.O. To country buyers we deliver free on rail in a substantial wooden packing-case strong enough to stand carriage round the world.

ENGINEER.—It is, as you say, unfortunate that you cannot spare eight shillings to try the *Weekly Times and Echo* cigars when you are not sure if you will like them. We are certain, however, that you will be satisfied; but for the benefit of you and others who cannot spare so large a sum we are sending a handsome leather case containing five *Weekly Times and Echo* Cigars, post free, to everyone who sends us a postal order for two shillings.

IN TYPE.—Arcturus, Arthur M. Edwards, Hugh Alexander, Gossip.

ACCORDING to the returns recently published by Lloyd's Register, the number of steam vessels for the whole world totally lost, condemned, &c., during the half-year ended June last was 51, of a net gross tonnage respectively of 43,203 and 67,553. The United Kingdom's loss amounted to 14 vessels, of 15,679 net tons and 25,215 gross tons.

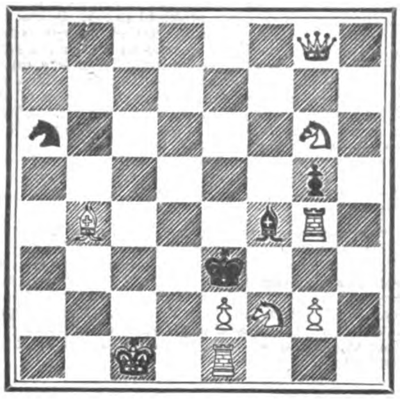
Accumulators.—A new method of accumulator construction has, it is stated, been devised in Germany. It resembles that used in the original Volta pile, the cells being piled one above the other. The battery consists of a series of shallow rectangular lead vessels with sloping sides, placed one above the other, with spherical insulators in the four corners of each vessel to prevent metallic contact. The bottom of each vessel is corrugated. From the crests of the corrugations project inwards the negative plates, while the positive plates are suspended from the lower or outer face of the corrugated bottom. When the vessels are in position the downwardly-projecting positives of any cell come between the upwardly-projecting negatives of the vessel immediately below it.

CHESS.

All communications for this column to be addressed to The CHESS EDITOR, at the Office, 332, Strand.

PROBLEM No. 1706.—By K. KRAUSE.

Black. [4 pieces.



White. [9 pieces.

White to play and mate in two moves.

(*Solutions should reach us not later than Jan. 1, 1900.*)

Solution of PROBLEM No. 1704.—By C. A. GILBERG.
Key-move, B-K B 6.

NOTICES TO CORRESPONDENTS.

PROBLEM No. 1704.—Correct solution has been received from T. Clark, N. M. Munro, Thos. Chipperfield, Rev. Dr. Quilter, A. Tupman, Richard Inwards, Whin-Hurst, J. B. Gore, F. B. (Oldham), Jas. Mason, Frank Gowing, Quizco.

ON the Boston and Albany Railroad in America 95lb. rails are used. The width of the base is 5¼in., and the height 15in. Fourteen ties to each 30ft. length are used.

IN round figures the world's production of petroleum is about 150,000,000 barrels per annum, and of that total 30,000,000 barrels are produced outside the United States and Russia. Thus Canada produced last year 758,000 barrels, but is capable of furnishing much more, as the oil area in the Dominion has been only partially exploited.

THE Soulanges Canal was recently opened, completing a 14ft. waterway between Montreal and the Great Lakes. This canal replaces the 9ft. Beauharnois Canal, on the other side of the St. Lawrence River, and connects Lake St. Francis and Lake St. Louis, between which lakes the St. Lawrence River falls 82½ft. in sixteen miles in the four rapids of Couteau, Cedars, Split Rock, and Cascades. This fall of 82½ft. is overcome by four locks—three near the Cascades, of 23½ft. each, and the fourth about three miles from the entrance. Heavy guard gates are located about 1,000ft. above Lock 4, and a guard lock, at the upper end, can be used as a lift lock when the lake rises above mean stages. This canal has cost about 5,000,000dol., and it will be operated and lighted by electricity generated by turbines developing 640H.P. for operating the generators.

SPECIAL OFFER.—CHEAP VOLUMES.

In the course of the next few months we are compelled, owing to the making of the new street from Holborn to the Strand by the London County Council, to remove our Offices and Printing Works. Due notice of our removal will be given shortly. In the mean time, to reduce stock and save trouble of removal, we offer readers desirous of making up sets of back volumes *any volume* in the list below at HALF PRICE, or post free for 4s. 1d.

Any reader desirous of making a free library or working men's club a present of a few sets of volumes will find this a favourable opportunity. The offer is only available till our removal.

TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

5s. 6d. for Six Months and 11s. for Twelve Months, post free to any part of the United Kingdom. For the United States, 13s., or 3dol. 25c. gold; to France or Belgium, 13s. or 16f. 50c.; to India, New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-Office Order. Back numbers can also be sent out by the ordinary newspaper post at the rate of 3d. each.

Vols. XXIV., XXX., XXXII., XXXVI., XXXIX., XL., XLII., XLIII., XLIV., XLV., XLVI., XLVIII., L., LI., LII., LIII., LIV., LV., LVI., LVII., LVIII., LIX., LX., LXI., LXII., LXIII., LXIV., LXV., LXVI., LXVII., and LXVIII., bound in cloth, 7s. each. Post free, 7s. 7d.

Indexes to Vol. LI., and to subsequent Vols., except Vols. LIII., LV., LVI., LVII., LIX., LXI., 3d. each, or post free 3½d. Cases for binding 1s. 6d. each.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each post free from the office (except supplement numbers, which are 3d. each, or post free 3½d.)

NOTICE TO SUBSCRIBERS.

Home Subscribers receiving their copies direct from the Office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a PINK WRAPPER, as an intimation that a fresh remittance is necessary if it is desired to continue their subscription.

Foreign Subscribers will have the Pink Wrapper sent ONE MONTH before expiration, in order to give them time to forward fresh remittance before subscription expires.

ADVERTISEMENT CHARGES.

The Charge for Advertisements in the Columns headed:—

For Exchange.
For Sale.
Wanted.
Addresses.
Situations.

is Sixpence for the first Sixteen Words, and Sixpence for every succeeding Eight or part of Eight, which must be prepaid. *No* reduction on repeated insertions. Advertisers should state under which heading they wish their announcements to appear.

The address is included as part of the Advertisement and charged for. No displayed Advertisements can appear in above columns. Rates for Displayed Advertisements are as follows:—

For advertisements on inside pages, except page facing leader, for less than a quarter-page; per inch single column—

1	6	13	26	52 insertions
7s. 0d.	6s. 6d.	6s. 0d.	5s. 6d.	5s. 0d. each.

FRIDAY, DECEMBER 29, 1899.

DARK-ROOM ILLUMINATION.

By REGINALD A. R. BENNETT, M.A.Oxon.

AT first sight, the above title may appear somewhat of a contradiction, seeing that if a room is "illuminated" it is not "dark." But to the photographic tiro to whom I am addressing myself it will be a well-understood combination. The problem of the illumination of the photographic dark-room is, indeed, one which meets the enthusiast at the outset of his career, and there is, perhaps, not one which is more fraught with the burden of his future success or failure, or on which his comfort in the manipulation of various processes more greatly depends. As an amateur myself, and dependent largely upon my own ideas for the solution of this problem in the way best suited to my circumstances, I have been through many periods of discomfort, which might have been avoided if I had had a knowledge of how to arrange matters in the best way at first. I therefore contribute this article to "Ours," in the hope of saving my readers unnecessary tribulation, the methods

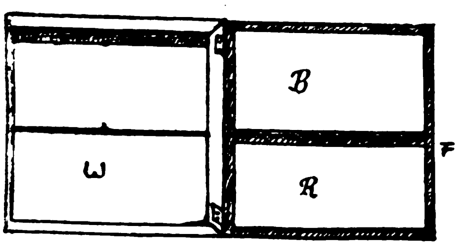

FIG. 1.—Method of Covering Window with Ruby Fabric temporarily. W, window; F, frame hinged to window frame; B, brown opaque paper; R, ruby fabric.

that I advocate being suitable to any circumstances.

Let us first consider the case of an ordinary room of which it is desired to darken the window for use in photographic work. In the first place, it is not desirable to darken the window itself; this would mean that the room had always to be lighted with a red light, which is most objectionable, as it is unnecessarily trying to the eyes. The original glass is, therefore, to be left clear, and the window should also be left free to open, the chemicals used in the work sometimes giving rise to objectionable fumes, so that free ventilation at intervals is important. The darkening arrangement has, therefore, to be independent of the window itself.

To effect this in the simplest manner, supposing the window is a small one, we can make a frame fitting tightly inside the sash, and supported on one side by hinges which allow it to be swung outwards inside the room when not wanted. Fig. 1 shows my idea of this arrangement. The top of the frame is covered with thick brown paper in which there is not a single pinhole, and the bottom with ruby fabric. This is best double, and I like to add a third covering of canary fabric, which gives a more pleasant light, and is an additional safeguard. The frame, as will be seen, has a bar across the middle between the different coverings. The wood is any suitable wood—deal will do—and the sides of the frame are about 1in. thick and 2in. broad. The outside measurements will, of course, be exactly such as to fit the sash of the window. It is best to cover round the outside of the frame with thick cloth or velvet to entirely exclude all light when the frame is pressed against the window-sash. It fastens on the opposite side to the hinges, either by a latchet or a wooden "stop" which moves down out of the way when not wanted, but presses the velvet against the woodwork

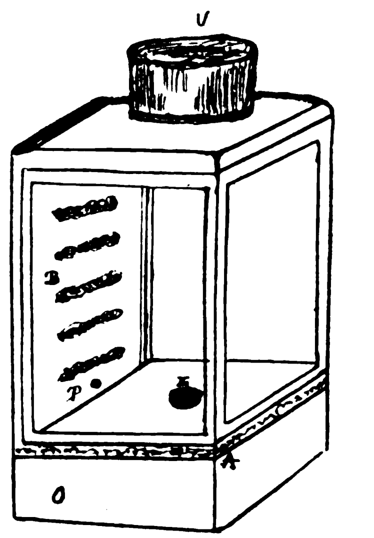

FIG. 2.—Lamp for Oil, complete. L, hole for lamp; V, top ventilator; A, ventilating chamber; B, holes for ventilation in back; O, vessel for oil.

of the window when it is placed horizontally, and at right angles to the frame.

Supposing the window is too large to be arranged in this way, or that there is an objection to the frame being moved out into the room when not wanted, it is necessary to so arrange matters that the frame can be removed entirely from the window-sash and deposited in any suitable place when not required. This I have achieved by the simple plan of constructing the frame in two portions, one of which fits on the top of the other, and when both are placed in their proper position their combined height is exactly that of the window-sash frame. Of course, the breadth of each frame is also such as to fit pretty tightly into the inside of the sash, so that when put together the whole window is covered. The top frame is covered with thick brown paper, and the bottom one

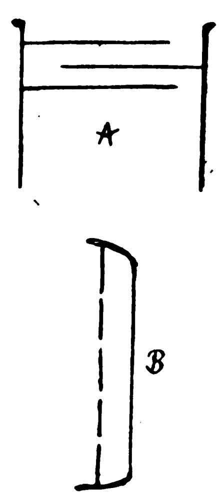

FIG. 3.—Tin Strips Forming Ventilators. A, strips inside top ventilator of lamp; B, strips on back or side of lamp, inner strip bored with holes—section as seen from top.

with the ruby and canary fabric, or if very large you can cover both with brown paper, cutting a smaller space in the bottom covering, over which the fabric can be glued. Care must be taken that no light can get in between the frames when inserted in their place in the window. To prevent this cloth or velvet should be glued between the bottom and top edges, and an overlapping piece of wood provided, which will project over the join when one is on top of the other.

For extra sensitive plates it is a good plan to have a small extra frame covered with ruby medium, which can be placed in front of the larger one, thus diminishing the light till development is far advanced, when it can be removed and the light increased for the remainder of the time.

An alternative method of darkening a small window is by means of a blind which traverses the outside of a window-sash frame, the edges being held in deep grooves down the side, so as to exclude light at the sides. The blind is made of opaque black material, and has a space cut in the bottom part which is covered with ruby and canary fabric. This rolls up with the blind when drawn up. This is about the most simple plan of all, but it necessitates a good deal of care in fixing the blind top and bottom to exclude the light at these points.

These methods will serve for those who work by daylight, but many workers cannot do this, and in their case some sort of artificial light is a necessity. In the case of the work under consideration artificial light resolves itself into one of four methods—either (1) candles, (2) oil, (3) gas, or (4) electricity. Of these, 1 is the worst, the wax being objectionable, while 4 is the

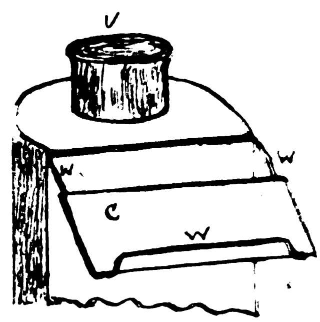

FIG. 4.—Shade for Lamp. W, W, W, wire to hold shade; C, cardboard strip forming shade; V, top ventilator of lamp.

best if there is electricity laid on in the house; but if it has to be made by the amateur it probably means too great an expense to be worth while to employ it. Gas can only be employed by the worker in towns, so that for general use the most frequently serviceable is 2—viz., oil.

As the illumination of the entire dark-room is very desirable, I prefer a lamp which has all its sides of glass rather than one which has only its front transparent. The construction of a lamp in this style is a simple matter. It can take the form shown in Fig. 2, the sides being deep ruby glass, and the corners formed of metal or wood grooved to hold the glass. The important point to be considered in this, as in all other lamps, is the ventilation. This is provided either at the back (if this is opaque) by means of holes covered with metal strips fitting across one another in such a way as to allow of the free passage of air while excluding light, or if all the sides are of glass, by a metal frame at the bottom containing similar holes. In either case a similar arrangement has to be made at the top by means of more tin strips, the simplest arrangement of which is shown in Fig. 3. As the top invariably becomes very dirty and incrusted with soot when candles or oil are used, this should be made easily removable when required for cleaning purposes. It also can have a ventilating chamber at the bottom, as shown at A in Fig. 2.

I have always found the light cast by a flame inside a lantern of which the front is plain ruby glass to be uneven, a shadow of the flame being usually visible on the surface of the plate if this is placed close to the lamp during development. As this interferes with

an accurate examination of the image as it appears, I always fasten a piece of ruby fabric before the glass in front of the lamp.

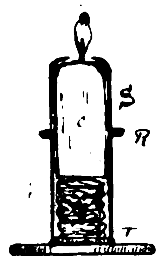

FIG. 5.—Holder for Candle of Candle Lamp. C, candle; S, socket for candle; T, spring forcing up candle inside socket; R, rim to prevent top of lamp from descending too low.

That at the sides of the lamp is not of importance. The ruby fabric gives an even illumination, and may also add to the safety of the light given by the lamp. Another addition that I have found useful is an eye-shade to protect the eyes from the light while developing. This can be simply a piece of white cardboard supported on a wire support

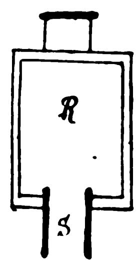

FIG. 6.—Top of Candle Lamp. R, ruby window; S, socket for candle-holder.

in front of the lamp at such an angle as to protect the eyes and yet allow the plate to be brightly lighted up. Fig. 4 shows the method of doing this.

If lighting by means of candles is the method adopted, the candle should be contained in a socket, through the top of which the candle is slowly forced by means of a spring as it burns. This avoids the production of large quantities of melted grease, which frequently takes place if the candle burns unequally,

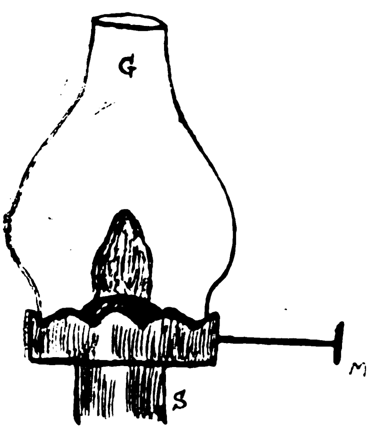

FIG. 7.—Method of Constructing Top of Oil Lamp. S, socket of wick-holder; M, milled head to turn up wick; G, glass.

and this is apt to occur if the lamp gets hot. The socket is shown in Fig. 5, where may be seen the spring S, which is kept in its place by a stand which screws to the bottom of the socket after the spring has been inserted beneath the candle. This socket and candle enter beneath the bottom of the lamp, being contained in another socket (just large enough for the tube containing the candle to fit it rather tightly) attached to the bottom of the lamp (see Fig. 6); it is prevented from descending too low by a rim round the candle-socket, which supports it at the right point (R, Fig. 5).

The oil-lamp is provided with a glass chimney in the better class of lamp.

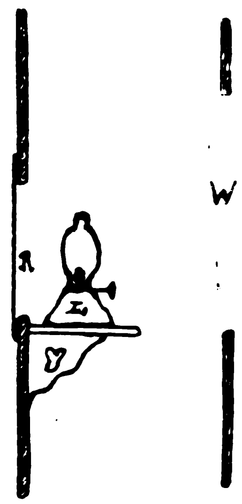

FIG. 8.—Method of Lighting Cupboard Inside a Room by Day or Night. W, window of room; R, ruby window of cupboard; L, lamp to light cupboard by night.

Whether this is so or not, I strongly advise you never to use a lamp without an arrangement for turning up or lowering the flame from the outside. This takes the form of a long axle which projects outside the lamp, and has a milled-head screw at the exterior extremity, and the usual wheel to rack the wick up and down at the other end (see M, Fig. 7). Lamps without this arrangement are exceedingly apt to get the operator into an awkward fix, for as the lamp gets hotter the flame is sure to rise, and if it cannot be turned down will smoke, or in bad cases may crack the ruby glass. As it is impossible to turn down the flame without opening the lamp, which is fatal to the negative if being developed, it is obvious that this is an unpleasant predicament in which to be placed. Of course, lamps lighted with gas should have a tap outside the lamp by which it can be turned up and down if required. Similarly, the electric lamps can be turned on and off by means of a switch, but in the case of electric lamps it is best to use a bulb of a ruby colour to contain the filament, and it is not at all necessary to inclose the lamp in a larger erection surrounded with ruby glass. This causes the electric arrangement to take up very considerably the least space of the three methods of lighting.

In the case of the lamp illustrated in Fig. 2, it is necessary if oil is employed to have some arrangement whereby air can enter freely, either at the bottom or the back. Some holes can be drilled in the back, which are covered with a plate outside which allows air to enter, but not light to escape, the system is shown in Fig. 2 at B, and in Fig. 3 at B, as seen from the top outside the lamp.

If a cupboard inside the house is used for developing, an excellent arrangement is not to have any lamp in the cupboard, but to light it by a ruby window which can be illuminated either by daylight, or by a gas jet placed just outside it, and which can be turned up or down from inside the cupboard. The plan of thus lighting the room is shown in Fig. 8. Failing gas, a lamp can be placed on a bracket just outside the window, as shown. These methods have the advantage that they entirely avoid all smell inside the cupboard from the gas or oil, which is a considerable advantage if the space in the cupboard is somewhat restricted. It is also a good thing to be relieved from the fear of an upset—a serious calamity if paraffin is used.

If electricity is used, and there is no main in the house, the most adequate method of producing the current will be by means of a small accumulator; but unfortunately they require recharging, and will not last for a long time, even if not used. There are some primary batteries of the bichromate type which may be used, but all are apt to polarise, and the light thus gradually fails. The best

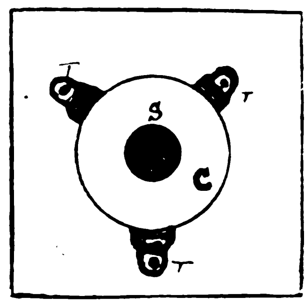

FIG. 10.—Inside of Bottom of Lamp. S, socket for candle or night-light; C, circle of tin over air-hole; T, T, T, tin supports to hold up tin circle.

I have found to be that known as the "chloride" battery, which lasts longer than the ordinary bichromate. The inner cell of this contains solution of chloride of zinc, and the outer cell saturated solution of bichromate of potash two parts, common hydrochloric acid one part. To keep the zinc in the inner cell amalgamated, a little metallic mercury (about ½oz. to 1oz.) can be placed in the inner cell. The outer cell contains the usual plate of carbon.

When travelling about one great source of difficulty is the illumination of the dark-room, which is usually a small ordinary apartment or cupboard, and unprovided with a proper window of ruby glass. In many cases it can be made temporarily suitable by placing a sheet of ruby fabric over it; but if this is impossible, one can block out the window and use a lamp. Under these circumstances a lamp is required which will fold into a small compass, and is easily carried about.

The construction of such a lamp is shown in Fig. 9, where there are seen four sides of tin, in which are cut square holes to allow

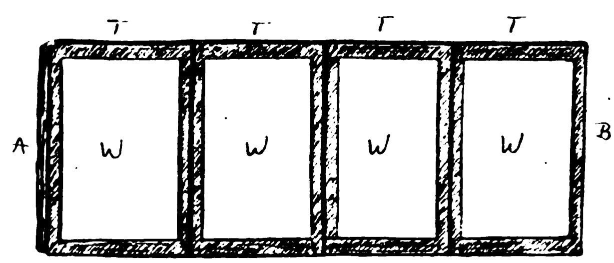

FIG. 9.—Method of Constructing Folding Lantern. T, T, T, T, tin framework; W, W, W, W, holes forming windows, covered with ruby fabric. The end B fastens to the end A, which is turned over to form a catch.

the light to pass out. I recommend that the lamp should be of a tolerable size. Those usually sold are far too small, and there are few things more disastrous than to have the lamp suddenly set on fire while you are developing, thus flooding the room with actinic light. I should construct each side of the lamp at least 5in. by 7in. The hole in the centre can then be about 4in. broad by 6in. high. The four plates are simply joined together by the ruby fabric, which is secured to them by turning over the ends of

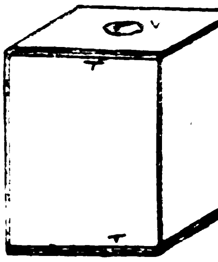

FIG. 11.—Folding Lamp complete. V, hole for air exit; T, T, top and bottom of tin.

the tin, or otherwise, and thus form a framework which will easily fold at the joins. The end pieces are arranged to lock together when the framework is set up by bending the end A of the left-hand piece in Fig. 9 into a spring, which fastens over the other end, when it is placed against a ledge forming a stop, which is soldered to the interior of the strip, and against which the edge B of the opposite end rests. When thus set up, the whole framework is inserted in a square of tin, forming the bottom, the edges being turned up to hold it. There is a similar square at the top. In both these squares are cut central holes, about ¾in. in diameter, for the purpose of ventilation, and over each hole on the inside is fastened a larger circular plate of tin, which keeps the light from issuing from the hole. The top needs no support; but the bottom should be supported upon four legs at the corners to allow the free entrance of air into the interior. The inner plate is shown in Fig. 10. In the case of the bottom, the circle supported above the hole is surmounted by a socket, in which is placed the candle which lights the lamp; the light, of course, issues from the ruby medium where it crosses the

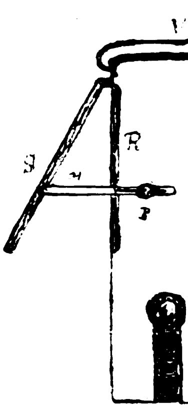

FIG. 12.—Travelling Lamp to Burn Oil.—V, ventilator; S, shade, which protects glass when folded down; H, holder for shade; R ruby glass; P, screw for fixing shade-adjuster in any desired position, which passes through slit in side of lamp; M, head of screw turning up wick from outside.

holes in the tin, which thus form windows for the lamp. The lamp outside, when complete, is shown in Fig. 11.

If an oil-lamp for carrying about is required, I prefer one which has a "vapour" lamp attached; that is, one which contains cotton-wool or wadding, which is saturated with paraffin, and not the oil itself in much quantity. Also it is most desirable that it should have a lamp which can be turned up from the outside. It is easy to construct a small lamp, the ruby-glass of which is protected by a metal shutter which forms an eye-shade when turned up to uncover the glass. Such a lamp is shown in Fig. 12.

MILLWRIGHT'S WORK.—XXII.

WE have now to consider rather briefly the transmission of power by toothed gearing, as an alternative to that by belting and ropes. That is, we cannot enter so much into questions of wheel design, but rather into the broad features of this method of driving, and into some practical hints for the millwright. One point in its favour is that it is positive. But as the slip of belting when properly fitted does not exceed about 2 per cent., this is hardly worth consideration. Objections to slip are however of weight in spinning-mills; and well-governed engines, and transmission from the prime mover by toothed-gearing is then often adopted.

Although numerous instances have occurred in which toothed wheels have been taken out of mills and rope drives substituted, yet it is necessary to remember the limitations of the latter. Very many cases occur in which shafts are so situated that there is no choice open, because toothed wheels alone will meet the conditions.

The principal advantage in toothed gearing lies in this: that power can be transmitted by it to adjacent shafts which are too close to be driven by belting or ropes, excepting by the return methods illustrated in a previous article. Also, that it can be transmitted to shafts at right angles, which can only be done with belts or ropes having twisted drives. Although the services of toothed gearing have been lessened in this field, yet there are many drives having the characteristics indicated, for which it still affords the best, and in some instances the only available, method.

It is at high speeds chiefly that the objections to toothed gearing become greatest. Wheels are noisy, and knock themselves and their bearings to pieces. But there is another side to the question. The reputation of toothed gearing has suffered largely from the sins of bad design in the past, teeth having been incorrectly designed and badly proportioned, and wheels hung on shafting with bearings of the rigid type. The mortise-wheel is invaluable in mill drives, in diminishing noise and conducing to smooth running. Even supposing, which is a wild supposition yet, that cut gears should be used in mills, they would not be so good as the wood and iron combination. There is no backlash in these when new, and the elasticity of the wooden teeth absorbs most of the vibration, so that high speeds are practicable as long as the bearings and general fittings remain in alignment, and but little worn.

When shafts run parallel with each other, too close together for a direct belt drive, then there is no alternative but to drive by gearing, or by an indirect belt drive. As a general rule, gearing is then the better mode of transmission. In such cases spur-wheels are used, made of the relative proportions to transmit the required velocity ratios.

When shafts have to run at right-angles with each other, then bevel-wheels are employed. Practically the only alternative and rival to this is the rope drive taken off to separate floors. Speaking generally, this is to be preferred, and obtains more favour in modern mills than bevel wheel main drives. But numerous subsidiary details of arrangement occur, in which the rope drive cannot well be utilised, as in transmitting power by short lengths of shafting, and here the great value of the indispensable bevel wheels is seen, by means of which any velocity ratios can be transmitted. Besides this, the bevel wheels are adaptable to driving at many angles other than the right angles, for which very awkward twisted drives with belting or ropes would otherwise be necessary. There are some types of gearing used in machinery which are rarely employed in mills—namely, the worm and screw gears, for the reason that they are too wasteful of power for heavy transmissions.

There are some important differences in the old and in modern gearing, which tells in favour of the latter, and which must be noticed. One relates to proportions of teeth, the second to other proportions.

During a period covered roughly by the last ten years, much improvement in tooth forms has been apparent. The principal difference lies in tooth lengths, which have been shortened in the best practice. Changes of this kind cause inconvenience in the mating of new wheels to old ones, and should not be adopted without substantial reasons. The fact that tooth lengths have exceeded their best limits had been suggested long ago, but little improvement has been noticeable until Mr. Michael Longridge made a special study of the subject, and demonstrated that a large number of tooth fractures in mill-wheels were clearly traceable to their long teeth. He advised, in consequence, a length of tooth equal to about one-half the pitch.

This seems very short to those accustomed to the old teeth, the length of which measured generally twelve-fifteenths of the pitch, and some certainly exceeded that length. But that the old were wrong, and that the new proportion is correct is clear from the following considerations. (Compare with Fig. 144.)

The length of a tooth is merely a matter of convenience—that is, it has no relation to the radius or leverage of the wheel. The strength of a tooth is governed by the width or thickness a, which is determined by the pitch. From one point of view, the shorter a tooth is made the better, since it would be really better to drive by frictional contact than by teeth at all. The shorter the teeth are the less is there of sliding action, and the less trouble is experienced in consequence of the extremes of thickness at point and root. These are points in favour of the short tooth, shown by full lines in Fig. 144.

On the other side, little can be said in favour of the long tooth indicated by the dotted line in Fig. 144, except its antiquity and an increased

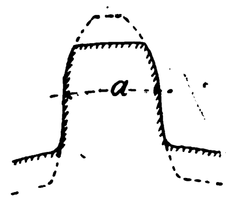

FIG. 144.

wearing surface. It is clearly a relic of the times when exact dimensions in the sizes of wheels and the centring of shafts were difficult of attainment, and when the length of tooth was made to a considerable extent the means of adjustment, being put closer into, or farther out of gear to suit the shafts, or to allow for wear. Another point was, perhaps, that a long tooth pleased the eye better than a shorter one. It looked noble, shapely, and capable of doing some work. As a cantilever, however, the longer a tooth is, the weaker it is.

With short teeth, these evils are reduced to a minimum. The limit to this shortening seems to be only that at which wheels will remain in mutual gear without possibility of jumping and overriding. This opens up the question of the degree of accuracy attainable in mill work, and that of good design. It presupposes stiff shafting, good bearings, and due provision for taking-up wear.

Better results are now observable in the general proportioning of wheels which has followed upon their moulding by machine. It is common practice now to make nearly all heavy and medium-sized wheels by machine, instead of from patterns, or by means of sweeps and core-boxes. The latter was never, except in the hands of very careful men, a satisfactory method; but it was practically the only way before the use of wheel-moulding machines became general. Firms possessed so-called "standard" patterns, which might, however, be good, bad, or indifferent, and there was a good deal of making up and stopping-off done. The consequence was that the gearing in a good many shops and mills was such that it would have puzzled a mathematician to deduce a common formula for any detail of the same. Some wheels were proportioned much too light, others much too heavy, with the inevitable results. The wheel machines, too, have rendered possible the cheap moulding of helical gears, which could not be made economically from entire patterns, and these conduce to smooth running.

Much of the trouble of toothed wheels is due to back-lash, which is the play of the wheel-teeth

in relation to each other by the amount of flank clearance allowed. With a longer tooth it is generally found desirable and safer to allow rather more clearance than with a short one, due to increased inaccuracies in the lengthened tooth profiles. On machine-moulded wheels less clearance would be allowed than on pattern wheels. On cut gears none at all is allowed. Neither is there any on mortise-wheels, which is one reason why they run so sweetly when new.

In reference to the methods of striking out wheel-teeth, the cycloidal forms still rule, and are likely to do so, because they are better adapted to a wide range of interchangeability than the involute shape. If it were not for the frequent occurrence of small pinions, then the involute basis would in some respects be preferable. In practice no trouble occurs with well-made cycloidal teeth, while it is easy on that system to get perfect gears in all wheels ranging from 11 to 12 teeth, up to 150 to a rack.

Cast iron, as heretofore, holds its own as a material for heavy gearing. For pinions subject to much stress and wear, phosphor-bronze and steel are employed in an increasing degree. Latterly the raw hide gears seem to be coming into favour. The practice of casting wheels in halves is adopted more frequently than of old, a practice which is easy on the wheel-moulding machine, though rather expensive when full patterns are in question. But the advantages are great, and there need be no sacrifice of strength. It is on a par with casting pulleys in halves. You have not to pull down a whole length of shafting to take off or put on a wheel, and there is no bother with driving the wheel endwise to get it on or off. Though wheels in halves cost a little more than solid ones, the cost is often more than saved in time in erecting, &c. J. H.

ASTRONOMICAL NOTES FOR JANUARY, 1900.

WITH the imminent advent of the last year of the present century, we commence yet another series of our Astronomical Notes, which will, however, differ in no respect from their predecessors, either in subject or arrangement. Inasmuch, though, as many of our younger readers may well commence their use of them with this monthly instalment, we shall follow our annual practice of explaining every table which may seem to require it, and supplementing such explanation, when requisite, with numerical examples fully worked out.

Turning now to Table I., that headed "The Sun." The second column gives, for every fifth day of the month, the instant which should be shown by a clock regulated to keep Mean Time, when the Sun is on the Meridian of Greenwich, and a sundial there marks 0h. 0m. 0s. What is called in the almanacs "The Equation of Time," or the amount to be added to—or subtracted from—this instant of apparent Solar Noon is calculated for the Meridian of Greenwich, but may, for practical purposes, be employed for any station in the United Kingdom, since the most westerly point in Ireland, Valentia, is only 41m. 23s. west of Greenwich (less than 0·69 hour), and the hourly variation in the equation, which is only 1·189sec. on the 1st, diminishes to 0·375sec. by the last day in January—a quantity which the most gigantic sundial ever constructed is wholly incapable of showing. Columns three and four give the Right Ascension and Declination of the Sun, to the nearest second of time and of arc respectively, at Greenwich Mean Noon on the days specified. The quantity which appears in the last column, under the heading of "Sidereal Time at Greenwich Mean Noon," is one which is very frequently required by the observer, that he may thence deduce the instant of Sidereal Time at *local* Mean Noon at his own station. This he effects by adding 9·8565 seconds for every hour (and proportional parts for minutes and seconds) when the place of observation is to the west of Greenwich, and by their subtraction when it is to the east of it. A couple of examples will make this clearer. Suppose, then, that an observer at Milford Haven wishes to find the Sidereal Time at his local Mean Noon on Jan. 1. We see below that the Sidereal Time at Greenwich Mean Noon on that day is 18h. 42m. 43·51s. Now, Milford Haven is 20 minutes west of Greenwich, so we say 60m. : 20m. : : 9·8565s. : what we shall find to be 3·2855s. If, then, according to the precept, Milford Haven being west, we add 3·29 seconds to 18h. 42m. 43·51s., we obtain 18h. 42m. 46·60s. as the Sidereal Time at Milford Haven at Local Mean Noon on New Year's Day. Or, suppose that we want to ascertain what will be the Sidereal Time at Yarmouth Mean Noon on January 26th. Turning to our table, we find that the Sidereal Time at Greenwich Mean Noon on the day specified is 20h. 21m. 17·43s. Now, Yarmouth is 6m. 52s. East of Greenwich, so we say, as before, 60m. : 6m. 52s. : : 9·8565s. : 1·12802s. If, then, from 20h. 21m. 17·43s. we subtract 1·13s., we finally get 20h. 21m. 16·30s. as the Sidereal Time at Yarmouth Mean Noon on the day in question.

As the sunspot minimum continues, the observer of the Sun's disc will find but little indeed to reward his scrutiny, long periods elapsing between faint exhibitions of Solar activity.

At 6h. a.m. on January 2nd the Sun will be in Perigee. In other words, the Earth will be in that point in her orbit at which she approaches most closely to him. At this instant an interval of only 91,338,416 miles will separate us from the mighty centre of the Solar System.

E, East Longitude; W, West Longitude; R, Sun Rising; S, Sun Setting.

The only columns in the above table that require any explanation are those headed "Moon's Terminator," which are intended to show the angular distance east or west of the Terminator (or line dividing the light and darkness) from the central Lunar Meridian at the instant of the moon's southing at Greenwich. The letters R and S in the column headed "Sun," indicate whether the sun is rising or setting on the moon at the time indicated. The use of this is to show whether the Lunar Phase is favourable for viewing any particular crater or other formation at or about the time of the moon's passage over the Meridian.

The Moon will be in Conjunction with

This table gives, to the nearest hour, the times at which the Moon will enter the various Zodiacal Constellations during her monthly journey through the sky. Among other possible uses to the student, it may help him to acquire a naked-eye acquaintance with the constellations.

In the table given below, the column headed "Moon's Limb" indicate whether it is at the bright or the dark limb of the Moon that a star disappears (or reappears). From New Moon to Full Moon disappearances occur at the dark limb, and reappearances, of course, at the bright one,

Occultations of (and near approaches to) Fixed Stars by the Moon, visible at Greenwich

† Near approaches.

and *vice versâ* from Full Moon to New. It may occasionally happen that an occultation occurs so very nearly at the actual time of the Moon being full that both disappearance and reappearance seem to take place at the opposite bright limbs of the Moon. In the columns headed "Angle from N. Point" and "Angle from Vertex," the North Point is that point in the Moon's limb cut by a great circle passing through her North Pole of the heavens and through her centre; while the vertex is that point in her limb similarly intersected by a great circle passing through the zenith and through her centre; being, in short, the top of the Moon as seen with the naked eye.

It will be seen at once that the North point of the Moon and her vertex can only coincide when she is actually on the meridian. Angles are measured from these points in the direction N., E., S., and W., or in an opposite direction to that in which the hands of a clock or watch move. As, however, an astronomical telescope, of course, inverts, the north or initial point must quite obviously be at the bottom of the field. In the case of near approaches (marked † in the column headed "Disappearance") as seen from Greenwich, we give, in terms of the points of the compass, in the column under "Moon's Limb," that part of the limb which most nearly approaches the star, because it often happens that a star which the Moon just clears as viewed from Greenwich, is actually occulted as seen from another station. Take, for example, the near approach of the 6·4 magnitude star 5 Cancri on the night of the 15th. As it is just S.S.W. of the Moon's limb as seen from Greenwich, it quite obviously must be actually occulted as observed from a station situated at any considerable distance to the N.N.E. of the National Observatory.

Mercury

is a Morning Star; but, owing to his very considerable South Declination, is badly placed for the observer. The angular diameter of his little disc shrinks from 5·8″ on January 1 to 4·8″ at the end of it.

Day of Month.	Right Ascension.		Declination South.		Souths.		
	h.	m.	°	′	h.	m.	
1	17	14·9	21	58·8	10	32·5	a.m.
6	17	43·8	23	1·6	10	41·6	,,
11	18	14·9	23	40·8	10	52·9	,,
16	18	47·3	23	51·2	11	5·6	,,
21	19	20·8	23	29·8	11	19·4	,,
26	19	55·0	22	34·1	11	33·8	,,
31	20	29·7	21	2·5	11	48·7	,,

It will be seen from the above ephemeris that Mercury, starting in Ophiuchus, will cross the whole width of Sagittarius, and be found at the end of the month in Capricornus. The majority of the stars in these constellations are small, and the planet will not approach a single conspicuous one during his journey through them. He will be in conjunction with Saturn (0° 51′ south of that planet) at 1 a.m. on the 8th.

Venus

is an Evening Star throughout the month, and as her South Declination is daily decreasing, she may be seen, especially towards the end of the month, glittering over the south-west horizon. Her disc, whose angular diameter increases from 11·4″ on Jan. 1st to 12·8″ by the 31st, is perceptibly gibbous, but she scarcely yet presents an object of much interest in the telescope.

Day of Month.	Right Ascension		Declination South.		Souths.

26	22	41·0	9	53·9	2	19·3	,,
31	23	3·7	7	25·6	2	22·3	,,

The path thus indicated begins in Sagittarius, crosses the entire width of Capricornus and Aquarius, and terminates in the confines of the last-named constellation and Pisces. The brightest star she will approach is the 3rd-magnitude one, ζ Capricorni, less than 1° to the north of which she will be found on the evening of the 13th. It is, however, doubtful if this star is of sufficient size to be visible in the twilight.

Mars

is quite invisible—a remark equally applicable to **Saturn.**

Jupiter

does not rise until just before 5h. a.m., and Uranus even later still; but

Neptune

continues in an excellent position for the observer, and is visible throughout the working hours of the ordinary amateur's night.

And on other occasions when daylight will render the phenomenon invisible.

Shooting Stars

are not very abundant in January. The principal shower during the month may be looked for on the night of the 2nd, fortunately moonless. It is that of the so-called Quadrantids, whose radiant point in the sky is situated in R.A. 15h. 20m., and in 53° Declination North—i.e., between 6° and 7° South of the 3·4 magnitude star ι Draconis. Other and less conspicuous displays from various radiants are predicted for the nights of the 3rd, 11th, 17th, 22nd, 25th, and 29th.

* Early morning of the 2nd.

We speak of the "Fixed Stars," and were it true that this was a rigorous description of them, then would each one South 3m. 55·9s. (i.e., 235·9 seconds) sooner every day, as shown by a clock regulated to keep ordinary or Mean Time. But although this is not absolutely accurately the case, it is quite sufficiently so for our present purpose, as regards by far the greater number of the stars, for us to assume that it is so; so that to find very approximately the Greenwich Mean Time of Transit of either of the stars in the above list on any other night in January, we have only to multiply 235·9 seconds by the number of days which have elapsed since January 1st (i.e., by the day of the month—1), and subtract the product from the time given in our table. For example: At what time will α Orionis cross the meridian of Greenwich on the night of January 21st? On that of the 1st we learn from our table that its transit will occur at 11h. 5m. 15·12s. G.M.T. Multiplying now 235·9 seconds by 20 we get 4,718 seconds, or 1h. 18m. 38s.; and if we subtract this from 11h. 5m. 15·12s. we get 9h. 46m. 37·12s. Actually, and as matter of fact by rigid computation, the star will South at 9h. 46m. 36·91s., or 0·21 second sooner than our rough-and-ready method of calculation would indicate that it will do. But it must be a very marvellous ordinary clock or watch that could indicate 0·2sec. The discrepancy would have been slightly more noticeable had we employed Polaris; or, in fact, any fairly close circumpolar star; but such stars cross the meridian so very slowly, and hang, so to speak, so on the transit wires, that for the purpose of rating a watch or clock, it would, as in the former case, be in practice inappreciable. We do not, however, all live on the meridian of Greenwich, and we may, and often do, require to find the local time of transit of the stars in the above list at our own station. This we obtain by subtracting 9·8296sec. for every hour of longitude (and proportional parts for minutes and seconds) when such station is West of Greenwich, and by the addition of that quantity when it is to the East of it. Thus: At what time will α Arietis South at Falmouth on the night of January 1, 1900? Falmouth is 20m. 8s. West of Greenwich, so we say 60m.: 20m. 8s. : : 9·8296s. : 3·29838s. Falmouth being west, we subtract this result from our tabular time, and say 7h. 17m. 38·37s. − 3·30s. = 7h. 17m. 35·07s. the Falmouth Mean Time of southing of α Arietis on the first night of the New Year. Or suppose we require the Norwich Mean Time at which Capella will cross that Meridian on the same night. Norwich is 5m. 12s. East of Greenwich, so, as before, we say 60m. : 5m. 12s. : : 9·8296s. : 0·8519s. As Norwich is east, we now add the quantity just obtained to the Greenwich Mean Time of transit. Thus: 10h. 24m. 55·19s. + 0·85s. = 10h. 24m. 56·04s. : and this is the local mean time at Norwich at which Capella will be due south on the night of January 1, 1900.

TEACHING THE LAWS OF BINOCULAR VISION.

THE movement and various changes that take place in the human eyes when looking from one plane to another, are exceedingly complex. Beside the actual turning of the eyes under muscular control, each separate eye undergoes that change known as accommodation, which may be taken to mean focussing upon the retina the image of the object to which the eye is directed.

By many direct experiments I have found the following changes to take place in binocular vision when directing the eyes from a distant object to a nearer one:—1. Both eyes turn inwards, until their axes cross exactly at the point where the object of attention is situated. 2. The iris of each eye contracts. 3. The ciliary muscles acting upon the crystalline lenses cause them to become more convex, and, consequently, of a shorter focus.

The reason for such changes could be easily accounted for; but as the object of this article is to describe an instrument with which these changes may be demonstrated, I shall not attempt their explanation here.

The accompanying illustration, Fig. 1, shows the plan of an instrument which I venture to think would prove of some service in science schools for the purpose of teaching the laws of binocular vision.

I will first describe the instrument itself, and then refer to its teaching capabilities. The base on which the model is mounted consists of a polished mahogany board about ¼in. thick, and

bevelled off at the edges. Four brass balls screwed to the underside form the legs (one of these is shown at S, Fig. 3). Two discs of thin brass, L and R, Fig. 1, represent the two eyes, and these revolve on centre screws, P P, fixed to the board. Six wires are then employed to represent oblique and direct rays of light entering the eyes; these wires also turn on the centre screws P P. To each of the outer wires—i.e., those representing the oblique rays, a metal arm,

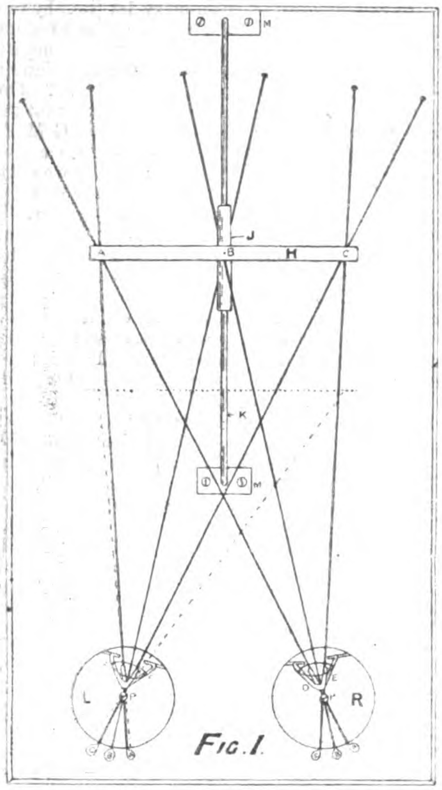

FIG. 1.

as shown at D, is soldered, the object of which is to represent the inner portion of the iris in each case—viz., in the right eye R, the metal arm D is soldered to, and works in unison with, the wire representing the oblique rays emanating from C, whilst the arm E works in conjunction with the oblique ray proceeding from A. The other portions of the iris extending to the circumference of the discs is painted upon the metal. The crystalline lens is represented by thin steel wire, fixed at F F, left eye L. It will be seen that the wires forming the rays extend, in both cases, to the circumference of the discs at the

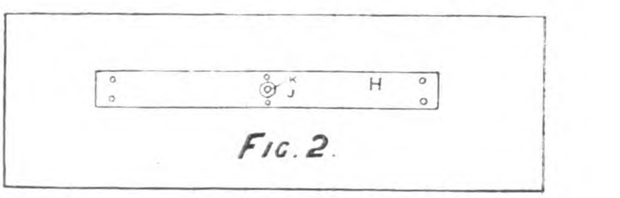

FIG. 2.

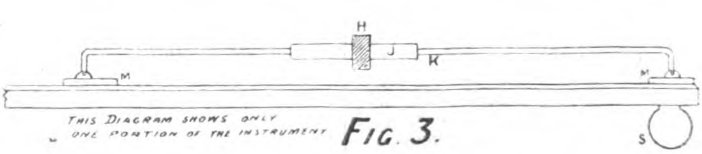

FIG. 3.

back, after being once wound around the centre screws P P.

The object to be examined by the eyes is shown at H, and consists of a beam of hard wood pierced with six holes (see Fig. 2) and fitted with a tube, J, at the centre. The movement of this beam is controlled by a steel rod, K, Fig. 1, passing through the centre tube J, and supported in the manner shown in the side view, Fig. 3. As will be seen by reference to Fig. 3, this arch-shaped steel support acts as a guide for the beam of wood, and keeps it from touching the surface of the board. Such an instrument may be called an automatic instructor, for we may slide the object H to any distance within the range of the instrument, and the mechanical changes that take place have a fair correspondence with those which the human eyes undergo during their movement and accommodation called for in binocular vision.

Now in reference to its teaching capabilities. Let the student suppose the observer to be looking at an object situated at A, the axes of both eyes will meet at that point, as indicated by the present adjustment of the instrument. On bringing the object A nearer to the eyes until it reaches the dotted line, the following changes will take place. Both eyes will turn inwards, revolving on P P. The oblique wires will diverge, and the size of the supposed image upon the retina will become larger, as indicated by the dotted lines in the left eye L. The irises will have contracted, whilst the crystalline lenses will have become more convex. On shifting the object H to the end of the slide, so that it is further from the eyes, the order of these changes will be reversed. The eyes will diverge their axes, the image space upon the retina will become considerably smaller, whilst the irises will be dilated and the crystalline lenses flattened. Hence the apparatus will demonstrate to the student axial movement and accommodation, such as binocular vision demands.

Theodore Brown.

THROUGH A SMALL TELESCOPE.—III.

By Norman Lattey.

The most striking constellation in the Northern heavens is, of course, Ursa Major (The Great Bear) and as it happens also to be circumpolar—i.e., continually above the horizon in these latitudes, it will be as suitable a group as any with which to begin our examination of stellar objects. At present it hangs immediately over the northern sky line like a great note of interrogation, its two "pointers" directing the eye to Polaris the polar star, situated in Ursa Minor (the Little Bear). A reference to the star atlas and planisphere recommended in our first paper will enable the reader to easily identify these constellations by their principal gems. In the formation in Ursa Major known as "Charles' Wain," is to be found the star ζ Mizar, the most beautiful double in the heavens. The primary is of second magnitude and greenish-white with a brilliant companion 4½ magnitude. At some little distance—on the margin of the field of view with a power of 60 diameters—will be noticed another star, Alkor, and several fainter ones, the whole assemblage on a dark clear night presenting a glorious spectacle. The visibility of Alkor without optical assistance is considered a test of eyesight.

Around the star β Ursæ Majoris are scattered several interesting planetary nebulæ, so called on account of the planet-like discs they exhibit. The largest (number 2343 in Klein's Atlas, and commonly known as the "Owl Nebula") is 2′ 40″ in diameter. A low-power e p. shows it best; but the sky must be dark, clear, and free from veiling mists. Spectroscopic analysis pronounces it to be a globular mass of glowing gas, within the limits of which probably thousands of solar systems could be comfortably accommodated.

Following the line of the "Pointers" in Ursa Major (see first illustration), the Polar star will be soon met with. It is the most important unit in Ursa Minor (the Little Bear), for around this twinkling point of light the entire vault of Heaven appears to circulate in stately revolution. The effect is, however, merely optical, being due to the circumstance of Polaris being situated almost vertically over the terrestrial North Pole. As will be explained further on, the unique position occupied by the present Polar star is of comparatively recent occurrence—at least, as far as this particular object is concerned, and even now the star does not *exactly* mark the celestial pole, its actual position being about a degree and a half from it. A good 3in. will discover the tiny companion. Keen-sighted observers have glimpsed it with a 2in., and even less. The spectroscope has lately revealed a triple system, but so exceedingly faint are the components that even the mammoth Lick refractor fails to show them. It is calculated that the light of Polaris, travelling at 186,000 miles a second, takes sixty-three years to reach us.

Towards the north-west lies Hercules, preparing to set. Between the stars η and ζ is situated the celebrated Cluster—a magnificent agglomeration of glowing suns. On a clear night it is just visible to the naked eye as a light cloud, and of course easily discernible in the smallest telescope. A 4in. will readily show its stellar nature, and in larger instruments it presents an amazing spectacle, especially when it is remembered that the luminous ball the observer is gazing at is composed of over two thousand blazing suns, each far exceeding the brilliancy of our own luminary.

α Herculis is a fine variable star of the 3rd mag., orange-red in colour, with an emerald-green companion. δ Herculis, another pretty double, has a greenish-white primary and bluish companion, farther off than in the last case. As it is rather late in the season to see Hercules at its best, observations should be commenced as soon as possible after dark.

Almost due west, glittering rather higher up, will be noticed a particularly bright star flashing its scintillating rays of steely blue, like a miniature arc lamp. This is Vega, the chief star in Lyra (the Harp). Many thousands of years ago it enjoyed the post of honour now held by Polaris; but, owing to the wobbling of the earth's axis in a slow and steady gyration, like the peg of a spinning-top, Vega has been compelled in its turn to make way for all the other stars which lie on the imaginary circle traced out by the earth's pole upon the sky. Any elementary work on astronomy will quickly make this rather abstruse subject more intelligible. The distance of Vega from the Solar System is placed at 93 light years; in other words, the star may have ceased to exist nearly a century ago, but the last ray of light that left it cannot yet have completed its journey across the inconceivable gulf that separates us. Vega is surrounded by a number of smaller stars, but their connection is purely optical. They are obviously not members of a multiple system.

Close to Vega is an exceedingly interesting pair of twin stars, ε^1 and ε^2 Lyræ, known as the "Double-double." Here we have a duplicate system of four suns, the individual members of each couple revolving round one another, as well as each of the pairs round a common centre of gravity. β Lyra, a yellowish-white variable, is well worth scrutiny. It waxes and wanes at intervals of nearly thirteen days, the diminution ranging over an entire magnitude. It has three tiny companions visible in a small telescope, but only under specially favourable conditions. Between β and γ Lyræ can be detected the famous Ring Nebula. It is, however, a disappointing object in all but instruments of large aperture. Still, it can be caught with a 2¾in.—probably less—as a circular collar of faint luminosity somewhat resembling a ship's lifebuoy. In giant telescopes this curious ring of brightness sparkles as if composed of stellar points.

In the direction of the west, about midway between the horizon and the zenith, stands the constellation Cygnus (the Swan), its principal stars in the form of a great upright cross. Amongst the most interesting objects contained in it is β Cygni, a reddish-yellow star of the 3rd mag., with a small blue companion. It is one of the loveliest pairs in the starry heavens. The star numbered 61 Cygni, though comparatively small and otherwise scarcely worth attention in a small telescope, has a decided claim to the student's notice. As far as can be ascertained, this, with the exception of α Centauri, in the Southern hemisphere, is our nearest stellar neighbour, one of the first outposts of an infinite universe of suns. Yet so remote is it that its light takes seven years to travel to us. It is likewise double, with two golden-yellow components of 5th and 6th mag. Between α and δ Cygni is situated a

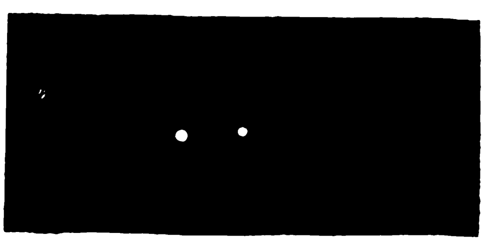
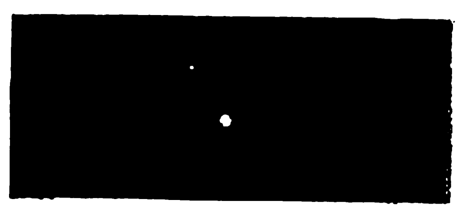
ϵ^1 and ϵ^2 *Lyræ*. The Double-double.



β Cygni.



α *Ursæ Minoris*, the Polar Star.

rich star cluster; and two more, rather fainter groups, lying further north.

Immediately below Cygnus is the minor constellation Vulpecula (the Little Fox), containing the well-known "Dumb-bell Nebula." A 4in. shows this object tolerably well, but it can be discerned with a much smaller instrument, although by no means easy to pick up. Spectroscopic analysis reveals it to be composed of vast clouds of incandescent gas.

Below Vulpecula glitters Altair, the major brilliant in Aquila (the Eagle), a splendid star of the 1st mag., with a minute companion of the 10th mag. The latter is, however, far beyond the reach of anything under 5in. or 6in. aperture. β Aquilæ, the lowest of the three stars lying in an almost straight line (of which Altair is the middle), is of the 4th mag. and pale red, surrounded by several fainter specs; but none of them are of special interest.

Space now compels us to suspend operations. After next week, if the weather permits, we will commence our examination of the moon's wonderful surface; but it will be impossible to deal with more than a few of the most striking features on the "terminator," that sharp line of demarcation between night and day on the lunar disc. Several sketches will be made throughout the entire lunation, chiefly for the purpose of identification, in order to enable the student to more closely scrutinise them for himself when the corresponding phases occur again subsequent to the next "new." The writer cannot, however, hope to portray more than a tithe of the delicate and intricate detail revealed by the perfect 4in. photo-visual refractor by Messrs. T. Cooke and Sons, of York, which is being used stopped down to 3in. When the full aperture or less than 3in., is employed, the fact will invariably stated.

In the mean time the student cannot be strongly urged to carefully note and report any changes he may detect in star tints, or evidence of varying brightness. Comparisons with neighbouring stars will facilitate work in the latter department, and when the case appears beyond doubt it can be submitted to more powerful optical assistance for confirmation.

SOME METEOROLOGICAL INSTRUMENTS AND THEIR USES.—X.

INTERESTING as it is to know how much rain has fallen during the day, month, or year, it is of no less importance to know the quantity that falls in an hour or portion of an hour. As already remarked, it does not entail a great deal of labour on the part of an observer to procure a daily record of the rainfall; but an hourly visit to the rain-gauge is out of the question, and if it be desired to secure a continuous record it therefore becomes necessary to obtain instrumental aid. As regards yearly averages of rainfall, not the least of the advantages gained by a perusal of such figures is that it enables much to be learnt concerning the suitableness or unsuitableness of certain parts of the world for agriculture and such-like operations. Thus it has been concluded that when the mean annual rainfall is less than 18in. agriculture can only be carried on by means of irrigation, and when the fall is below 12in. cultivation of the soil becomes extremely difficult, if not altogether impossible. Such figures also indicate that mankind has been most successful in agriculture in those localities where the rainfall is distributed evenly throughout the year, the most profitable results being associated with those areas over which the annual rainfall is from 50in. to 80in. It is probable also that had more complete information been forthcoming concerning the regimen of the rainfall in certain distant parts of the world, speculators would have been restrained from embarking on enterprises in localities having unfavourable characteristics as regards their rainfall. The rain gauge therefore may be made to point out the most suitable routes to be taken by an onward-moving empire. Many similar questions to the foregoing may be discussed in the light of rainfall observation, while more detailed records such as are obtained from self-recording rain-gauges admit of the daily history of the rain-fall being more minutely examined and given a long series of observations; it is possible to discover what hours of the day are most rainy, and to learn much concerning the duration of heavy showers, and the times and seasons when unusual falls are most frequent. So many people and occupations are affected by rain that there will be no necessity to enlarge upon the many benefits to be derived from a knowledge of the most suitable hours for taking one's walks abroad and for engaging in outdoor pursuits. For the agriculturists, engineers, and sanitary authorities, such information is of obvious interest. A self-recording rain-gauge, therefore, will give a great deal of interesting detail, and there are few meteorological instruments which so well repay attention.

Seeing that self-recording rain-gauges must necessarily be in the open air, considerable skill is required to adjust the working parts of them so that they shall not be thrown out of gear by changes in the weather. The clock, for instance, which drives the cylinder upon which is put the paper carrying the automatic record, requires to be of good workmanship, and demands considerable attention to preserve it from being affected by the dampness by which it is surrounded. In these instruments the collector, or outer portion of the gauge into which the rain first falls is very similar to that of other gauges, and similar precautions have to be taken to avoid insplashing of rain drops, and to keep snow from blowing out once it has fallen into the gauge. Now, in order that the amount of rain which falls from hour to hour may be determined, it is necessary to allow it to run out of the collector into a smaller vessel, sometimes called a receiver, so that the rate at which this latter fills and empties itself may be made to indicate the heaviness of the showers. In very many of these gauges the receiver is emptied by a small siphon of the kind commonly called intermittent. As the water flows from the outer part of the gauge into the receiver, it ascends the short leg of the siphon and drives the air before it and down the longer leg until, as the water rises, it presently reaches the bend in the tube, which is somewhat flattened, and falls over into the longer leg, and brings the siphon into play. By this simple contrivance the receiver is rapidly emptied immediately the water arrives at a definite height, and with it there is no interruption of the record by air bubbles lodging in the bend of the siphon, and the flow of water is not retarded.

Supposing, now, that the area of the collector is 100in.; the rain, as it falls, may be led by a funnel into a small glass or copper receiver having a capacity of 20c.in., so that, every time the receiver is filled, it indicates that two-tenths of an inch of rain have fallen. Moreover, if this receiver be supported by a small column running between small friction rollers and floating in a cistern of mercury, it will descend as the weight of water in it increases, and as soon as the water is discharged by the siphon it will quickly float upwards again. All, therefore, that has to be done to secure a continuous record is to attach a pencil to the outside of this moving receiver or float, which may be so adjusted that a mark or trace may be impressed upon the strip of paper wrapped round the revolving cylinder. Commonly, this strip of paper, which needs to be waterproof, contains the record for one day only, although it may be arranged for a longer period; and since it is ruled into hour spaces, it is easy to learn how many times the float fell and rose during the day, and so determine the amount of rain for the whole period. Occasionally, during heavy showers, the float may descend several times during the hour, and the full particulars of the rate at which the shower came down will be clearly shown by the perpendicular lines traced by the float and the pencil as they rose and fell together.

The water which is discharged from the receiver is, of course, carried off by a suitable pipe, and has no further interest after it has depressed the float. There are, however, other forms of receivers and other methods of discharging them, a very common variety taking the form of what is termed a "gravity bucket." These gravity buckets consist of a small vessel divided into two portions by a slip of metal or other material, which is so placed upon an axis as not to be exactly balanced, and in such a way that one end or the other is uppermost. The rainwater is conducted alternately into the two halves of the gravity or tilt bucket, and as one side is being depressed by the weight of water flowing into it, the other is turning upwards and getting into position to receive its load of water. As soon as the bucket reaches a certain point in its downward course it tips completely over, and the water is at once discharged and flows away down a small waste-pipe. Each division of the bucket holds a known quantity of water, which is proportional to the collecting area of the gauge, so that each discharge represents a certain depth of rain, and supposing the collecting area to be 200in., and the capacity of the division in the bucket 50c.in., the indication is that a ¼in. of rain has been collected. In some forms of this rain-gauge the water first passes into a receiver and flows thence into the gravity bucket, and the tilting of this latter, which is adjusted in a glass globe, creates a partial vacuum every time it tips out the water, and in this way a small siphon is put in action, and the flow of water from the glass globe to the bucket maintained. Having thus succeeded in putting the bucket in motion, it is a comparatively easy matter to harness a pen or pencil to it, by means of a spring or pulley, and register the rate and time of its movements on a strip of paper in the usual way.

These self-recording rain-gauges require constant attention to keep them going, and considerable skill is necessary so to construct them that the float, siphon, gravity bucket, pen or pencil, and the clockwork shall all work smoothly and continuously, and not get out of order during heavy rains, when the strain upon the resources of the instrument are greatest. There are, however, simpler methods of construction, and, although they are not quite so suitable for strictly scientific purposes, they nevertheless admit of very useful instruments being made by their aid. One such method consists in having a series of bottles or receivers arranged to hold the rain which runs from the outer portion of the gauge, each bottle representing a certain hour of the day. By this method of construction the collecting portion of the gauge is connected with a clock and revolved, so that if a pipe runs from the lower portion or funnel of the gauge it may be made to pass over the bottles in succession, and at an even rate. The bottles are arranged, of course, in a circle, and if the gauge is visited twice a day a series of twelve could be made to represent the twenty-four hours of the day. If, therefore, each bottle is properly graduated, all that needs to be done to ascertain the amount of rain that fell during each hour of the day is to measure the contents of each bottle, while the different amounts added together give the total value of the catch for the day. Now in such an arrangement as this, there is always a danger that some of the rain may be lost, owing to faulty construction of the small pipes that are required to distribute the water; and there is further always a possibility of outside moisture finding its way into the various bottles. The greatest source of loss is, however, commonly by evaporation, and in all gauges special devices are necessary to prevent water escaping by this facile road. Possibly, if the bottles were constructed after the manner of certain ink-pots, which have a cone-shaped depression for a mouth, and are designed to prevent loss of ink by evaporation and other untoward circumstances, deterioration of the rainfall records would be decreased.

During times of frost also the bottles would need watching lest the water within them should freeze, and they be destroyed. But the most troublesome circumstance to deal with is snow, for it not only chokes up the gauge, but since it can only be melted at certain times of the day, it becomes impossible at times to say when the snow fell, and how much of it should be apportioned to the individual bottles. All that can be done at such seasons is to melt the snow by pouring hot water upon it, and determine the amount for the whole day and take no regard for the hourly values. In measuring this melted snow care must, of course, be taken to deduct the hot water that has been added, which should always be a known quantity. In some gauges the attempt is made to melt the snow at once as it falls, this being done by keeping a jet of gas burning beneath the gauge; but, as a rule, this adjustment entails more attention than most observers are willing to bestow. Under ordinary conditions, however, the arrangement of bottles should be managed without much trouble, and since the construction of the necessary apparatus does not require more than ordinary mechanical skill it is to be recommended. It may also be observed in passing that this arrangement of bottles may be made to secure a continuous series of observations concerning the wind and the rain, and the points of the compass from which the rain comes. In this case the gauge is put in connection with a wind vane, and turns about with it, and the bottles are arranged to represent the points of the compass. As before, the rain would be led from the collecting surface of the gauge to the various bottles by a small protuding pipe, and measurements once a day would, when added together, not only tell how much rain had fallen, but also how much was to be set down to the credit of each direction of the wind. Now although such a gauge as this could not be expected to have the precision of registration attained by more elaborate instruments, there is a simplicity about its parts which urges the mechanically-minded to attempt its construction.

From a continuous record of rainfall many combinations of means and averages may be obtained, and, in addition to learning the time of the duration, beginning and ending of individual showers, hourly, daily, monthly, and yearly averages are to be worked out. Unfortunately, the compilation of such averages entails considerable arithmetical drudgery, and observers who are willing enough to set up rain-gauges and attend to them regularly, are inclined to shirk this part of the business. Before also this part of the work can be attacked, the curves or traces obtained from self-recording instruments have to be measured, or tabulated as the term is, with appropriate scales, and this operation also demands a large amount of enthusiasm for its successful accomplishment; but until this measuring and adding up is performed, the records remain meaningless, and the only safe method in this, as in other mundane affairs where work quickly accumulates, is to do a little each day; and if, as each rain-record is removed from the instrument it is at once tabulated, there need be no fear of a rising tide of arrears. Now, as regards the number of years' observations required to give a good average representation of the rainfall in any locality, it is probable that to obtain a yearly average at least ten years are necessary, and if it be desired to obtain dependable monthly averages at least thirty years are advisable, for the fluctuation in the monthly rainfall is often very large. A note of the maximum amount of rain which fell during the individual months and years is of interest, and these figures are, of course, picked out from the records without much difficulty. Further, the number of rainy days should also be extracted for each month, and in this connection it may be remarked that meteorologists call a rainy day one on which ·01in. or more of

rain was measured, and, as already mentioned, no regard is taken of the form of the precipitation —hail, snow, and moisture from dew, hoar-frost, and fog being all counted as rain. Having obtained these figures, it is then possible, if the series of observations is long enough, to calculate the average number of rainy days for any desired period, and, in estimating the probabilities as regards the future supply of rain-water, these and similar figures will greatly assist the observer to arrive at right conclusions.

NOTICES OF BOOKS.

The Prevention of Factory Accidents. By JOHN CALDER. London, New York, and Bombay: Longmans, Green, and Co.

THE author of this work has been for some time an inspector of factories, and being also a Whitworth scholar, it may be presumed that he has both knowledge and experience of the subject on which he writes. The first portion deals with the statistics of casualties, and the third part with the law on accident and safety in factories, both of which may be studied with advantage by both employers and employed. The second and more useful portion of the work is devoted to the prevention of accidents. Some of the statistical tables will be studied with attention by, amongst others, the friendly societies and assurance offices, and those portions which deal with the law on the subject of compensation will attract the attention of trade-union and other societies. The author gives some cases of accidents due to ignorance on the part of the workers; but the principal causes are carelessness, insufficient lighting, defects in machinery, and unsuitable clothing. There are parts of machines which cannot be fenced, because it is necessary for the operator to approach them closely, and then ragged sleeves, loose jackets, slipping neckties, and in the case of females, long hair unconfined, are prolific sources of accident. The chief cause of accidents in factories (an inclusive term) is, however, the absence of safeguards; but, thanks to recent legislation, and the vigilance of factory inspectors, that risk is being gradually diminished. The illustrations (124) are natural, confined to the sections which deal with the prevention of accidents, and they should be specially useful to owners of factories wherein many persons are employed.

Steam-Engine, Theory and Practice. By WILLIAM RIPPER. London, New York, and Bombay: Longmans, Green, and Co.

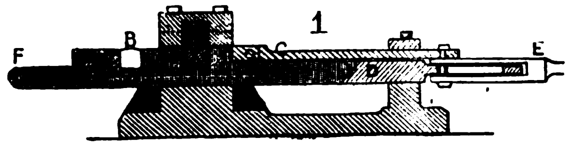
THE author of this work is the Professor of Engineering in the University College of Sheffield, and has issued this book as a sequel to his elementary treatise on "Steam." Special attention has been given to the subjects connected with the heat quantities in the generation and use of steam, and the temperature-entropy chart of Capt. Sankey forms the frontispiece. Mr. Ripper has brought his work up to date, and has included notes on all the modern types of steam-engines, on compounding, superheating, valve-gears, governors, &c. The chapters on friction, balancing, and on the modern "quick-revolution engine" are worth attention, and the work may be commended to all students of steam and the methods of its utilisation through mechanical apparatus.

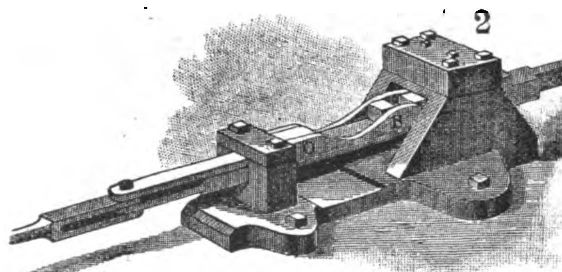
The Modern Safety Bicycle. By H. A. GARRATT. London: Whittaker and Co.

THE author says his work is intended to help riders to understand their machines rather than to assist manufacturers, and although some of the latter may be mentioned rather frequently, it must not be supposed that those firms whose names are not mentioned are really less important. Referring to the "free wheel," Mr. Garratt says he uses the word "pedals" instead of "wheel," which term he says many people do not understand—as a matter of fact it is not correct. The frontispiece is an illustration of part of the workshops of the Northern Polytechnic Institute in the Holloway-road, of which Mr. Garratt is the head in the engineering department. The volume is freely illustrated, and there are five working drawings. The "safety" type is the subject, but there is a great deal of information in this work which will be especially useful to riders and those who wish to thoroughly understand the construction of modern cycles. All cyclists will read this book with pleasure, for even if they do not always agree with the author in his criticisms, they will at least find food for thought in them.

We have also received *Practical Cycle Repairing* (London: Office of *Ironmongery*), a collection of articles which have appeared in that serial, and which are intended to help those who may be called upon to repair cycles.——*The Wonders of Modern Mechanism*, by CHARLES HENRY COCHRANE (London: J. B. Lippincott Company), is the third edition of a freely illustrated work in which the author has endeavoured to present to the public in popular language the results obtained with modern mechanical devices in all branches of science. It is a very interesting work.——*Practical Engraving on Metal*, by G. A. BANNER (London: Hampton and Co.), is intended for amateurs who occupy their leisure in carving, saw-piercing, inlaying, &c. It is a practical work, and will be found useful by all interested in "engraving"—a term which covers a great deal.—— *Wood-Carving for Beginners* and *Decorated Wood-Work* (London: Dawbarn and Ward, Ltd.), by CHARLES GODFREY LELAND and C. E. DAWSON, belong to the "Useful Arts and Handicrafts Series" issued by the publishers. They are freely illustrated, and will be found instructive by those who wish to do work of the kind.——*The Elements of Co-ordinates Geometry*, by J. H. GRACE, B.A., and F. ROSENBERG, M.A., B.Sc. (London: W. B. Clive), is one of the works published in the University Tutorial Series. It is Part II., and deals with "The Conic," a subject of interest to mathematicians. It is of value to students and to candidates for the London B.A. examination, more particularly those who have to study at home.——*Euclid's Elements of Geometry*, edited by CHARLES SMITH, M.A., and SOPHIE BRYANT, D.Sc. (London: Macmillan and Co., Ltd.), is a well arranged school edition of Euclid.——*Monthly Star Maps for the Year* 1900, by WALTER B. BLACKIE (The Scottish Provident Institution), is a series of star maps for the northern and southern aspects of the heavens in these islands. The charts are hemispherical on plan, and printed in blue with the stars in gilt. The time selected is 10 p.m. on the first of each month. Star maps of this sort are very useful in teaching the observation of the sky.

HANEY'S SAFETY SWITCH-LOCKING MECHANISM FOR RAILWAYS.





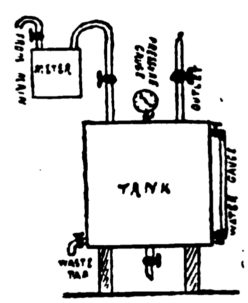
AN invention has been patented by William Haney, of Lexington, Kentucky, which provides an ingenious means for opening and closing railway switches and for locking the switch tongue in its adjusted position, to prevent possible accidents.

The switch-operating mechanism comprises a shifting-bar, F, formed with two transverse notches, in which a spring-pressed locking-bar, A, is designed to engage. At opposite sides of the shifting-bar, cam-plates, B, are arranged, which are curved so that their highest points are on a plane with the top of the shifting-bar. The cam-plates, are connected by means of a link, C, with an operating rod, E, leading to a switch-tower, and can be moved independently, and with the shifting-bar. The link C is connected with the rod E by means of a bolt passing through a longitudinal slot in the shifting-bar.

When the locking-bar A is in the first notch, as shown in Fig. 1, and it is desired to shift the switch-tongue in an opposite direction, the rod E is pulled outward, thus drawing the cam-plates, B, longitudinally, and causing the curved portions to raise the locking-bar A against its spring. During this motion the bar will remain stationary, because the bolt connecting the rod E and the link C is travelling in the longitudinal slot of the shifting-bar; but when the bolt reaches the end of the slot, the cam-plates and shifting-bar will be drawn together, until the locking-bar moves into the second notch, thus locking the switch-tongue in adjusted position. The movements are reversed when the parts are shifted to their first position. Since the boxing in which the locking mechanism is contained is covered, the parts cannot become clogged by snow, ice, or dirt.—*Scientific American.*

LARGE ILLUMINATIONS.

IN the course of an article on this subject in *The Optical Magic Lantern Journal*, Mr. G. W. Nash says:—There is a method by which we can use coal-gas under pressure from the main without resorting to an injector jet. A good water-pressure from the main is required, and, of course, gas must be laid on. Now, suppose you have a large closed tank of the necessary cubic capacity, connect this underneath with the water-main, and at top with the gas-main, and let each connection throughout be provided with its own tap. A tap is also required below to let out waste water after using the gas. In order to see the quantity of water and gas in the tank, a water-gauge should also be fitted. A tube fitted to the top of the tank serves as an outlet for the gas, as shown in the illustration. The tap from



gas-main must always be kept carefully turned off while using gas from the tank. Now, suppose we have the tank filled with water, and desire to fill it for use with gas, turn on the gas at the meter, and then open the outlet for waste water, having all others closed. It is evident that the water will gradually leave the tank, thus enabling the gas to supply its place. The tank being full of gas, which is ascertained by the gauge, we close the water waste, and then turn off at the meter. If we now turn on the water at the main we have the pressure below the gas, and can use it at a pressure varying with the force given by the water. A pressure-gauge should be used also to show the pressure we are dealing with, as, of course, the oxygen supply must be carefully regulated to balance it. A container could be used for the oxygen, and the gauge carefully watched, to prevent the pressure becoming too high. Very careful attention to all the details should be given, as they are necessary to proper working. These remarks will show the reader that a considerable amount of unusual apparatus is needed in this work, and the cost must be counted beforehand. In the limelight arrangements at the Empress Theatre, alluded to above, instead of the ordinary light-box being used, the light is concentrated by reflectors, which consist of a bowl of copper, silvered and suitably mounted, with the jet

in front; the incandescent portion of the lime facing the reflector, and not the surface to be illuminated. The limes used (often) are what are known as "cup limes," having no central hole for the pin, as we usually see. They are also longer than those in ordinary use.

HOW A BIRD SWIMS UNDER WATER.*

IT is a rare sight to see a bird swim under water, and one which but few are privileged to witness, yet by care I have watched the bird in its movements under water on two occasions, and will give my readers a description of the act. If I were to give the proper heading to this article, I should head it, "How a Bird Flies Under Water," for on these occasions the birds were scared and trying to escape, and their movements took the nature of flying rather than those of swimming.

Once I headed a Pied-bill Grebe, so that it was cut off from the deep water, and it had to pass through a strip of shallow water in order to get back into the pond, and very near to my position in a boat. The position of the bird was almost exactly as in flight, and the neck was stretched out to its full length. The legs, placed far back, as with the divers, were used as paddles, or, as we might say, as propellers to the craft, while the wings, partly extended, were beating the water in the efforts of the bird to escape. I am fairly satisfied that the bird secured as much power from its wing movements as from its feet. It went through the water like a fish.

At another time I was hunting whistle-wings or golden eyes on the river, and succeeded in heading one off in its efforts to escape, and by rushing up kept it from following the rest of the flock, and made it seek protection beneath the surface of the water at the hole in the ice on the river. The strip of water was about one hundred yards long, by ten or twelve wide in the centre, and gradually narrowing at each end, and was kept open by the rapid current of the stream. These spots of open water are generally to be found on Michigan streams even in the coldest weather, and are often occupied by the winter ducks and red-throated divers. The water was not over a foot and a half deep in the shallow places, and less than a yard throughout, and I could plainly see every movement of the duck as it literally flew through the water. Its feet moved as paddles, alternately and with great rapidity. But the wings were also used as a means of propulsion, and I think that a greater impulse was derived from this means. The motions of the wings were combined as in aërial flight, but were spasmodic, and the bird seemed at times to be actually flying in the water. The wings were but partially spread when the bird swam. Sometimes an unusual burst of speed would be made, as the wings, through an extra effort, were beaten with greater rapidity—much in the same way that a fish makes a sudden dash by powerful tail strokes.

All this time I was walking, or rather trotting, along the edge of the strip of water and trying to get a good shot at this duck, or rather drake, for it was a full-plumaged male. He rose often enough, but did not remain above the surface the length of a second, and I honestly do not think that the quickest shot in the world could have shot that diving whistle-wing, even with the privilege of trap rules, and could he have said, ready, pull. Talk of greased lightning, and of loons diving at the flash! I took several shots at that bird, as I followed up and down the strip of water, but I do not think I touched him, and I much doubt if any other man could have hit the bird as long as it had strength to dive and swim.

Up and down we went, the bird swimming, or, rather, flying, in the water, and I trotting along and loading my gun. The duck would turn back when it reached the end of the strip of open water, and dash by me, often within ten feet, and make for the opposite end, and at these times I could see the swimmer to perfection as he flew by me under the surface.

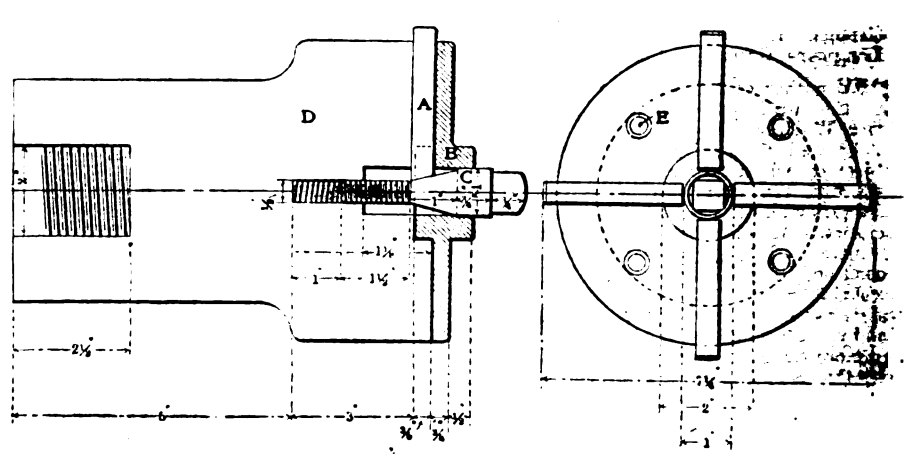
All at once I missed his drake-ship at the lower end of the opening, and, after waiting several minutes, concluded that the crafty fellow had been swept under the ice by the swift current and hurried to destruction. This may have been the case, but it is quite possible that the bird intentionally dove and made the distance to the next open space, a very small air-hole fifty yards or more below. There is no reason to doubt that the bird could do this after what I had seen. A companion with whom I was hunting came up soon after and strengthened the opinion, for he had heard wings below and had seen a bird fly from the lower hole, and he said that he was quite sure that there was no duck on the hole the moment before his attention was attracted.

I have had entire flocks of teal dive at a flash, have chased wounded ruddies, blue-bills and buffleheads, and have wasted my time and powder on mergansers, hell-divers, and loons, but these all had plenty of water and a chance. But here was a case where a bird could not be hit even in circumscribed quarters, and though too wise to seek escape by flight, yet had the impulse to dive, and finally to take the risk of passing under a stretch of ice and effecting its escape. At no time was this bird at a greater distance than 50ft., and often scarcely more than 10ft., from me.

* By Morris Gibbs, M.D., in *Popular Science*, N.Y.

AN ADJUSTABLE BORING TOOL.

THE following illustrated description of an adjustable boring tool is contributed by Mr. J. F. Morgul to the *American Machinist*. The designer says it is one that he has just completed



for his own use. The body D of the tool is of cast iron, and a taper shank, not shown, of machinery steel is screwed into the back, and enables it to be used on any boring mill or large drill as required, The cutters are of $\frac{1}{2}$in. square self-hardening steel. and the grooves in the face of the stock D should be milled only $\frac{13}{32}$in. deep, so that the steel plate B, which is held by four countersunk head screws, will properly bind them. The central screw with the conical bearing against the inner ends of the cutters gives nearly $\frac{1}{8}$in. adjustment, either for wear or for different diameters of hole, the size of tool here shown being $7\frac{1}{4}$in. It may, of course, be made with two, four, or six cutters, and the adjustable feature of it, and the ability to change the cutters for other bores, make it a handy and valuable tool.

A MILLING RIG FOR A LATHE.

IN one of the shops in which I worked a number of years ago we had some peculiar packing rings for piston-heads. The joints were milled so as to fit together and make a tight job, or at least that was the intention, says Mr. R. E. Marks in *Locomotive Engineering*, N.Y. These joints could not be handled very well on a milling machine, and as we were not blessed with a decent one anyhow, we were not troubled on that score. One of the ingenious chaps rigged up a fixture like the sketch, which was put on an 18in. lathe when it was needed, and it made a very handy rig for the work. The upright F, shown in Figs. 1 and 2, fitted the ways of the lathe, and was well supported; it had a vertical slot, as shown in dotted lines, so as to allow for different radius rings. There were separate front or springing pieces for each size, each within a worm thread cut on edge for feed, and a lip, *l*, for supporting work. This swing-arm faced the lathe-spindle, and the cutter *c* did the work.

It would have been easy to connect the swinging arm to a nut on the screw by a link, and then make one arm do for all sizes by blocking up to hold the work. This can be figured out by whoever wants to use it.

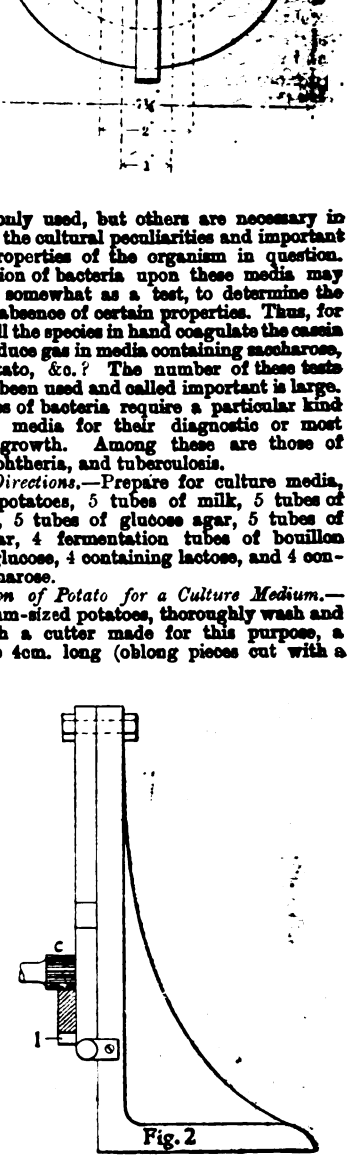

Fig. 2

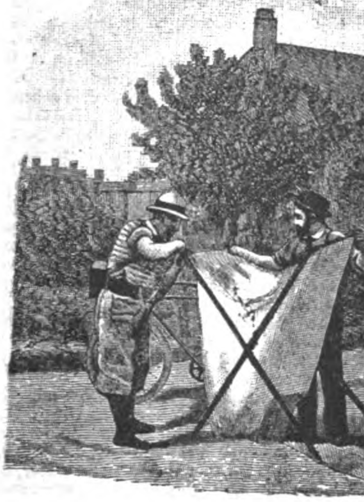
PREPARATION OF CERTAIN SPECIAL MEDIA.*

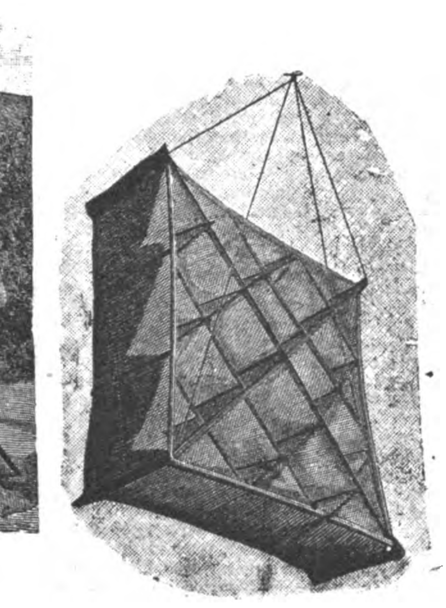
IN studying the properties of bacteria it is desirable to cultivate them on a number of different media. Bouillon, agar, and gelatin are most commonly used, but others are necessary in determining the cultural peculiarities and important biochemic properties of the organism in question. The cultivation of bacteria upon these media may be regarded somewhat as a test, to determine the presence or absence of certain properties. Thus, for example, will the species in hand coagulate the casein in milk, produce gas in media containing saccharose, grow on potato, &c.? The number of these tests which have been used and called important is large. A few species of bacteria require a particular kind or kinds of media for their diagnostic or most differential growth. Among these are those of glanders, diphtheria, and tuberculosis.

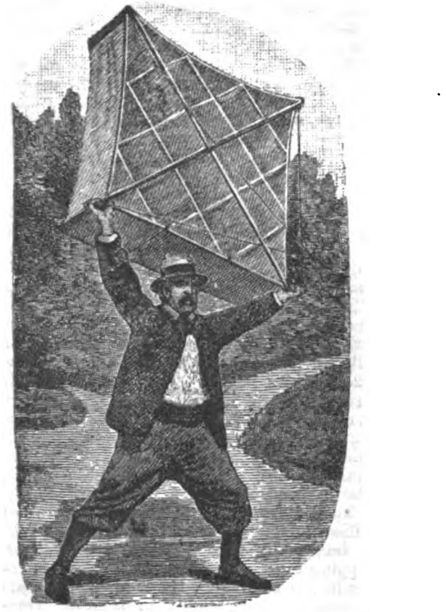
General Directions.—Prepare for culture media, 5 tubes of potatoes, 5 tubes of milk, 5 tubes of litmus milk, 5 tubes of glucose agar, 5 tubes of glycerin agar, 4 fermentation tubes of bouillon containing glucose, 4 containing lactose, and 4 containing saccharose.

Preparation of Potato for a Culture Medium.—Select medium-sized potatoes, thoroughly wash and cut out with a cutter made for this purpose, a cylinder 3 to 4cm. long (oblong pieces cut with a knife will do quite as well). Ordinarily two cylinders can be cut from each potato. The inclined surface is obtained by cutting out the potato projecting above the frame of the cylindrical knife. All of the skin must be removed. Wash the potato cylinders in cold, running water for some five minutes (a longer time is preferable), and place them in test tubes of the proper size (large or small according to size of cutter used), and add about 1c.c. of water to each tube. Sterilise them by discontinuous boiling or steaming for twenty minutes

* By V. A. Moore, in the *American Monthly Microscopical Journal*.







each day for three consecutive days. Wipe, label, and store.

Preparation of Milk for a Culture Medium.—Place about 100c.c. of fresh milk in a beaker in the ice box, and allow it to stand for from 10 to 15 hours. Then carefully remove all the cream. It is well to filter the milk through a thin layer of absorbent cotton to remove any masses of cream. The reaction should be tested, and if strongly acid it should be rejected or made 1·5 per cent. acid to phenolphthaleni by the addition of n 1 sodium hydrate. Distribute the skimmed milk in small test-tubes (7c.c. in each), and sterilise by discontinuous steaming in the same manner and for the same length of time as the potatoes. Label and store in locker.

Preparation of Litmus Milk for a Culture Medium.—This is prepared the same as the milk medium with the addition of enough of an aqueous solution of litmus to impart a decidedly blue colour to the milk. Sterilise, label, and store the same as the milk.

Preparation of Glucose Agar.—Prepare 100c.c. of agar. Reserve one-half of it for glycerine agar, and to the other half add 1 per cent. of glucose. Dissolve the powdered glucose in about 5c.c. of boiled, hot water before adding it to the liquid agar. After thoroughly mixing, distribute it in small sterile test-tubes. Sterilise, label, and store the same as ordinary agar.

Preparation of Glycerine Agar.—Take the balance of the agar prepared above and add 5 per cent. of pure glycerine. Thoroughly mix it with the liquid agar, after which distribute in tubes. Sterilise, label, and store as ordinary agar.

Preparation of Glucose Bouillon.—This is used in the fermentation-tube. Take 100c.c. of peptonised bouillon and add 1 gram of pure grape sugar (glucose). After it is dissolved and thoroughly disseminated through the bouillon by stirring or pouring, distribute the bouillon in the fermentation-tubes, filling completely the closed branch and the open bulb about half full. Sterilise it by discontinuous steaming for twenty minutes each day for three consecutive days.

Preparation of Lactose Bouillon.—This is prepared by adding 1 per cent. lactose to the peptonised bouillon. It is necessary, however, that the bouillon used does not contain muscle sugar. Bouillon free from muscle sugar can usually be obtained by macerating the meat for from 12 to 18 hours at a low temperature. After adding the lactose and thoroughly mixing it in the bouillon, sterilise, label, and store.

Saccharose Bouillon.—This is peptonised bouillon to which 1 per cent. saccharose has been added. It is prepared from bouillon free from muscle sugar, in the same manner as lactose bouillon.

THE LECORNU CELLULAR KITE.

THERE is no amusement more fascinating, more instructive, or more easily engaged in by everybody than kite-flying. Although it is much in favour on the other side of the Atlantic, it is yet too much neglected in France. Almost everywhere in the United States there are to be found kite clubs analogous to the French bicycle and photographic societies, and which are in the habit of organising competitions of various kinds. It is a great pity that the sport is not indulged in in France as much as it deserves to be, for the kite is a wonderful apparatus, of which a host of curious and interesting applications may be made. It is almost without a rival for the study of atmospheric electricity and for topographic photography. It may be employed as a life-saving and signalling apparatus, for the practice of wireless telegraphy, for the study of meteorology, and even, as with the balloon, for making ascensions. The ordinary kite is familiar to everyone. Whatever be its form, lozenge-shaped, rectangular, elliptical, hexagonal, octagonal, &c., it always consists of a plane surface provided with a bridle to which the string is attached, and with a tail of varying length. This last-named appendage was for a long time looked upon as indispensable, and it seemed as if a tailless kite could not be thought of; but the Oriental kites imported from China and Japan destroyed such an opinion.

If we attentively examine the tailless Japanese and Chinese kites we shall see that they are no longer plane, but either (like the Japanese flies) consist of a plane part and two wings forming pockets and inclined towards the rear, or (like the Chinese apparatus) present curved surfaces. This, in fact, is because the plane kite is unstable. It is like a plank that we should like to keep in equilibrium in a current of water, and at right angles therewith, in holding it by a single rope. It is evident that however carefully we fixed this rope at the centre of the thrust, the board would be in a state of unstable equilibrium, and would continually revolve around its point of attachment. It would be entirely different if we should fasten a string to the handle of an umbrella and present the concavity of the latter to the current. When we study the stability of the tailless kite, we are thus led to seek forms that are entirely different from those of the flat kite.

Without extending this brief statement of the question any further, we shall merely say that one of the best forms to adopt for the tailless kite is the cell. We mean by this the form obtained with at least three, but generally four, planes intersecting each other in pairs according to parallel straight lines. We thus obtain a sort of bottomless box. The walls are of paper or of some light fabric. To make the matter plain, let us conceive of a cell of square section. This will present itself in the form of a box, of which the four sides will exist, but of which the top and bottom will be suppressed. If we present this cell to the wind in such a way that two of the sides shall be horizontal and two others vertical, it is evident that the air will pass freely through the cell without exerting any pressure capable of raising it; but if we elevate the front edge of the cell slightly, the wind, in pressing the lower surfaces of the walls that were previously horizontal, will tend to raise the apparatus. The latter will have great stability by reason of the existence of the two vertical sides, which, in a manner, play the same part as the keel of a boat.

The sides of the cell that undergo a pressure are the sustaining planes, and the vertical sides the directing ones. If we place two of these cells one behind the other, in leaving between them an interval equal at least to their length, we shall have the Hargrave cellular hovering kite adopted at the Blue Hill Observatory (in the United States), where, through the intermedium of meteorological registering apparatus, it is used for exploring the upper regions of the atmosphere. In certain experiments such apparatus have reached heights of from 5,000ft. to 6,500ft.

If, on the contrary, we juxtapose not two, but a greater number of cells—say, six, eight, twelve, or more in the same frame—we shall obtain the multicellular hovering kite, which we have devised and constructed after numerous tentatives.

We at the outset placed four rectangular cells one above another, and thus obtained an apparatus having exactly the form of a set of shelves. We tried this upon the beach of Cobourg in 1898; but, since the stability did not prove as great as that which we desired to obtain, we were led to multiply the number of cells and to employ square cells, with one diagonal and horizontal and the other vertical.

Each cell taken isolatedly thus flies upon the side and presents to the wind surfaces that are inclined, one to the right and the other to the left, somewhat as in the case of a boat that is floating upon its keel.

We have in this way constructed a kite of wonderful stability, which rises with the greatest ease, and maintains itself in the air with complete immobility.

Our multicellular hovering kite is very easily constructed. It requires, as a rigid frame, only four wooden rods, having the length of one cell and placed at the four corners of the entire affair formed of all the cells, and two cross pieces, one in front and the other behind, to give rigidity to the whole.

It may be put together and taken apart in a few minutes with the greatest ease. After being taken apart, it may be rolled up and carried very easily upon a bicycle.

It is so easily managed that anyone can send it aloft and manœuvre it without difficulty. When it is in the air, it is so stable that ten yards of string may be suddenly paid out without causing it to fall. Finally, its sustaining power is so great that in a brisk wind we have been able to make it raise a dummy formed of a child's clothing and fixed to an umbrella. And yet the kite is not of very large size, its dimensions being 4ft. in length and breadth, and 16in. in depth, while its weight is little less than 4½lb. The *Scientific American* is indebted to *La Vie Scientifique* for the description of this form of kite. The figures represent the method of mounting the kite, the kite ready, and the method of raising.

BLACKSMITH'S STUDY OF CAST STEEL.*

THE most important element in steel, as far as the tool-user is concerned, is carbon. Cast steel is iron and combined carbon in the hardened state, and of iron and graphite carbon in the annealed state. Carbon in its combined state is akin to the diamond, and in its uncombined form is akin to black lead.

I might evolve a nice little theory by saying that the higher the percentage of carbon in the combined state, the closer it approaches the diamond, when we remember that two per cent. carbon is very high and is seldom used. The toolsmith should know the carbon points of steel he is working. For example, if he has been in the habit of making milling cutters out of steel containing 125 carbon points he knows just what degree of heat is suitable for the right temper. If he should, perchance, receive a piece of steel with only 110 carbon points, he would get the milling cutter too soft, yet he could in either case make a satisfactory tool if he knew the carbon points.

* Extracted from a paper read before the Northwest Railway Club by Mr. George F. Hinckens, master blacksmith St. P. and D. Ry.

Purchasing agents should bear this in mind, and give the mechanical department what they call for, for it is both common sense and true economy to leave such matters to the judgment of the mechanical department. Find out what carbon points are suitable for the purpose required, and if you will change, notify the mechanical department, or else you will confuse the temper, for he cannot discern the difference by inspection.

I will give you the carbon points as used in the St. Paul and Duluth Ry. shops with relation to the various purposes for which our tools are required. Remember a point in this case means one-hundredth of one per cent. of carbon—a very energetic element and a dominant factor indeed; hence a few words only are necessary to indicate the importance of carbon with its relation to steel.

One hundred and fifty carbon points, suitable for lathes, plantes, boring car-wheels, &c.; 135 carbon points, suitable for large lathe and planer tools, medium size dies, &c.; 125 carbon points, suitable for taps, reamers, and drills; 115 carbon points, suitable for screw-cutting dies, chisels, punches, and milling cutters; 105 carbon points, suitable for cold chisels, punches, dies, large taps, milling cutters, small shear knives; 95 carbon points, suitable for large punches, shear blades, large dies, and some blacksmith tools; 85 carbon points for stamping dies, hammers, cold sets, track chisels, and smith tools; 75 carbon points for swedges, flatters, cupping tools, and blacksmith tools generally. In ordering steel give the temper, or state the purpose for which the steel is to be used. Once in a while the steel worker will complain that the steel varies, and the results are not always the same; the trouble was that he got hold of the wrong bar, or got the bars mixed by mistake.

The carbon points given are obtained from average results, but must not be adhered to strictly, as conditions may necessitate a deviation. Take a chipping chisel containing 125 points, such as we use in the tool-room for fine and delicate work, and for comparison we will take a boiler-maker's chipping chisel containing 105 carbon points; now, here are conditions that cause a large variation, a difference of 20 carbon points in the two chisels. Again, as to planer and lathe tools possessing different values as to carbon. For example: a lathe tool for turning hard tires, tool steel, or for hard roll turning will require 150 carbon points, whereas a lathe tool for turning bolts or soft material will require from 125 to 135 carbon points. The speed of the machine and the nature of the material to be cut are factors in determining carbon points; so you see there are no hard and fast rules. I will also mention that carbon costs nothing, comparatively speaking. The difference in price between six-cent and thirteen-cent per pound steel is not due to the difference in carbon, but to material and skill. There are some difficulties in estimating exactly the value of carbon points, and it requires unusual attention, watchfulness, and thorough supervision on the part of the toolsmith and in the tool-room. There are many factors to be considered in estimating the results of all of the many uses to which steel is put, as well as the treatment of the article itself.

In heating steel, as in everything else, science and common sense should be exercised. It is very discouraging to the steel-maker to find that after all his care and expense his product is abused in heating after it leaves the mill. Unequal heating will produce an inequality of the particles, and will cause their displacement in one direction or another when the steel is subjected to the forging process. Thus the different or varying state of heat appears to be of greater moment than is usually taken into consideration. In working a piece of steel with uneven heat the particles are pushed out of their normal position, and no amount of annealing can altogether replace them. The particles of steel will arrange themselves only in obedience to natural laws.

Forging steel at a black heat will crush the particles or bring about rapid crystallisation. Some say that the word "crystallisation" is not applicable, so I will say, "enlarged the crystals." Steel should be in a plastic state during the process of forging, and the heat should be as even as it is possible to have it; the force of the blow should also penetrate the whole mass, so as to prevent the drawing of the exterior surface away from the core or centre. When the outside of the steel is worked more than the inside, the effect is telescopic, and the steel can only be rehabilitated by annealing, and then by no means will the temper be uniform. Hence, do not work steel at too low a heat lest you strain it. Do not work it at an uneven or irregular heat, or the particles will be as variegated as the frost lines on a window glass. Too high heating will make the steel brittle and destroy its cohesive properties. The secret of successful tool-smithing is proper heating, and I will say that proper heating commences from the molten state at the mill.

Overheating has this effect on steel, as a writer on the subject puts it: "It changes the particles of pure steel to crystal of oxidised carburet of iron, and by cooling in water little diamond points of combined carbon and steel are fixed, but fixed so loosely in this crystallised framework that holds them that it breaks down and they crumble out."

I will call your attention to the matter of judging steel in the merchant bar by its structure or size of grain, and ask you to remember that this comes under the head of heats. I have in mind a lot of crucible cast steel for springs which was rejected by the springmaker on account of its coarse texture. I knew that the steel was all right, but I could not convince him. So I wrote to the manufacturer about the coarse grain in his steel. I knew I would receive in reply a corroboration of my views in the matter, which are that this particular lot of steel was finished or had passed through the rolls as a final at a high heat, resulting in a very coarse texture. Had this same steel been reduced to a smaller size, which would have necessitated further rolling and a reduction in heat, the grain would have been finer in structure. Of course, this steel contained from 60 to 70 carbon points, and I think its structure was due more to temperature and the rolling than carbon.

Over-heating, under-heating, over-working, and under-working will change the structure of steel, that is, down to 40 carbon points and below, as we have fully demonstrated in our shops.

Every degree of heat in any of its stages registers itself in a piece of steel as correctly as a thermometer will register every degree of heat in the atmosphere. The higher steel is in carbon, the more mercurial; in other words, high carbon steel is more sensitive and yields to influence more readily than low carbon steel.

The proper heat is learned only from experience. If the toolsmith, in forcing a tool, were to reduce a piece of steel from 6in. to 3in. in diameter, he would use a higher heat than in reducing a piece a piece of steel from 2in. to 1½in. in diameter. In the first, or larger piece, he heats up to a coarse grain; but the sufficient amount of hammering in reduction of bulk refines the steel, and no harm is done. If the second or smaller piece is heated up to the same high heat as the first piece, you start with the same coarse grain as in the large piece, and a reduction of only ½in. diameter under the hammer is insufficient to hammer-refine the steel; besides, the larger piece will hammer-refine and reduce in heat at the same time. Not so with the smaller piece; it will receive no hammer-refining, and the high heat will leave its structure coarse.

In dressing a flat chipping chisel, the toolsmith will reduce or narrow-up the end slightly before the red leaves it, and on the final finish he will hammer on the flat side of the chisel until it becomes black, using judgment as to weight, number of blows, and condition of heat, remembering the "fatal blue." Now, this is the right heat for this particular tool, and the heat method for making the chisel compact. But beware lest you destroy the chisel with just one blow of the hammer, and with the same heat as when striking the flat side. One blow struck on the edge will rupture the chisel. You know that a book will stand considerable pressure when the force is applied to the flat surface; but the same pressure applied to the edge will distort every leaf in the book.

This also applies to side tools, thread tools, or tools where the transverse section is thin. But do not mistake this for a forging heat, for we are not forging in this case—only giving a final finish, or hammer-refining—packing the steel, as it were, and this procedure is limited to only a few cases, and cannot be universally practised. We know that the higher the degree of heat the more hammering or reduction in diameter the steel will stand. We also know that if we are to reduce the diameter of the piece only slightly, we should reduce the heat correspondingly, or we shall lose the desired compactness and fine grain. Of course, we can get a fine grain by annealing and hardening, but let us help that happy condition along throughout the whole course.

The restoration of the particles of steel to their normal state, that have been changed by forging, is brought about by annealing. Therefore, the answer to the question as to what degree of heat will cause the changes that will bring about uniformity in structure is, when the steel is uniformly hot throughout the mass, it should be removed from the fire at once. If left in any longer, it will become "soaked," and will not temper as it should.

The annealing due to slow cooling will remove in a great measure all undue strains that were put in the steel by hammer, sledge, or steam-hammer. Annealing allows the particles of steel to arrange themselves in their right condition, but we must remember that bad strains can only be imperfectly eliminated by annealing, and it should be the inflexible purpose of the toolsmith to guard against working strains into the steel while forging.

Steel that has been improperly worked, that is, that has had the grain crushed, cannot be rectified by annealing; there is a certain amount of brassness that no annealing can eliminate. The particles that, through bad or cold working, have become crushed, telescoped, and disintegrated will not come back.

The action of heat is closely related to the hardening process, and the value of the physical and carbon properties are certainly known to be dependent on the degree of heat in the steel article before immersion. The cohesion, adhesion, or whatever you may wish to call it, or the chemical affinity of carbon and iron, are without doubt influenced by too high or too low a heat.

In speaking of heat for hardening, we are governed by carbon points; the higher the carbon the lower must be the heat, which will register itself. When the tool is fractured, if it shows a sandy grain, it proves that the steel was overheated; if, on the other hand, the grain is fine and of clear appearance, it indicates a proper heat; if a variation in grain, it indicates uneven heating.

Cooling a piece of steel that is unevenly heated causes a complex arrangement of the particles—a separation in one place and a crowding in another—thus producing strains and water cracks. Hence it behoves the hardener to so regulate the heat on the article to be hardened that the whole mass will be uniformly heated. It should be as uniform in colour as possible. A piece of steel so heated, and immersed in water that is in motion, will give results that will gladden the hearts of all concerned. If the article to be hardened is bulky, the heat radiating from it will repel the water, and envelop the article in a film of steam surrounded by hot water, and as steam and hot water are poor conductors of heat, they will prevent rapid cooling. The more instantaneous the cooling, the more harmonious the particles, coupled with uniformity of good hardness.

One of the great difficulties about heating steel for hardening is that of determining the time when the whole mass is uniformly hot.

Mr. W. O. Johnson and myself experimented with two ⅝in. wornout taps. We laid both taps in the fire and brought them up to a hardening heat; we then withdrew one from the fire and plunged it in cold water. The other tap we held in the fire for about seven minutes; during this longer period we were very careful about keeping the heat in a fixed state, and also at the same temperature as the first tap. After the expiration of seven minutes we plunged it in cold water. On examination we found that the tap that received the short period of heat did not arrive at the refining heat, and consequently showed a very coarse grain, whereas the one that remained in the fire the longer period had attained the refining heat and showed, after breaking, a nice refined grain.

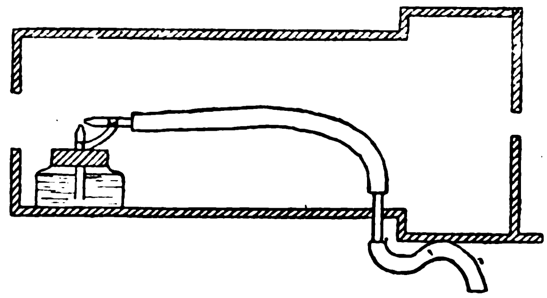
This experiment emphatically demonstrated that the relative difference between the coarse and fine grain was due to proper time exposure. The surface particles are heated first, and from the surface particles the heat is transmitted to the adjacent ones, and soon to the interior. The heat of the surface particles must lag or wait for the adjacent particles, and so on through the mass. When all the particles in the whole mass have arrived at a corresponding heat, the article should then be taken from the fire and immersed. If you ask me how I know when the mass arrives at the ideal heat, my answer is: I do not know. When in doubt, take the safer side, and keep the steel in the fire a little longer, as it is a question of judgment, and comparative at that.

Mr. F. Law, who perhaps has given the subject more study than any investigator that I know of, says that "the point of recalescence is indicated by prominent waves playing over the bar, when the wave disappears it disappears from the centre of the bar, which is an indication that the refining is completed, and the temperature of the bar is then uniform throughout, and if quenched under these conditions we obtain the ideal steel in the hardened state." The hope is justified that in the near future we shall learn to recognise that very exact point of recalescence, but for the time being the most of us will have to depend on the old methods.

AN X-RAY DELUSION.

THE following description of an X-ray delusion apparatus is by Gustave Michaud, D.Sc., in the *Scientific American*:—A Boston firm sells, under the name "X-Ray camera," an apparatus which apparently enables an object to be seen through any opaque substance. It is hardly necessary to say that the X-rays have nothing whatever to do with the phenomenon, which is really produced by a set of four hidden mirrors, that conduct the light round the opaque object. I have recently devised and constructed a little apparatus which is just as deceitful as the "X-Ray camera," but which is more readily made, and gives results far more astonishing for spectators who have not been told the secret of its construction. It apparently reproduces, instantaneously and neatly, the interior of the human body, giving to every organ its natural colour. The whole operation is performed under the eyes of the bewildered sitter, who watches the X-rays in what seems to be the act of drawing and painting, before his eyes, his vital organs.

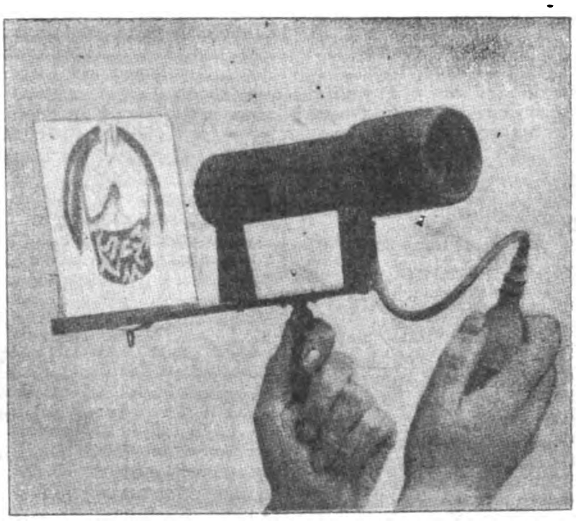
The apparatus looks like the objective tube of a camera, with the plate on which the image is to be



produced in full sight of everyone. The apparatus is placed opposite the person whose viscera are to be photographed, and to heighten the effect a lamp may be solemnly placed behind the sitter. The operator invites everyone to look at the white sheet of paper, and presses the rubber bulb of the shutter. A coloured image appears instantaneously on the paper. The lungs are of a bright red colour, the heart is darker, the veins are blue, the stomach and intestines are of a greenish tint; other parts of the body paint themselves in black on the white paper. This sudden apparition generally startles the sitter; but a few remarks on the healthy looks of his lungs will place him at his ease. The photograph is taken out of the apparatus and passed among the spectators.

Two distinct parts of the apparatus co-operate in the production of that X-ray trick—namely, the sheet of paper and the objective tube.

Before the experiment the sheet of paper is treated as follows:—It is pinned over any anatomical drawing showing the position of the principal thoracic and abdominal organs. If the sheet of paper is not too thick, the drawing can be seen through it. The space occupied by the lungs is then painted with a diluted solution of sulphocyanide of potassium. A more concentrated solution of the same salt is used to fill the space outlined by the heart and principal arteries. A few big veins are painted with a solution of ferrocyanide of potassium. A more diluted solution of the same salt is used for the stomach and a few intestinal folds. The rest of the body is uniformly painted



with a concentrated solution of tannin. The whole operation need not take more than five minutes. When the paper is dry the drawing is absolutely invisible, for all the above-named solutions are colourless. The sheet of paper is now ready for use in the apparatus.

The objective tube does not contain any lens, but merely a small atomiser filled with a solution of ferric chloride. When pressed the rubber bulb sends air, not as every spectator believes, into a pneumatic shutter, but into the atomiser. As a result a fine and invisible spray of the perchloride of iron solution reaches for a moment the sheet of paper. What follows is easily understood by every student of analytical chemistry.

The reactions between ferric salts on one side, sulphocyanide of potassium, ferrocyanide of potassium, and tannin on the other side, are among the most sensitive of analytical tests, owing to the extraordinary intensity of the red, blue, and black colours which originate in these reactions. Hence the instantaneous production of the coloured picture.

The illustrations show the objective tube in section, and the apparatus complete.

In Tasmania there are 437¾ miles of railways open, and the train mileage last year was 761,309.

NOTES ON OZOTYPE.

At a recent meeting of the Leeds Camera Club, a lecture was given by Mr. Thos. Manly, on "Ozotype," of which he is the discoverer. Ozotype is an important development in carbon printing, the essential difference being that in this process there is a visible image, while in the ordinary form of carbon working there is none. The image is printed on the transfer paper, and the tissue is then brought into contact with it. The print is formed by the chemical action of certain salts with which the transfer is coated. This solution is protected by letters patent, and will be shortly on the market. Any pure paper may be used, and is evenly coated with the sensitising solution, and dried in the dark. It will keep well for a month or six weeks if kept dry. It is placed under the negative in the ordinary way, and the image is clearly and distinctly visible of a brown colour, and printing is stopped when faint detail in the high lights is visible. The image is much more distinct than it is in platinotype. The print is then well washed, and in this state can be put aside for an unlimited time, and subsequent operations conducted at leisure. A piece of ordinary carbon tissue, insensitive, is now placed in an acetic solution of water 40oz., glacial acetic acid 30 minims, hydroquinone 30 grains, glycerine 1 drachm, and allowed to remain about a minute. The print is now plunged under the surface of the solution, brought into contact with the carbon tissue, and quickly withdrawn. Squeeze the two surfaces together, and allow to dry. It is then developed as a carbon print, giving a correct image, while the ordinary single carbon transfer gives a reversed image. The subsequent print is in every respect equal to any carbon print, with the advantage of possessing greater softness of outline and perfect half-tones. The prints may be coloured instead of being pigmented with the carbon tissue by using a colourless salt of aniline, strongly acidulated with sulphuric acid, pleasing and brilliant colours obtained, and, with subsequent treatment by ammonia and other oxidising agents, different colours produced at will.

CASTING ALUMINIUM ALLOYS.

Several United States patents have recently been granted to Mr. William A. McAdams, Borough of Brooklyn, City of New York, for a method of casting aluminium alloys, the essential feature of which is the rapid removal of the heat from the molten mass after pouring. From the specification of a patent relating to the casting of aluminium alloys composed of aluminium, zinc, and copper, with or without a small percentage of nickel, in which the metal aluminium predominates, the following interesting information is taken:—Aluminium when melted cools slowly, so slowly that other metals which are present in molten state in the molten aluminium are permitted to segregate and form large crystals before the slowly-cooling aluminium checks to any considerable degree their segregation and crystallisation, thereby materially reducing the strength of the casting. Furthermore, the zinc and copper, because of their greater specific gravity, have a tendency to fall towards the bottom of the molten mass, and thus render the casting non-homogeneous.

The object of my present invention is to prevent such segregation, crystallisation, and stratification of the mixture during the process of the cooling, and thereby to add material strength to the casting.

In an alloy composed of 72 per cent. aluminium, 24 per cent. zinc, and 4 per cent. copper, or similar alloys in which the aluminium forms a greater part of the alloy, the hereinbefore described segregation, crystallisation, and stratification of the commingled metals will be liable to take place unless the molten mass is cooled so rapidly after pouring as to check the segregation and stratification before it can have proceeded to any great extent. By means of numerous experiments I have found that the cooling should take place rapidly within certain well-defined practical limits, and that the heat should be taken from the molten mass at as nearly a uniform rate as possible. This may be accomplished where the casting is thin or small by using a metal mould of sufficient thickness to quickly remove the heat from the casting, and when the casting is to be thick or large the mould may be surrounded by a cooling medium to assist it in removing the heat with the required speed and uniformity.

To carry out my process successfully, the heat should be removed from the casting as rapidly as at the rate of one-fifth of a calorie per second, and, on the other hand, it should not be removed more rapidly than at the rate of two calories per second, as when removed more rapidly than this rate the sudden chill is found to produce the same weak structure that is produced when the heat is removed at a rate less than one-fifth of a calorie per second. The best results are obtained by removing the heat at the rate of from one to one and one-tenth calories per second—a rate much more rapid than is common in the ordinary use of metallic moulds. I found that this treatment of aluminium alloys, in which the aluminium forms the greater part of the alloy, will increase the strength of the casting from 80 to 100 per cent.

I have found by careful experiment that a bar composed of aluminium, zinc, and copper, combined in substantially the proportions hereinabove mentioned—viz., 72 per cent. aluminium, 24 per cent. zinc, and 4 per cent. copper—·968sq.in. area in cross section, cast by the process hereinabove set forth, supported upon inverted V edges 12in. apart and with the weight applied by a V edge midway of its point of support, showed a transverse stress of 32,000lb., with a deflection of ·21in. under a load of 3,200lb., the same bar showing a tensile strength of 39,000lb. A 2in. length of the bar standing on end supported a load of 70,000lb. without visible deformation, and actually sustained 98,000lb. before breaking with a shearing crack. I have further found by careful experiment that a similar bar of metal, composed of the same material and in the same proportions, cast in the ordinary manner, and allowed to cool at a rate not greater than one-fifth of a calorie per second, showed a transverse stress, under the same conditions as before, of only 2,050lb., a deflection of ·13in. under a load of 1,900lb., and a tensile strength of 22,000lb.

Can Ants Hear?—Whether ants can hear is a question which has for some time been engaging the attention of Mr. Weld, of the Iowa University, who has published an account of some of his experiments, and the conclusions he draws from the same in *Science* of Nov. 24. He states that for many years it has been the accepted opinion amongst naturalists that these insects are not endowed with an acoustic sense, at least within the range of sounds perceptible to the human ear. This opinion is based upon the failure of experiments to show that even the loudest and shrillest noises produce the slightest effects on ants subjected to their influence. This, however, is not the result of Mr. Weld's experiments upon several American species of these insects. In one case an ant confined in a test-tube was brought near a milled disc rotating in the air. At each sound from this apparatus the ant showed unmistakable signs of agitation, quickly moving its head and antennæ. Again, when shrill sounds were produced close to a colony protected under glass, the ants instantly showed by their rapid movements signs of excitement and alarm. This leads the experimenter to conclude that at least some (and possibly only American) species of ants are capable of perceiving vibrations, conducted though the air or other media, which are audible as sound to the human ear. He is, however, careful to add that this does not necessarily demonstrate that they hear in the strict sense of the word, but merely that they are capable of perceiving ordinary sound vibrations.

SCIENTIFIC SOCIETIES.

ROYAL METEOROLOGICAL SOCIETY.

THE monthly meeting of this society was held on Wednesday evening, the 20th inst., at the Institution of Civil Engineers, Mr. F. C. Bayard, LL.M., President, in the chair.

Mr. Baldwin Latham, M.Inst.C.E., read a paper on "The Climatic Conditions Necessary for the Propagation and Spread of Plague." The bubonic plague is primarily due to a specific organism or microbe of infinitesimal size—so small that probably 250 millions of them would be required to cover a square inch of surface. Plague is infectious and contagious, and is greatly influenced by pestilential emanations from polluted and waterlogged soils. The author gives accounts of various outbreaks of plague in this and other countries, including the Great Plague of London in 1665, when 7,165 deaths were recorded in one week in September. Plague is undoubtedly a disease of the poor, and attacks most readily those living on a low diet. The conditions which are conducive to the spread of plague are identical with those which give rise to the escape of malaria from the ground. That the ground itself exercises an enormous influence upon plague is shown by the fact that in all the epidemics, persons living on the ground floors suffer to a much greater extent than those who live in the higher stories of the houses. Mr. Latham says that there cannot be a doubt that the conditions which ordinarily produce evaporation from water or land surfaces are identical with those which produce exhalations from the ground; and these exhalations consist largely of vapour of water carrying matters injurious to health with them. Mr. Latham has discussed the meteorological observations (including the temperature of the soil at the depth of 9in., 20in., 60in., and 132in.) made at the Colaba Observatory, Bombay, and has compared them with the number of deaths from plague during the recent epidemics in Bombay. He says that if the temperature of the air increases beyond the temperatures of the ground so that its dew-point is above the temperature of the ground, condensation takes place instead of evaporation. To this increased high temperature may be due the sudden stoppage of plague after a certain high temperature has been reached, which, by raising the temperature of the dew-point, stops all exhalation from the ground, and may cause condensation to take place instead of evaporation. So, also, a sudden fall of temperature causes plague to arise; for a fall of temperature means that the temperature of the dew-point must fall, and the tensional difference between a low dew-point and a high-ground temperature would at once lead to exhalations escaping in large quantities from the ground, and so lead to the liberation of the plague bacillus from the ground, accompanied with the exhalations necessary for its development.

Dr. R. H. Scott, F.R S., communicated a note on a remarkable dust haze which was experienced at Teneriffe, Canary Islands, on February 16 to 19, 1898. The haze during the period was exceptionally dense—so much so that a steamer was two days and three nights on a voyage from Teneriffe to Las Palmas, a distance she usually covered in five hours; while the *Tintagel Castle*, of the Donald Currie Line, was delayed for thirty hours, and the *Roslin Castle*, homeward bound, had the dust so thick that for 900 miles the sun and stars were obscured, and the ship was delayed two days.

THE total quantity of iron ore raised last year was 70,000,000 tons, which would give 36,507,500 tons of pig iron. This quantity of iron, it is estimated, would form a belt round the earth at the equator 2ft. wide and 7½in. thick.

AN American firm claims to have made the largest glow-lamp. It is of 5,000c.p., and has been constructed for use in a lighthouse. The lamp is of the two-filament type, the filaments being in parallel and taking 236 volts; the power taken is about 3 watts candle-power, the total power being therefore about 15 kilowatts.

Most Powerful Locomotive. — The most powerful locomotive in the world is in America, and has, it is stated, a total weight of 232,000lb., or about 103 tons. The total wheelbase of the engine is 26ft. 6in., of which 15ft. 9in. is the driving wheelbase. The total wheelbase of engine and tender is 55ft. 2½in., and the total length over engine and tender 65ft. 7¾in. The centre of the boiler is 9ft. 8in. above the rails. The height of the funnel above the rails is 15ft. 5in. This engine was built at the Brooks Locomotive Works, in America, and will run on the Cairo Division of the Illinois Central Railroad between Carbondale and Fulton. The steam pressure is 210lb. per square inch, and is generated by 3,500sq.ft. of heating surface. The steam is used in two cylinders, each 23in. in diam. by 30in. stroke. The cylinders drive four coupled axles, on which are wheels 57in. in diam. The tender has a capacity of 7,000gal. of water and 12 tons of coal.

SCIENTIFIC NEWS.

BY means of a radiometer devised by Mr. E. F. Nichols, of Dartmouth College, the heat radiation of the stars has been tested at Yerkes Observatory. The radiometer consists of two discs of mica, each of 2mm. diameter, blackened on the face, and supported by a light cross arm on each side of a thin glass-stuff staff hung by a fine quartz thread in partial vacuum. The rays of light reach the radiometer through a window "glazed" with fluorite, and collected by a silvered-glass mirror of 24in. aperture.

It is stated that the University of France has, by special decree, recently been authorised to accept a magnificent gift from M. Raphael Bischoffsheim, the well-known member of the Institute and Deputy, who has presented it with the freehold of the Nice Observatory. M. Bischoffsheim founded this observatory many years ago, and in giving it to the University he includes the adjoining land near Mont Gros, the whole of its contents, which comprise instruments of great value, and a library of over six thousand volumes, together with the branch observatories at Mont Moumer and Mont Macaron. In addition, the donor has handed over a sum of two and a half millions of francs, the interest of which is to be devoted to the maintenance of the observatory after his death. The *Figaro* estimates the total value of this handsome gift at five millions of francs.

The *Journal* of the British Astronomical Society (Dec. 19) contains several reports of branches, the report on the meteoric section, several interesting papers, some correspondence, and, besides the usual notes, a biographical notice, with portrait, of a distinguished ex-president, Nathaniel E. Green, F.R.A.S. The report of the section for the observation of Jupiter has also been issued in the *Memoirs*.

With reference to the small planet discovered by Mr. Coddington, of the Lick Observatory, mentioned on p. 404, Herr Kreutz, of Kiel, thinks there is no doubt that it is identical with one discovered by Dr. Palisa in 1896. The ephemeris is given as R.A. Jan. 1, 1900, 1h. 10m., S. Dec. 3° 1·5'.

The *Astronomische Nachrichten* will, with the beginning of the new year, be confined to the recording of general observations, and a separate paper (presumably a sort of supplement) will be issued giving the ephemerides of comets, planets, &c. The address of the office for publication is Niemannsweg 103, Kiel.

The parallax of the sun is, according to M. Bouquet de la Grye, 8·80" ± ·01. The calculations from the photographic measures of the transit of Venus are not completed, but the figures given are probably as near the actual result as the revision will work out.

A "note" that may be useful appears in a memoir presented to the Paris Academy of Sciences by M. Janssen on the work done on Mont Blanc during 1899. It is found in the statement that naked galvanised iron wires were quite serviceable for telegraphic purposes between the observatory and distances up to 1,700 mètres, the wire lying uncovered on the glacier ice without making "earth" in the telegraphist's sense.

The total amount subscribed for a statue to Lavoisier is stated to be 98,000 francs (£3,920), and M. Barrias has been instructed to execute the statue and the bas-reliefs for the pedestal. The site granted for the statue is an open space behind the Madeleine, and an opportunity will be taken to unveil the statue probably in July—at all events while the Exhibition is open.

It is announced from Hobart, Tasmania, that Mr. James Backhouse Walker, F.R.G.S., died there last month at the age of fifty-eight. He was the eldest son of George Washington Walker, who, in conjunction with James Backhouse, between the years 1831 and 1840, carried out the well-known Friends' Mission to Australia, which had no small influence in reforming our convict system. Mr. Walker was widely known for his keen interest in all public work tending to promote the well-being of the colony, although he took no part in political life. As Vice-Principal of the University of Tasmania, he had an active share in advancing higher education, and he devoted much time to philanthropic objects, and especially to promoting the welfare of the working-classes by means of schools, clubs, and other societies. For many years his house was a literary and intellectual centre for visitors to Tasmania.

Before the Departmental Committee on Preservatives and Colouring Matters in Food, Mr. T. Bond, consulting surgeon to Westminster Hospital, states that he had given boracic acid, which was largely used for preservative purposes, internally, for many years, in doses of ten grains, chiefly in bladder diseases, as an antiseptic, and had never found any ill-effects, even following its administration for many weeks. His usual dose was ten grains three times a day. It did not seem dangerous to him that a drug prescribed by a doctor should be liable to be taken by the patient from other sources in uncertain quantities. Even in the case of children he did not think there would be any risk. Asked whether the public would be justified in insisting that the presence of that drug should be notified in all articles preserved by it, he said, I think that would be a proper thing to do. At the same time, I believe it to be an absolutely innocuous preservative. If a child of one or two years of age took 15 or perhaps 20 grains a day—a quantity it might get in four pints of milk—that would be more than he would like to give the child, but he knew of no harm that would result. Asked if he would advocate that if preservatives are used the nature and amount should be stated, he said, I think that would be an excellent thing to do. With regard to salicylic acid, he had given it in the same doses as boracic acid and had never seen the slightest ill-effects from it. If used as a preservative, its presence and quantity should be stated. Two grains in a pound of jam—sufficient to preserve it—would do less harm than the pound of jam. Ten grains each in a quart-bottle of wine, cider, or beer would be safe; and if a man drank a bottle of each the 30 grains of salicylic acid would do him less harm than the alcohol. He was distinctly of opinion that the presence and quantity of preservatives, generally, should be stated.

The committee on colouring matters in food and preservatives appear to be receiving some remarkable evidence. Prof. A. Wynter Blyth said that the so-called tar colours were used nowadays, but he is reported as stating that none of the aniline dyes would be injurious to health if used in the usual quantities. The question as to whether the copper used with "green" peas is injurious has been the subject of examination for many experts, but it appears that they do not condemn it—though it seems absurd to use a chemical to colour a vegetable, merely for the sake of pleasing the eye. Borax, boracic acid, salicylic acid, &c., have been under review; but whether harmless or not there is a general opinion that articles treated by any of them should be "labelled."

The Manchester Literary and Philosophical Society have awarded the Wilde Medal for 1900 to Lord Rayleigh for his work in connection with experimental and mathematical physics and chemistry, and Lord Rayleigh will deliver the Wilde Lecture in February. The Dalton Medal is awarded to Sir H. E. Roscoe, and the Wilde Premium to Prof. A. W. Flux for the papers on economic questions presented to the society.

It is announced that Prof. Freeman, of the Armour Institute, Chicago, has been experimenting on the continuous production of calcium carbide. He uses a powder composed of 6 parts lime to 4 parts coke, and feeds the powder through a hollow carbon electrode into the electric furnace, with the result that a continuous supply of "molten carbide" is obtained. It has not yet been determined whether the process can be worked commercially with economy, the object, of course, being the production of acetylene at a low cost.

At a meeting of the Royal Photographic Society, Capt. W. de W. Abney, C.B., R.E., F.R.S., read a paper on a "Sensitometer for Three-Colour Work," which consists of a disc with arcs of suitable colours, the bands being so proportioned that when the disc was rotated the luminosity of each coloured arc would be the same; to take a photograph of such a rotating disc it would be necessary to use a screen which would cut off such quantities of light from each sector as would make the densities of each ring the same. If one colour was too dense when a certain screen was used, the experimentalist must remember that its complementary colour must be added, or possibly a mixture of two complementary colours

where the rings were each of varying density. The luminosity of the colours of the several sectors, taken in the electric arc light, were given as follows:—White 120, yellow 70, red 45, green 32, blue 16 8, violet 12·2, black 2. Photographs were shown of the rotating parti-coloured disc, taken on Cadett's spectrum plate and with the Cadett screen, the densities of the different colour bands being identical. The application of the method to the production of the negatives for three-colour work was very fully dealt with, tables and diagrams being given for the facilitation of the production of the necessary screens; the details are of such a nature that they cannot possibly be condensed into summary form, but they will, in due course, be published in the Society's journal.

The largest express engines ever built are, it is said, now in use on the Lake Shore and Michigan Southern Railway. They are capable of hauling trains of 500 tons, exclusive of engine and tender weight, at speeds of over 50 miles per hour. The engines are six-coupled, with a four-wheel bogie, and have cylinders 22in. by 28in., and driving-wheels of 6ft. 8in. diameter. It is stated that one of these engines, with a total load of 580 tons (English), in spite of a heavy side wind, made the run of 183 miles from Buffalo to Cleveland in 3h. 26m., of which 16m. were occupied by stops for water at three intermediate stations. That gives a speed of 58 miles per hour for the entire run, while seven miles were made at 83¾ miles per hour, and 41 miles at 65 miles per hour. The train consisted of two sleeping-cars, five post-office cars—on six-wheeled bogies—and two ordinary coaches.

The "feeders" (that is, cables for conducting electricity) to the new North-Western Electric Elevated Railroad in Chicago are to be of aluminium, which is said to be cheaper than copper, although the conductivity is less. Weight for weight, however, the aluminium is stated to convey more current, and aluminium cables are coming into extensive use in America. The question of economy depends mainly on the durability of the aluminium as compared with copper.

The following statement requires some little corroboration before it can be accepted as truth:—"An interesting curiosity in ethnology has been reported to the United States War Office. Some Creek Indians (American), employed among the troops in the Philippines, discovered a tribe of Malays in the southern part of the island—negroes—whose dialect was identical with their own. The Creek Indians were able to act as interpreters without any difficulty." If true, the fact will then be most interesting and worth much investigation.

An illuminated address, his portrait, and a sum of money were presented last week to Prof. T. Wiltshire, who has been for many years the secretary of the Ray and the Palæontographical Societies. Sir J. Lubbock made the presentation in the rooms of the Geological Society.

The Berlin Academy of Sciences will celebrate its 200th anniversary of its foundation on March 19—20, 1900.

THE Norddeutscher Lloyd steamship *Kaiser Wilhelm der Grosse*, the fastest liner in the world, has again broken her own record, having made the run from Cherbourg to Sandy Hook in five days sixteen hours.

THE total length of the railways in the colony of Queensland in June last was 2,745 miles, an increase of 110 miles during the past year. The train mileage has increased in the same period from 5,007,370 to 5,822,230.

THE metal used in the casting of bells is an alloy of copper, in the proportion of four parts of copper to one of tin. The copper is first melted and the tin added just before pouring. One of the secrets in bell-founding is to have the molten alloy heated to the critical point exactly.

THE new shops of the Erie Railroad Company in Jersey City are driven by gas-engines using producer gas. The producers are of the Taylor pattern, using rice coal—the smallest and cheapest size of anthracite—and the plant is a simple and compact one, taking up much less space, and requiring far less labour and attention, than would steam boilers furnishing the same power. The working of the plant thus far has been entirely satisfactory, and the records show a consumption of only 1·1lb. of the rice coal per horse-power hour, while the average duty of the engines is equal to 22 per cent. of the theoretical efficiency of the fuel consumed.

LETTERS TO THE EDITOR.

[*We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.*]

All communications should be addressed to the EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

*** *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks; a vice from whence great inconveniences derive their original."—*Montaigne's Essays.*

[43145.]—IT is a matter of common knowledge that the late Prof. Huxley was Dean of "the Royal College of Science" at South Kensington. Distinguished alike for his brilliant scientific attainments and for his fearless independence of character, it can scarcely fail to be a matter of interest to learn what his opinion was of those with whom he was associated in that charming little nest of rank jobbery, and this we are enabled to do from the utterance of the vice-president of the Committee of Council on Education at the dinner given to Sir John Donnelly on his retirement from the directorate. In proposing the health of the guest of the evening, Sir John Gorst, quoting from a letter from Sir E. Poynter, told how Huxley said: "To have a man like Donnelly in this place *keeps it sweet.*" What the scene of such barefaced and impudent self-advertising, jobbing, puffery, and log-rolling would have degenerated into without the restraining influence of the eminent man who has recently retired may be read between the lines of Prof. Huxley's dictum. Most happily for the nation, and for the dignity and purity of science generally, Sir John Donnelly is succeeded by as honourable and high-minded an English gentleman as himself. I mean, of course, Capt. Abney, who may be most thoroughly trusted not to connive at the low arts and wiles of some of those whom he has been appointed to supervise. But the whole thing is specially instructive as showing Huxley's opinion of (at all events, some of) his colleagues.

The *Astronomical Journal* for Nov. 13 (which I have only just seen) contains an elaborate series of measures of the fifth satellite of Jupiter made by Prof. E. E. Barnard with the 40in. refractor of the Yerkes Observatory. Among the most interesting results may be mentioned that it has been found that the motion of the line of apsides actually amounts to + 2·465° per diem, or something like 900° in a year, and that the period of revolution of the satellite = 11h. 57m. 22·647s., which Mr. Barnard alleges to be "doubtless correct to the $\frac{1}{100}$ part of a second." The distances of the satellite at the time of its greatest eastern elongation this year appear to have been—April 25th 48·34″, May 1st 48·29″, May 23rd 48·31″, and June 16th 48·03″, in each case at the assumed distance of Jupiter from the sun of 5·20. All the measures were made by viewing the planet through a plate of smoked mica, as otherwise irradiation must have seriously affected their accuracy, even if the brightness of the planet had not in addition rendered even the visibility of the satellite doubtful. Incidentally, Prof. Barnard compares the relative accuracy of measurements made with the filar micrometer and with the heliometer, expressing a very definite opinion in favour of the first form of instrument.

I was highly amused to see it announced in a morning paper, under the heading of "Berlin, Dec. 14," that "the Federal Council decided at its sitting to-day that the new century shall be reckoned from January 1, 1900." This, being interpreted, presumably means that the Berlin Federal Council will so reckon it; because, as regards the mere objective fact, it has as much, or as little power to decree that so fallacious a mode of reckoning shall operate as it has to prescribe that the planet Saturn shall revolve round the sun in 782 days 4h. 5m. 2·3064s., or that, for the future, the horns of the new moon shall point to the west. When will people realise that there never was a year 0? The year before our Lord's birth was 1 B.C., and the year of his birth 1 A.D. Until 1900 years (of which the first was 1 A.D.) are actually *completed*, we cannot possibly enter upon the 20th century.

Perhaps Mr. Lattey, the author of the article "Through a Small Telescope," on p. 394, will forgive me if I point out a misleading statement in (*a*) of his third paragraph, where he says, or is made to say, that celestial bodies are located "by their celestial latitude and longitude, termed in astronomy Right Ascension and Declination." Now, celestial latitude and longitude are the distance of a star not exceeding 90° from the *Ecliptic* north or south, and its distance measured *along* the same great circle from the First Point of Aries or Spring Equinox; while Right Ascension is its angular distance measured from the First Point of Aries eastward along the *Equator* (generally in time instead of in arc), and Declination is its distance (not exceeding 90°) north or south of the Equator. I mention this because a beginner finding in an astronomical work anything about Celestial Latitude and Longitude might well become hopelessly confused on reading the sentence which I have quoted above. What Mr. Lattey pretty obviously really meant to say was that Right Ascension and Declination in the Heavens were the equivalents of Longitude and Latitude *on the earth.*

We are certainly entitled to look for remarkable results from the very long-focussed photographic telescope of the Harvard College Observatory, to which reference is made in the first paragraph of your "Scientific News" on p. 404. Why, the image of the Sun in its primary focus will be upwards of 11in. in diameter.

To "A. B. M." (letter 43108, p. 405), who tells us that he will be glad to know what I have to say concerning Prof. Angot's "argument," I would simply reply that the entire extract which your correspondent gives seems to me strongly suggestive of the first two lines of the late Mr. Lear's well-known poem in "The Book of Nonsense":

"There was an old man of the Hague,
Whose ideas were uncommonly vague."

At the same time I am entirely in accord with the learned Frenchman in his expression of belief that "these studies are still too recent and too little developed to have already given results which may be considered sufficiently conclusive and general." *If* the position of the moon in declination has a definite effect on the general distribution of pressure on the surface of the globe, then (approximately) similar weather ought to occur every time she has, let us say, 22° of South Declination. But has the very cleverest of the statistic-dodgers and smoothed-curve manipulators ever yet succeeded in showing anything approaching to a weather-cycle?

And this brings me to letter 43109, on p. 406; in connection with which it is only necessary to remark that, if the *tidal* effect of the moon influences the weather, then ought there to be a semi-diurnal change in it everywhere. Is there?

In reply to "Student" (query 97237, p. 411), the ordinary Jewish year consists of 12 (approximately) lunar months, Nizan 30 days, Yar 29 days, Sivan 30 days, Thamuz 29 days, Ab 30 days, Elul 29 or 30 days, Tisri 30 days, Hesvan 29 or 30 days, Kislev 29 or 30 days, Tebet 29 days, Sebat 30 days, Adar 29 days; and in the so-called "embolismic" years, an intercalary month Veadar 29 days. It will be seen that, at the maximum, these regular months only amounted to 354 days, and the intercalary one Veadar was added on the 3rd, 6th, 8th, 11th, 14th, 17th, and 19th years of the Metonic cycle, so as to cause the coincidence of the festival of the Passover (which commenced on the 15th of Nizan) with the season when barley was ripe, because a sheaf of barley had to be offered with the Paschal lamb. Hence my querist will see that the connection of the actual lunar phase with the beginning of any month was of the most remote character. Proceeding to his next question, it would, of course, be possible by the aid of a most operose calculation to compute the day and hour of the New Moon on the 1st Nizan, A.D. 31. But Cui bono? It is very doubtful, indeed, if we know anything with the smallest approach to accuracy of the dates of Our Lord's birth and execution. Good Friday and Christmas Day are absolutely arbitrarily fixed, and there is not the smallest reason to suppose that they are in any legitimate sense anniversaries. As far as *historical* accuracy is concerned, the second Gospel is, I should think, immeasurably superior to the fourth. The first was probably expanded from it, and the third is admittedly a mere compilation from hearsay.

What in the world does "South Africa" (query 97252, p. 411) want to cement the lenses of his object-glass together if it defines properly with them uncemented? If they are properly adapted for the correction of spherical and chromatic aberration, the introduction of a medium of different refractive power between them might well derange their adjustment. It does, though, look a little as if your correspondent had had an inferior objective substituted for the original one.

The three stars to which "Orion" refers in query 97265 on p. 411, are, beginning with the left-hand one, ζ, ε, and δ Orionis. Now taking them in their order of Right Ascension, δ Orionis is situated in R A. 5h. 26m. 56s. and Declination 0° 22′ 26″ South; ε Orionis in R A. 5h. 31m. 11s. and Declination 1° 16′ 0″ South; and ζ Orionis in 5h. 35m. 43s. of Right Ascension and 1° 59′ 43″ South Declination. My querist does not say for what purpose he needs a book on the stars. If he wishes to obtain a good naked-eye acquaintance with the stars, Klein's Star Atlas, published by the S P.C.K., will be found useful, or if he wants a list of objects suitable and interesting for observation with the telescope, and can pick up a copy of Clark and Sadler's "Star Guide," published some years ago by Macmillan, he will find it very useful. I fancy that Proctor wrote a little book, too, called "Half Hours with the Stars," or some such title, but I have never seen it.

The query propounded by "W. A." (in letter 43121) on p. 425: "What has the above theory to say upon the subject?" strongly reminds me of the Frenchman, who, on being told that the facts were utterly against his hypothesis, retorted: "Tant pis pour les faits!"

In reply to the concluding paragraph of letter 43127, on p. 426, "E. P." must see that when it is 10h. 2m. 10s. p.m. at Maidstone, if we assume Maidstone to be 2m. 10s. East of Greenwich, it can only be 10 p.m. at the latter station, because the earth will have that piece more to turn on her axis ere the Greenwich Meridian comes under the star which is *on* that of Maidstone at the supposed instant. My querist is therefore perfectly right in his assumption that if Sirius souths at Maidstone on a given night at 10h. 2m. 10s. p.m., by a clock showing accurate *Greenwich Mean Time*, then, at that instant, the time *at Greenwich* is, as he supposes, precisely 10 p.m.

Mr. Monck (letter 43128, p. 426) is quite right in his assumption that Chambers was my authority for the conjunction of the four planets. I do not possess Mr. Williams's book. It is hardly necessary to add that I have not made the slight st attempt to check the calculations. I am very much too busy a man for that. Whether the conjunction happened B C. 2446, 2449, or 2441 is quite immaterial to my argument, which was simply that if Ussher is to be accepted as an authority the observation must ante-date the Deluge in B.C. 2349. Mr. Garbett cannot be allowed to dodge about and pick and choose among Ussher's dates, accepting them when they appear to support his crazes, and rejecting them when they oppose them.

The idea of Mr. Schucht propounded in letter 43139, on p. 428, rests upon the assumption that the ether is *matter*—which, in any sense that we can conceive, it most certainly is *not*.

I really could not help smiling when I read in letter 43144, p. 429, that Mr. Bywater's family had "kept secret" what used to be a most familiar thing among schoolboys. Why sheets of these "shadows," as they were then called, used to be purchasable at the shops where toy stages and plays were sold, thirty or forty years ago, and, for aught I know, much more recently still. Some of them were almost works of art, and demanded a considerable amount of care in cutting out. If I knew where to lay hands upon them, I am fairly sure that I still possess, somewhere, a number of them. Certainly I have, or had, one of the head of Our Lord much finer and more artistic than that of which your correspondent gives a facsimile.

M. Richards (query 97293. p. 432) will find Stebbing's "Navigation and Nautical Astronomy," published by Macmillan and Co., very good indeed. It contains, at least, one worked-out example of every rule given, and very often several.

In answer to query 97297 (p. 432), there can be no reasonable doubt that Sir William Herschel was mistaken in his assumption that the three bright points he observed on the dark part of the moon were active volcanos. Such lights may often be seen, and are referable to mountain peaks whose unusual power of reflection renders them perceptible by earthshine. "Dalphinus" may thus see Aristarchus for himself with the greatest ease, when the *lumière cendrée* renders the whole of the unenlightened part of the lunar disc visible soon after New Moon. A small telescope will exhibit this perfectly.

A Fellow of the Royal Astronomical Society.

THE PARTIAL LUNAR ECLIPSE OF DECEMBER 16, 1899.

[43146.]—THE day itself gave little promise of a fine evening, generally overcast conditions prevailing, and although there was a brief space between six and seven o'clock, when the moon shone brilliantly, as the night wore on thick clouds gathered most ominously, and by ten o'clock there was not the slightest probability of being able even to glimpse the eclipse. At 10.30 it was obvious that no observation could be attempted of the first contact with the penumbra, for the moon's place in the skies could not be identified by the eye, and at eleven o'clock several friends who had meant to watch the earlier stages at least, retired from the scene. Past experiences have taught me, however, never to abandon hope, and to be prepared, under even unfavourable conditions for observation. At 11.15 hope revived, for the moon showed itself through the clouds, and by 11.30 it was fairly well seen. There was then a perceptible darkening of the north-east limb, and at 11.40 it seemed to the naked eye as if the actual contact with the shadow had taken place. For my own part I found it quite impossible to note the exact moment of contact, even in the telescope, owing to the diffuse character of the edge of the shadow; but I would certainly say that it was on the limb at 11·45.

I had provided myself, as last year, with about a dozen outline maps of our satellite, and on these, which were placed by my side under the light of a bull's-eye lantern, I marked from time to time the progress of the eclipse, and jotted down the more striking features. The following are the notes I made:—

11h. 48m. Shadow very diffuse, and dirty-looking.

11h. 49m. Shadow's edge centrally through Grimaldi and on the west side of Aristarchus.

12h. 0m. Edge of shadow skirting east side of Copernicus, and slightly to the west of Sinus Iridum.

12h. 5m. Eclipsed portion almost entirely blotted out; no features discernible.

12h. 11m. Clouds thinning considerably; sky clear towards the north; eclipsed portion decidedly brightening.

12h. 14m. Edge of shadow a little north of Schickard, passing along the east side of the Mare Serenitatis, and just touching the east of Aristoteles.

12h. 20m. Edge of shadow bisecting Schickard and crossing the Mare Serenitatis.

12h. 23m. Edge of shadow west of Ptolemaus and west of Posidonius.

12h. 34m. Edge of shadow touching the north-east of Tycho, and bisecting Mare Tranquillitatis.

12h. 38m. Shadow passing off Tycho, and skirting the north-east of Mare Crisium.

12h. 40m. North and north-east of moon becoming very coppery coloured.

12h. 45m. Details beneath the shadow coming out distinctly. The principal *maria* and craters quite easy. Moon almost a bright red to naked eye.

12h. 49m. A most beautiful sight. Tycho and the ray system unmistakably seen beneath the shadow.

12h. 55m. Sky clear all round, and stars—even very small ones—coming out with marked distinctness. Aristarchus, now a conspicuously bright spot on eclipsed portion, and all lunar details striking.

12h. 59·5m. Small star occulted at about 25° from north point (rough estimate only).

13h. 0m. Haze gathering round the moon blotting out all stars Coppery colour now much less marked; what trace there is, is on north-west side.

13h. 30m. Moon now almost a deep red, brightening generally east of south.

13h. 35m. Thick haze coming suddenly up from the sea, obscuring stars and giving the moon a dull and uninteresting appearance. This lasted over twenty minutes.

14h. 0m. Beginning once more to clear.

14h. 3m. End of shadow a little to the north of Tycho, and touching south side of Grimaldi.

14h. 5m. Details beneath shadow again very distinct.

14h. 20m. North-west limb a decided copper-colour once more, though duller than before.

14h. 24m. End of shadow across Copernicus, and to the west of Aristarchus.

14h. 35m. End of shadow cutting across the centre of Apennines, and touching the promontory Heraclides on the south-east side of Sinus Iridum.

14h. 44m. End of shadow bisecting both Mare Serenitatis and Plato.

15h. 0m. Edge of shadow again very diffuse. Difficult to note the moment of last contact. It occurred, as nearly as could be made out, at 15h. 8m. The penumbra was distinctly seen for some few minutes after this, when, in view of Sunday duty, I closed the Observatory and retired, well pleased with my continuous watch from 11h. 30m.

One or two general remarks may not be out of place before I conclude this report. The somewhat varying conditions made it quite impossible to note with any accuracy the exact times of disappearance and reappearance of stars.

The slightest cloud or haze caused the moon's disc to become a dirty dark grey; but during such periods as were marked by a perfectly clear sky, the resemblance of the eclipsed moon to that of December 27, 1898, was very remarkable. As a mere spectacle the effect was best when viewed through a good binocular, but the detail in the telescope was very striking. I must once more call attention to the ray systems, especially that radiating from Tycho. It is generally said that these are seen only under high illumination. But this is not so. I have more than once reported in the "E. M." that these have been observed on the dark moon when seen by earthshine; and last year's eclipse revealed these systems during the whole time of totality. This year, as the above notes show, they were again seen whenever the sky was clear of cloud or haze, through the earth's shadow. They are not, therefore, by any means dependent on any high degree of illumination.

May I also use these notes to point a moral? Never retire from the scene because conditions look unpromising. No appearances could have been more disheartening than those of the evening of the 16th inst., yet the eclipse was, on the whole, very nicely seen, and the pleasure to the writer all the greater that his zeal had not been easily quenched.

The next day I was stopped in the road by a kindly-disposed police-sergeant, who said:—"Oh, sir, you should have been out on the promenade last night, or rather this morning about half-past one: *there was a total eclipse on.*" From the tone of voice and look of triumph it was clear that this vigilant officer of the law had congratulated himself on having seen what, to the astronomers, would be a great surprise when it was duly reported. I was, of course, obliged to reply that I had watched the same eclipse through from my observatory in the garden. There was a long-drawn "Oh!" as the constable quietly walked away, as if he had said: "Well, I thought I had caught them napping this time!"

Instrument used, a 5in. Wray equatorial refractor, with a power of 60; also an excellent binocular.

THE PERIODICITY OF SUNSPOTS—THE MINIMUM OF 1878.

[43147.]—I SHALL be glad to supplement my last week's letter by the following few remarks upon the above minimum: I possess a score of *Nautical Almanacs*, but they do not form a consecutive series. Upon looking through the list of six sunspot minima previously observed, I find that the only one which my almanacs cover is that of 1878·5, or July 1 of that year. The exact date is given upon the authority of Proctor. But in *Nature* of May 26, 1898, it is stated by Mr. Ellis (late of the Greenwich Observatory) that the date is 1879·0, or Jan. 1, 1879. Here, then, is a difference of six months in the date as given by two competent authorities. Which of them was right? Were they both right, or only one of them, or neither? What says the theory on the subject? An examination of the *Nautical Almanac* for that year shows that Aug. 12 to Sept. 19 all the six planets nearest the sun were on the descending or down side of their orbits. Between Sept. 25 and Nov. 8 Mercury was on the up side of its orbit. Between Nov. 8 and Dec. 22 all these planets were on the down side, with the exception of Venus, whose orbit is so nearly circular. The theory consequently indicates that there would be a double minimum, the first part between Aug. 12 and Sept. 25, and the second part between Nov. 8 and Dec. 22.

Is it too much to hope that some reader of the "E. M." who has access to sunspot records will take the trouble to compare them with the above?

May I venture to hope that some one who has access to a complete set of *Nautical Almanacs* will examine the position of the planets at the times of the other five recorded minima and report.

Ryvecton, Dec. 22. **W. A.**

THE MOON AND THE WEATHER.

[43148.]—THAT the moon has no appreciable influence on the weather I firmly believe; but still, since the moon produces tides in the ocean, I see no reason why it should not produce tides in the atmosphere also, and so cause general displacements of the air. But we fail to observe corresponding changes in the weather which might result from these displacements; yet there is a meteorological fact that clouds under the full moon tend to disperse, and I think this may be produced by the reflection to the earth of some of the tremendous heat received by the moon from the sun. Moreover, we find that there is a slight preponderance of rain at or near the time of new moon than at the full moon, which would be a natural consequence of a less cloudy sky at the time of full moon. But we have no real evidence, in the present state of our knowledge, of any other influence than this. To the person who says that the moon has no influence on the weather because it is local, I would reply that the moon then has no influence on the ocean tides, because they are local. I have heard of a belief among some useful people that the moon accelerates the circulation of the sap in trees. This may appear reasonable to some people; but when formerly it was supposed that the moon favoured animal putrefaction, and then it was discovered that it was due to moisture, which was always produced on a clear moonlight night—not through any influence of the moon, but owing to a cloudless night, and consequent formation of moisture, then we can have doubt of any

other influence of the moon. There certainly is one *great* influence the moon has, and that is over some people's brains. Why do not such influential people try some other cosmical body—the sun, for instance? We have heard such a lot of funny things lately in the "E. M.," such as watery comets and Leonids destroying Sodom and Gomorrah, and meteors made of salt, that we may now expect to hear that Mars is made of roast beef or turkey, or perhaps plum-pudding; and that the sun is made of whisky, and that the spots in the sun are blackbeetles. Such absurdities in astronomy only set the science up to ridicule, and lower it in the estimation of the laity.

N. M. Munro.

CUTTING-OFF ON A MILLING MACHINE.

[43149.]—Here is a method of doing on a milling machine in a better way certain work that is generally considered screw-machine work, and it is said to be far more economical for cutting studs and pins to a uniform length and square on the ends. The following remarks are by Mr. H. E Harris, and appeared in the *American Machinist;* but I thought they might be useful to your readers, so I send them over at first opportunity. Mr. Harris points out that the screw machine will cut the pins off all right with time; but if the stock varies a little in size and comes small the split chuck has to close up more, and that causes a longer piece to be cut. This trouble, he says, has been obviated in some later designs of chucks. Then our tool has to be ground and set, also causing error, and unless we use two tools there is bound to be a little neck or burr on one end of the piece.

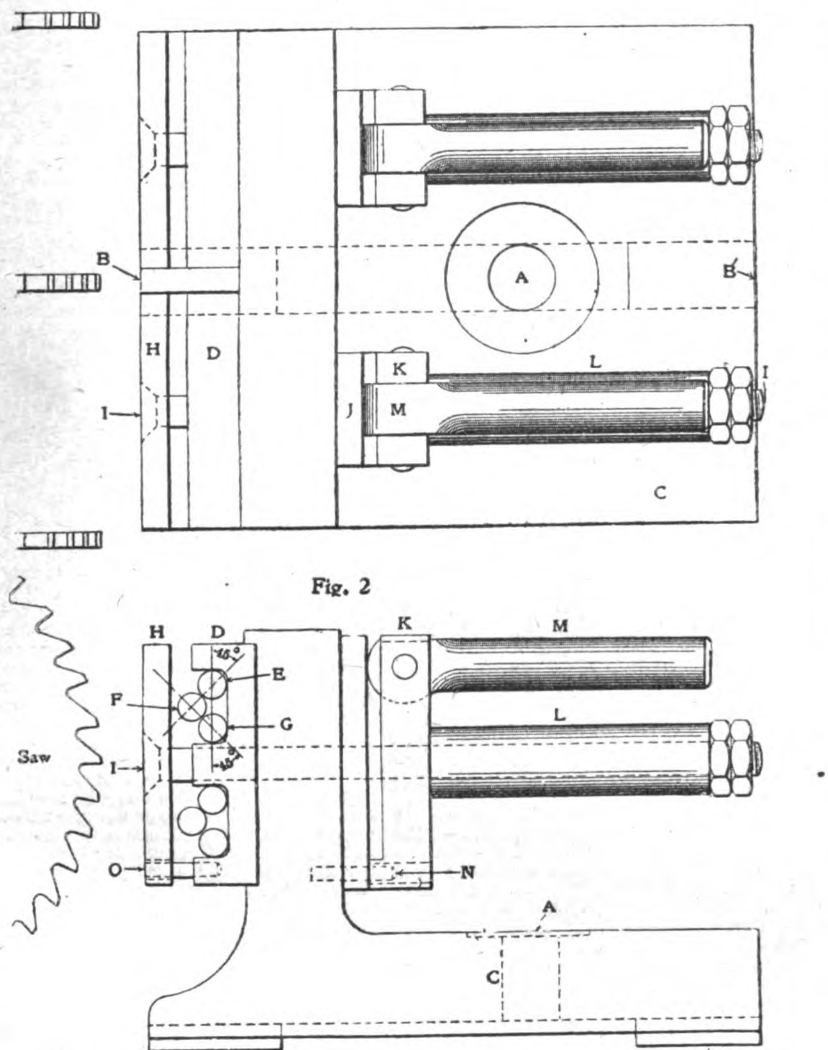

Fig. 2

The arrangement here shown is a gem of its kind, and gives real satisfaction. Our cutters are put on the milling arbor and set to cut the exact length by means of the adjustable collars shown at Fig. 1. The bushing A screws into the bushing B. Both are hardened and ground together, true as to bore and bearing faces. The adjustment is readily made by screwing them together or apart by means of the knurl, or pins inserted in the holes shown at C.

Our fixture (Fig. 2) is clamped to the milling machine table by means of bolts passing through the hole A, and is held in alignment by means of the screwed-on lugs B, B', which fit the slot in the table. The body or angle-piece C is machined only on the face to receive the holder D, and on the bottom. The holder slots are so designed that the line of centres of the touching-rods E, F, and G to

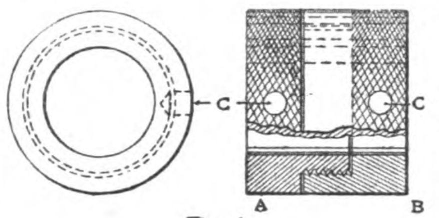

Fig. 1

be clamped and cut off shall set at an angle of 45°. If smaller stock is used, five rods can be set in a slot instead of three; and if shorter pieces are required, more cutters may be used and more pieces cut at a time. Any variation in the size of the stock will be compensated for by the shape of the stock itself, and also by the clamp H, which is held loosely by the head of the clamping-screw I, and is kept from turning by the pin O.

The holder D is screwed to the angle-piece, and is drilled through the centre to let the clamping-screw I pass through. This screw is put through the holder, the angle-piece, the piece J and loosely through the lever K, which should be rounded slightly at the fulcrum end, and the tube L, against which the nuts on its ends bear. These nuts give the adjustment for the proper action of the cam on the end of the cam-lever M. The reason for leaving the tube L long is that it may serve as a grip for the workman to get his fingers around and aid him in bringing down the lever M. The pin N is simply to keep the levers and the piece J from turning around on I. J is used to provide a hard, smooth surface for the fulcrum end of K and the cam to bear against.

We raise our lever M, and that throws the clamp H back. The stock, in rods of convenient length, is inserted from the side, and the lever is then brought down, clamping them securely in place. It then takes but a short motion of the milling-machine table to cut off from six to fifty pieces (varying inversely with the size and length of stock) almost simultaneously. The stock is moved along each time enough to let the cutter nearest the spindle bearing cut off a short piece, and thus prevent any deflection of the cutter or saw.

If the job calls for a tapped hole in one or both ends of the piece, we can afterwards drill them, ten at a clip, in a jig in a multiple-spindle press. The tapping can be then quickly done in a hand-screw machine or a specially-arranged tapping-machine. The materials in the construction of the jig are as follows:—C is of cast iron; B, B' and L of machine steel; K of case-hardened machine steel; D, H and J of hardened tool steel; M of tool steel hardened at the cam end, and I of tool steel.

It seems to me to be a valuable arrangement, so I send it on.

Sterling, Ill. J. B.

PRESERVING BRASSWORK FROM CORROSION.

[43150.]—The paragraph with this heading on page 433 reminds me of an idea which occurred to me some years ago when reading a paper on Pigments published by the Society of Arts.

The lecturer had found that in the majority of cases the varnish used for pictures was not absolutely damp-proof, but that in old pictures in which the colours were still bright, the varnish *was* damp-proof. He concluded that damp was the cause of faded pictures, and set to work to find which varnish answered the purpose of excluding it. He found—if I recollect rightly—there was no such varnish on the market; all allowed damp to get through minute holes or pores in the dry varnish! He experimented by dehydrating some sulphate of copper so as to get rid of the blue colour, and then mixing it with the varnish to be tested. A little painted over a glass slip was examined from time to time, and the goodness or otherwise of the varnish was shown by the time necessary for sufficient damp to penetrate to turn the "bluestone" blue again.

After trying a number of mixtures he at last found that the addition of a minute quantity of Venice turpentine conferred the desired property on the varnish. It appeared to stop up the interstices I have referred to.

Now would Venice turpentine answer as well with lacquer? The heating may spoil its effect. Will someone try and report the result? Glatton.

PLASTICITY.

[43151.]—The title which I have used for this paper is derived from the Greek language. From *plastikos* = fit for moulding; or from *plastos* = formed, moulded; or from *plasso* = to form, to mould, and that is having the power or property of giving form or fashion to the mass of matter. So far the dictionary. Thus plastic clay was in geological parlance used for a clay that was capable of being moulded or formed when wet. So, as clay when wet was plastic, any kind of earth which contained clay becomes plastic or yields a matter, which like dough, can be readily moulded into form. As we mould clay into clay pies when we are young, and I presume all of us were young enough to form clay pies or mud pies at some period of our existance, so we were practising plasticity then. And our minds were plastic enough also, and only formed, as it is said, by the plasticity.

The plasticity of clay was known to the ancients; that is to say, as man came to feel the clay when moist with water, he saw that it could be moulded into forms, and so he made the first vessels of unburned clay to form his cups and plates, and we have in the aborigines the clay that was thus moulded, sometimes on the inside of straw baskets before they had wheels to fashion the clay upon. These baskets were sometimes burnt off, and thus the clay was rendered hard, being burnt clay. Of course, when the clay was white or blue and pure, the objects were porcelain. But we do not have porcelain vessels amongst the ancients. And we have the aboriginal clay vessels unbaked. They were first made by moulding without baskets; but when baskets were formed it was seen that they could be lined interiorly with clay. This clay was at last burnt off and the baked clay vessel left. The origin of pottery, which was the name the art received, is unknown and hidden in darkness, but this was the manner it grew. At least such is the case with North American aborigines.

But the plasticity of clay when wet with water brings us to the knowledge of still another fact, and that is that the solid crust of the earth is not solid at all. That the word "solid," when applied to the earth, is a misnomer. That it is plastic and very plastic too. Let us see how hard rock, granite, for instance, which is thought to be so solid and inflexible, can be moulded into forms. If we look closely at a piece of granite we find in it traces of its being elastic, of bending. The particles can be pushed out of place. The quartz and felspar,

although seeming so fixed, have been moved out of their relative positions. Granite is crystalline, showing that it must have been plastic from solution or fusion some time ago. And gneiss, which is formed of mica mostly, shows the bending very clearly. The mica is very elastic, springing to its places when bent by a slight pressure.

And upheavals of the earth, or earthquakes, are very common everywhere, being heard from, single or many, in every quarter of the globe. These are caused by the contraction of the globe; most likely by the cooling, and the earth is thus thrown into folds or crumpled up. So when the ice or glacial period came, the ice itself accumulated to a depth of one or more thousand feet on the surface of the earth. To the weight of the load of this has been attributed by Jameison and Warren Upham and others to the succeeding subsidence of the same called glaciated regions. This caused a period which has been called by Hitchcock the Champlain period, from the locality on the shore of Lake Champlain between Vermont and New York, where he first studied it. We will have to speak of this Champlain period and the clays laid down in them later on.

At all events, the earth and rocks also can be bent, or are plastic very evidently when we look closely at them. So that the term solid rock is a misnomer, and we must put it aside, and not use it. Now, as the earth during the ice or glacial period was thus elastic, before the Glacial period, in the miocene period, or what is known as the Tertiary by the older geologists, and was higher, nearer the sun, the source of heat, and therefore the temperature was affected, and it was hotter also. That is to say, they had a warmer climate than now in the same zone. But the ice of the Glacial period accumulated, not over that section of the country where the Miocene or Miocene rocks appear now, but where the older rocks, and where they were still higher, when they passed beyond the influence of the sun and came into the region of perpetual snow. In the temperature it was very cold all the time, as it is now in the regions of perpetual snow in the mountains. In fact, there were high mountains then, and the ice accumulated on them, The Laurentian mountains in Canada, the Adirondack mountains in northern New York, the Apalachian mountains, and the Cordellarian mountains, besides small ranges of mountains in various parts of the country, so that we find glaciers, which were formed in these various places. And they began to move, as glaciers do now, down the mountain sides into the valleys below, from the centres of glaciation, east and west, and to the south and south-east, for this is the way they went, not to the north, for the Laurentian range of mountains, extended across almost the whole continent. These turned the whole tide of the glacier to the south-east, whilst the Cordillarian mountains in Western British America, lying south and north, turned it into the Pacific Ocean.

They left their traces on the rocks, and deposited boulders and gravel, and mud and clay on all sides of the elevated land. The clay was pushed before the advancing ice, and rendered turbid the stream that flowed, making lakes or lakelets on the borders. The boulders and gravel were deposited first, the mud, which consisted of fine sand, next, and the clay eventually last, as we see it. In fact, in some places in New York and New Jersey, where I have studied it, the gravel and clay are very well marked and distinct. Now, when the ice melted, it broke off at the margin, and formed icebergs, as they are called, which floated away to melt gradually, and the ice was not clear, but had mud and clay immersed in it, and when it melted the water was cloudy by reason of the clay suspended in it, and it formed a milky water which was at the temperature of melting ice (1° C.), and then floated away to mingle with the clear water of the ocean near by. At this temperature the bacillaria, which are minute organisms which have been ranked first as animals, and then vegetables, and, lastly, as protista, flourished. They flourish most common when it is not very warm—in fact, in spring. When they died they deposited their shells, which are thus made up of the same substance almost as clay, and formed the various fresh-water infusorial earths, the lacustrine sedimentary, the diatomaceous deposits, the bacillarian layers that are so common and prized by microscopists everywhere. This was the iceberg clay period of the modern geologist.

Can we wonder that "species" of the so-called diatomaceæ or bacillaria are the same? Be they gathered in Italy at Santa Fiore, in France in the Auvergne, in Germany at Berlin or elsewhere, in Great Britain at Aberdeen or Mull or Lough Mourne, and in North America at South Beddington, in Maine, in New Hampshire, or Weequachih Lake in New Jersey, or the hundred other localities in which they are found. And can we wonder that the bacillaria are living now in every stream and pond, in lakes and rivers, in fact in the ocean, are the direct descendants of those which were living in the iceberg age period, which is the Glacial period also. So they lived, unchanged by evolution or other means, from that period until now. In fact, they are fresh-water forms now, owing to the plasticity of the earth.

Beyond the Glacial period they also lived back into the Silurian, unchanged in outline still, and I have shown how they came, but from what they came cannot, of course, now be determined. It can be found out undoubtedly by studying the living bacillaria, and it can be seen that they were evoluted, so to speak, from a simple form that has been called protococcus—the green slime of the marshes, meadows, and rocks, or woods.

In this country the ice when it melted formed a vast lake or sea that covered all of the region from the Rocky mountains to the sea and the north of Mexico to British America. This is known as the Occidental sea, and was fresh water and formed at the temperature of melting ice, in fact in the iceberg period. The so-called "species" are different from those on the east coast in Nova Scotia, Maine, New Hampshire, and New Jersey, but are the same over the region of the Occidental sea. Perhaps as time goes on they will be discovered in South America and the region of the southern ice sheet thus be shown. In fact they have been already discovered by Darwin in Patagonia.

Thus the plasticity of the so-called solid earth is shown, and mountains are elevated and obliterated and glaciers are seen now at Mount St. Elias and in Greenland.

Arthur M. Edwards, M.D., F.L.S.

IS THE THEORY OF GRAVITATION A FINALITY?

[43152.]—MATHEMATICIANS tell us that "all the celestial motions are explained by the one law of universal gravitation." But is this strictly correct? Does the law of gravitation explain the rotation of the sun upon its axis, or that of the earth and the planets? Did Newton profess to have explained the cause of the sun's or the earth's rotation by his theory? It seems to me that each of these questions must be answered in the negative. The task which Newton originally undertook seems to have been to account for Kepler's laws of planetary motion—i.e., to explain the cause of the orbital motion of the planets only, leaving unexplained their independent axial rotation. He also claimed to have discovered the *mathematical* cause only of the planetary orbits, an admission which implies that the real or *physical* cause remained untouched by his theory. Indeed, to this day mathematicians speak of gravity as a mystery, which virtually amounts to the confession that the true cause of the celestial motions have yet to be discovered. The correlation of the so-called physical forces now known to exist and to play such an important part in the economy of the world, but what is still only partially and imperfectly understood, was wholly unknown to Newton, Laplace, and all our great mathematicians who lived prior to the present generation. And even during the present century, as Lord Kelvin pointed out 30 years ago, the geology of Hutton, Playfair, and Lyell is diametrically opposed to that held by our great mathematicians and natural philosophers. (See article on "Geological Reform" in Huxley's "Lay Sermons.")

Taking these things into consideration, it is not too much to say that the theory of gravitation does not embrace and explain the whole of the phenomena, and consequently it is not the finality so often attributed to it.

That I am not merely writing at random the following quotation will suffice to prove:—"The generalisation gravity leaves behind it a sense of mystery unsolved, *as if there were something further that we might arrive at* if obstacles did not intervene. Newton himself seemed unable to acquiesce in gravity as an ultimate fact." (Bain's "Logic," Vol. II. p. 125.)

This frank admission, however, is most exceptional. Mathematics, as a rule, will not allow that the theory is in the least degree imperfect, and speak of it as if it were a full and final explanation of every known movement possessed by the heavenly bodies, regardless of the fact that it affords us no explanation at all of the earth's diurnal rotation. No one has been able to explain by means of the theory of gravitation why the moon so revolves around the earth as to always present the same face to us. And even supposing this peculiarity to be accounted for by the law of gravitation, the same law would not account for the converse—i.e., the motion of a planet round its primary so as to expose its whole surface periodically to the central body—which occurs in the case of the relations of the Earth, Mars, Jupiter, and Saturn to the Sun. There are other anomalies also which cannot be explained on the theory of gravitation. The moon, for example, during a lunation, *cæteris paribus*, is nearly half-a-million miles nearer to the sun when she is new than when she is full, and yet her velocity is as great in the latter position as in the former. Supposing this had not been discovered by observation, would mathematicians have anticipated the effect of solar perturbation on the theory of gravitation? Would they not have unanimously come to the conclusion that the moon's velocity would be at its maximum when the moon is new and nearest to the sun, and at its minimum when she is full and at her farthest distance from that body? A similar anomaly presents itself in the phenomena of the tides. Who would have supposed, on the theory of mutual attraction, that the moon would apparently generate tides simultaneously at the antipodes? Or that the sun and moon would generate spring tides when in opposition, as well as when they are in conjunction? With these and other irregularities, well known to be insufficiently explained by the theory of gravitation, I have no hesitation in saying that it is not true to say that "*all* the celestial motions are explained by the one law of universal gravitation."

The accuracy with which astronomers are able to predict the tides and eclipses is sometimes very improperly attributed to the theory of gravitation. The absurdity of this claim on behalf of any theory has been convincingly proved by Mr. Hopkins, who says: "Mathematicians think that the celestial bodies are sustained in their orbits by means of an original impulse given to them, combined with a centripetal force, and not according to the principles we observe in terrestrial physics. They have laws of motion peculiar to themselves, which have been assumed and blended with the laws of geometry. Indeed, so far as physics are concerned, it matters not much what hypothesis may be adopted in astronomical phenomena, provided our calculations be founded on uniform spaces and velocities, and the whole are reduced to the laws of proportion which subsist between sines and cosines, and not in the least depending upon the laws of physics. Many persons who read and admire the degree of consistency of our almanacs in predicting the eclipses and tides, &c., suppose that such predictions are founded on the law of gravitation; but the fact is that such calculations are entirely dependent upon direct observations of the periodical movements of the heavenly bodies, and have nothing to do with the physical theories of philosophers. *The ancients made similar calculations at a period when their doctrines were very different.*" ("On Terrestrial Magnetism," p. 174.)

That gravitational astronomy is but a partial explanation of the facts becomes still more conspicuous when we compare it with descriptive and observational astronomy. As everyone knows, the physical constitution of the moon differs greatly from that of the earth, and even more so from that of the sun; but gravitational astronomy does not take into account these differences. And, again, everyone knows that the physical influence of the sun differs very remarkably from that of the moon. The former is an immense source of dynamical energy to the earth in the form of heat; but our satellite gives us no sensible heat whatever, and, therefore, cannot be a source of dynamical energy to us. This difference is not taken into consideration by gravitational astronomy. On this theory similarity only is recognised. The heavenly bodies are supposed to be of an exactly similar nature, and are supposed to act and react upon each other by means of an exactly similar force, or species of energy called gravity.

No philosophers have more strongly insisted upon the importance of attaching due weight to those facts which differ from, as well as those which agree with, any general theory in physical science than mathematicians themselves. The following is a sample of many similar quotations, that might be adduced from the writings of our great mathematicians, touching upon this point:—"It has often been noticed that many of the great discoveries in science have had their origin in nice observation and explanation of minute departures from some law approximately true." (Ball's "System of the Heavens," p. 108.)

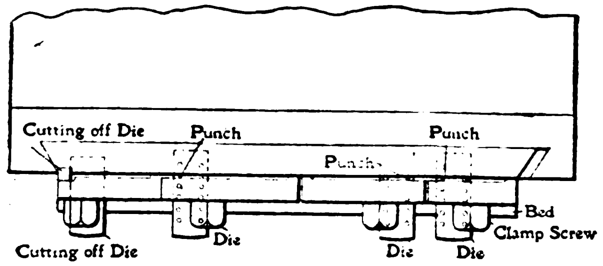
Gravity has hitherto been regarded as a simple and unique force. But can this view be any longer seriously maintained? Gravity must be related in some way or other to magnetism, electricity, and heat. Such potent agents in the production of motion will certainly have to be included in any complete theory of celestial dynamics. So long as they are excluded out of a kind of superstitious reverence for authority, the explanation of the cause of the motions of the heavenly bodies must remain imperfect and incomplete.

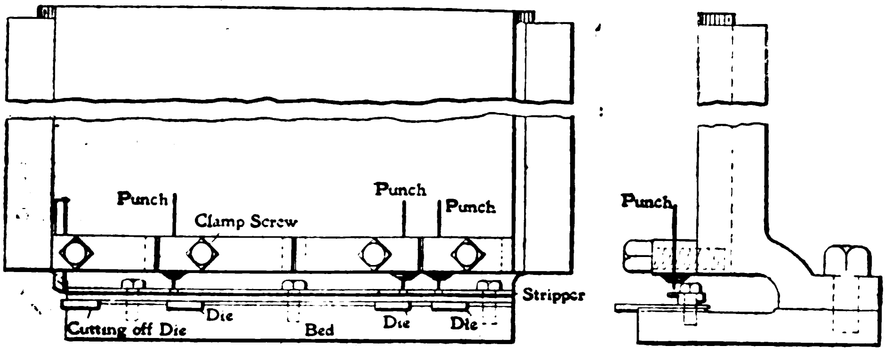
What mathematicians call gravity, and regard as a unique force, ought, in my opinion, to be treated as a dual force—similar to, it if not identical with, electricity.

Supposing gravity to consist of repulsion as well as attraction, would not the former force be concealed or masked, as a rule, by the greater force of attraction, as in the case of magnetic induction, which always gives rise to repulsion as well as attraction?

This supposition, if it could be proved by a comparison with the facts, would remove gravity from the isolated position that it has hitherto occupied, by showing it to be a natural agent familiar to us all, instead of a mysterious force ill-understood even by mathematicians.

The theory of gravity as a dual force would not affect the law that action and reaction are equal and opposite in the least; neither would it affect the law of the inverse square as the measure of the intensity of any natural force diffused from or converging to a fixed point. The law of gravitation, expressed in abstract terms, would be amplified, but





not invalidated, if gravity were regarded as identical with electricity, as the attractions and repulsions between two electrified bodies are inversely as the square of their distances. If the celestial bodies are electrified bodies, this law will apply to them as surely as it applies to terrestrial bodies.

If gravity is a dual force, it is easy to explain the apparently irregular behaviour of the moon during her second and third quarters. The solar attraction and repulsion would be in equilibrium when the moon and earth are equidistant from the sun. His attraction, however, would predominate when the moon is within, and his repulsion would predominate when the moon is outside, the earth's orbit. Hence the variation from quadrature to syzygy, and vice versâ, which is so perplexing on the theory of attraction alone. The co-existence of the two forces explains the fact that the matter of the tail of a comet is repelled instead of being attracted by the sun, and may also be found to account for the planetary orbits better than the current theory.

Hall-street, Halifax. **Hugh Alexander.**

SHEARING AND PUNCHING SMALL SPRING STEEL.

[43153.]—As I have seen many inquiries in the English Mechanic about the methods of working spring steel, I send you the following which may be of use to your readers, and may possibly bring out some useful comments. I found the remarks in the *American Machinist*, to which paper they were contributed by Mr. C. E. Quimby a few weeks ago. The sketches show a sub-press and set of dies made to punch and cut off flat spring-tempered steel about ⅛in. wide and $\frac{1}{32}$in. thick. The temper of the steel is somewhat lower than that of an oil-tempered spring drawn by burning off the oil yet is hard enough not to cut easily. As the work wears out the dies and punches very quickly, it was necessary to adopt a design that would permit a rapid change of either or of both, to replace broken ones, and the easy removal of punches for sharpening. The punches are straight pieces of "drill rod," about 4in. long, hardened in water and drawn to a blue in the middle, where the pressure of the holding-clamp tends to break them, and the ends left a very light straw colour. They do not need to be very straight, as the clamps are smooth, and by placing the punch in the clamp with the curve to right or left, the end will be in the same plane as if the punch was straight. They are sharpened on both ends, and, when dull, are reversed, thereby saving trips to the grinder.

The dies are ⅛in. thick and ½in. wide, and have no finish except to grind the scale off the top side and true the edges with a file to fairly fit the recess in the bed. The holes are drilled in a jig, and the only accuracy called for is that they shall be true to size and the same distance from the nearest edge of the die. The die is first placed in the jig, and each hole started, then removed from the jig and drilled through with a drill smaller than the required size. Clearance is secured by drilling about two-thirds through from the back side, and then a sizing drill through each hole completes the die. They are hardened in water, drawn to a light straw colour, and the top ground smooth on a grindstone in water. This leaves the holes smooth and very sharp.

The stripper and gauge are in one piece, and the work is held against the gauge by light springs, near each punch, on the front side. The dies are not let into the bed quite their full thickness. The combined gauge and stripper being screwed down upon them holds them in place. The holding-down screws are so located that any one die may be removed, without disturbing any other, by loosening the nearest screw and springing the stripper up a little.

Should the hole in the die become worn by use, so that the work comes off rough or with a slight burr, the stripper-holding screw is loosened and the die pushed in until a new hole is under the punch, the punch lowered until it enters the die, and the die carefully moved in or out until the punch, upon repeated trials, enters the die freely, when the holding screw is tightened and the work proceeds.

When the punch becomes worn or breaks off, it is removed and about ⅛in. broken off to remove the worn or slivered end, the end again ground square and the punch returned to its place, the press being in its lowest position when the punch is clamped.

In setting both punch and die at the same time, the die is first slipped into place, the punch entered in the die and clamped, and then the stripper is tightened down on the die.

The punches are only fifty-one thousandths of an inch in diameter, and are a close fit in the dies, usually requiring a little pressure or a light blow on the upper end to force them into the die when both are new.

The sub-press shown sits under the gate of an old press that gives it the necessary motion, and an attachment automatically feeds the wire. The slide is disconnected when setting a punch or die, and can be easily moved by hand to feel if the punch enters the die properly.

We think this construction is unusual, and quite a departure from the accepted methods of holding dies and punches, but it serves the purpose admirably. The punches usually make from 1,000 to 5,000 holes without sharpening, and have at times made 10,000 holes each, at the rate of 110 per minute. The dies make from 5,000 to 50,000 holes for each hole in the die. A number of these sub-presses are in use for different lengths, styles, and sizes of the pieces made from the steel. They have been used for about ten years, and are satisfactory in every way. The work is uniform, accurate to gauge, and, considering the hard and trying nature of the material worked upon, is cheaply produced. The sketch is not made to scale, but shows approximate proportions and the relation of the parts.

It seems to me that the above is a useful method, while the hints about the temper of the punches are valuable.

Cleveland, Ohio. **J. Swan.**

BIBLICAL SCIENCE.

[43154.]—One is disposed to deprecate the discussion of the Deluge, Destruction of Sodom, and Scriptural questions in general. It cannot be free, and is rarely fair. More than the fear of being called heretical, and what not, is that of offending many devout and worthy persons who are still deeply pained at any doubt thrown on the entire infallibility of the Bible. A friend of mine lately delivered a lecture on the Solar System, the evolution of worlds, and life—ordinary commonplaces to the readers of this journal. It was within six miles of a large manufacturing town. But two denunciatory sermons were preached against him in the village chapel. The preacher went about proclaiming that Mr. —— "ought to be stopped," and my friend was privileged, in a small way, to become a martyr of science.

Mr. Garbett, whom we could so ill spare, must not be offended at his readers for refusing to accept his implicit fundamental assertion of the special historical authority of the Jewish books. With Moses we must deal as with Livy; allow the credible, reject the incredible. There is nothing irreligious in this; nor in reasonable interpretations of statements in the light of the condition of knowledge at the time they were penned. The Bible is not one book, but a library of books, composed, or compiled, at widely separated times. Whether we hold it to be inspired, or only a collection of the highest known teachings for the moral elevation of the race, it cannot but show the development from lower to higher of both science and morality. Experience and natural religion show that man's Maker has certainly left the slow growth of knowledge to be the result of man's own discovery. Otherwise there would have been revealed to him the use of steam and the secret of healing disease. And, consistently, the inspired teacher must be left to use, for his framework of illustration for enforcing reverence and duty, only the secular knowledge and science of his day. Otherwise two things must follow. In that day his teaching would be utterly rejected, and in future time the book containing it could be only treated as a forgery. In view of the moral purpose—the call to reverence and restraint—premature disclosures of knowledge accessible to man's natural faculties would defeat the end of supernatural revelation, which deals with what is inaccessible, and leaves the domain of sensible nature to revelation by his own painful effort.

So, I take it, a preacher of old had in hand to tell of punishment following evil doing, and used an accepted tradition of a great calamity in days of wickedness. Both the evil and the natural event are only too credible; and that some punishment must follow the evil, though it be not a flood, is certain. Only the particular connection and the details are mythical—a tapestry woven out of threads of primitive beliefs. I contend that all ancient wide-spread traditions are echoes of facts, precious histories buried and smothered in accretions, and all the more interesting for that. The Biblical story is one only of several accounts of the Flood among the people betweeen Persia and the Syrian Desert. It prevailed in other lands. We read that the date asserted for it is the date of the Hindoo festival of the dead, and the same in Australia; among the Egyptians the festival in honour of the dead; the Persian month of the Angel of Death; the Druidical three days' festival for the dead, when every light was put out, and the phantoms flocked through the air to the boats that carried them to the abode of the gods, and the time when the Aztecs offered solemn human sacrifice against the destruction of the world, as their tradition alleged, had, at that time, occurred of old. This means only that there *had* been a flood, and vast, in some remotest time, before the earliest now surviving species of man began his migrations to the ends of the earth, carrying the great tradition of their common ancestry. But we are sure that to those earliest men their locality must have been the world, the unknown beyond being not even conceived. Then the late version of a Semitic tribe decks the story, and explains it with Oriental fancy, and fits it to the ancient notion of the solid heaven arching over the little plain of earth, bearing sun and moon for his sole use, and the little stars to amuse him. That vault of which, long after, falling stars were broken bits. Beyond that vault was water, far later taught to be the element from which all was made. "God made the firmament (Josephus says 'a crystalline'), and divided the waters which were under from the waters above." "The windows of heaven were opened" "and were stopped." Josephus has it, "it became 15 cubits higher than the earth," speaking plainly of an earth like an island, flat and surrounded with ocean, inside the shell, as believed in his time; and quotes Berosus, "There is still some part of this ship in Armenia, and some people carry off pieces of the bitumen." The small view of a small universe and its ruler can be seen in his curious expression. "But when God came into the garden, Adam went out of the way. This surprised God, and he asked what was the cause." We have a grander idea of both, and a more reverent interpretation of the working of the Creator's law.

The destruction of Sodom has the same teaching, the same distortion of tradition, the same accommodation to the opinions of the time. We interpret the tradition according to the knowledge and convictions of ours. It is to be reasonably taken as the, perhaps long post-dated, memory of the actual volcanic rending and upheaval which severed the Jordan from its ancient exit to the Red Sea, and formed the "asphaltic lake." The topography bears that out.

If we choose to indulge our fancy with speculation, we may, declining to be tied to archaic chronology any more than science, picture a great catastrophe long ago, connecting both these dim histories as parts of one event, of which the geological puzzles of the origin of the West Asian inland seas, the vast rendings that appear to have

cleft the courses of Thibetan and Chinese rivers, and the strange entombments of the Siberian mammoth may be traces. Gossip.

RODINAL AS A DEVELOPER.

[43155.]—I SHOULD like to know what are the experiences of your readers with rodinal as a developer. Mr. Thomas, F.R.P.S., says in the *British Journal of Photography* :—

Of this particular developer more has been used in my own practice since its introduction than of any other developing agent, although it is by no means the only one I use, for, indeed, there are but two of the late introductions, diogen and kachin, which have not been tested, and tested as I prefer to test any such matter, not by using it on two or three specially-exposed plates, and upon the results basing one's opinions of its usefulness or otherwise, but by making up some amount of it in stock solutions, and employing it for plates, exposed in the ordinary manner, out of doors, and under such conditions as one's work is mainly undertaken under, and continued over some reasonable length of time; for, however clever a photographer the experimenter may be, it is impossible to pick up and at once employ any strange reducing agent with the same facility as those which constant use has given complete control over. The more is this so when any radical change has been made either in the manner of its working or nature of the resulting negatives given.

Each new developing salt introduced to us comes with its accompaniment of high-strung praise over its wonderful qualities, then a few letters, and, it may be, one or two articles appear, followed later by the usual crop of complaints. So was it with Rodinal; but its chief, if not only, sin seems to lie in some supposed difficulty to obtain dense negatives. No greater mistake could be made, for density may be built up as readily with it as with any other developer, if it be desired and means taken to insure it.

What I like about it in particular is the simplicity and readiness with which any variation is possible, for, being highly concentrated, and in one solution, at a moment's notice either negative-making, bromide enlargements, or lantern slides may be dealt with, the only difference being a more copious dilution with water of this developer is advisable when paper or slides are being treated than when making negatives, with regard to which, by the way, some considerable correspondence lately has been carried on in the photographic press relative to that highly-important topic, Should a developing solution be used more than once? it produced some interesting, and certainly amusing, reading, one side holding, with true British doggedness, that, after having once done its work on a plate, a developer should be consigned to its resting-place, the dark-room sink, while others asserted the contrary, and for a time right merrily waged the wordy warfare.

To me it was intensely amusing, for just about the time I had five dozen exposed plates awaiting development, and hitherto it had been my practice, when anything like a batch of, say, one dozen or more were dealt with at the time, to mix up my developers, and proceed gaily to pass one plate after another through, until either the whole batch were finished, or development became slower, when the addition of 10 or 20 minims from the stock bottle set matters going briskly again. Such had been my practice in a general way, and, in spite of the woes and evils supposed to follow such a practice, past experience seemed to justify the risk, and four dozen exposed plates were in one evening transformed into 47 decent, respectable-looking negatives, most, if not all, of which possess some measure of success, if Mr. Chapman Jones's definition of that desirable article, the perfect negative, be a correct one—viz., that it is pure silver in clean gelatine for all through the series of 23 whole-plates and 24 quarter-plates. So far as diversity of subject, exposure, and so forth would allow, they presented a uniformity of colour, density, and general good quality which left little to be desired, and certainly no cause of complaint; yet for this batch I had used the selfsame solutions right through, with only, as already pointed out, one or two additions from the stock solution to revive its developing action.

Some slight discoloration necessarily takes place when a number of plates are passed through the same developer, whatever it may be composed of; but, with rodinal, and indeed pretty nearly any of those reducing agents of kindred nature, this appears to have no detrimental effect upon plate or film submitted to its action, which is certainly not the case when pyro is employed; and where this particular developer, pyro, is the one used, there can be no doubt of the better plan being to treat each plate with a freshly-made solution, for the simple reason oxidation quickly transforms a pyro developer into a dirty, muddy concoction, unless a large percentage of sulphite has been employed as a preservative.

One reason why difficulty arises, when developing plates with rodinal, to obtain ample density, is because, as a rule, it is used considerably diluted, and time is not allowed for it to build up sufficient density, which, by the way, is somewhat slowly, *if the developer is being used weak*, where, for any reason, exposed plates are first treated with dilute rodinal, after such detail has been brought out as may be thought desirable, density may rapidly be obtained, either by adding rodinal from the stock, or transferring the plate to another dish containing 1 part of rodinal to 10 or 15 parts water, to which has been added sufficient potassium bromide to hold in check its action. In this manner density may be obtained quite as quickly and effectually with this developer as when employing any other. In the same way, where plates submitted to it are found to have been much over-exposed, they may likewise be transferred to the strong and restrained developer just referred to, when development will proceed more correctly, and the results should prove quite satisfactory.

On the other hand, where either excessive contrasts in the subject itself, or brought about by insufficient exposure having been given the plate, the effects of this evil may be much reduced by employing a developer considerably weaker than normal; for instance, 1 part of rodinal may be added to 60 or 90 parts water. A batch of plates may then be submitted to it, and practically we have "stand development, for which I have found nothing more convenient when dealing with small sizes, such as quarter-plate, than one of the glazed pot tanks sold by all dealers, and used for fixing or aluming negatives in. A dozen plates may then be treated at once by placing them in the grooved tank, with sufficient of this dilute developer to cover them; then a tray or lid, or, indeed, anything, being placed over the tank, one may go about other matters, and feel perfectly certain no harm is likely to occur if, from time to time, examination be made, and such negatives as have progressed sufficiently be fixed and washed in the usual way. One matter, however, should not be forgotten, plates developed with this or similar reagents are rather deceptive as to density, and need to be carried apparently further than where pyro, or even hydroquinone, has been used. So also, for some reason or other, when developing in the manner just referred to, they are better for being carried slightly further than when developed with a solution of normal strength. Curious as it seems, the fact remains, and should be noted when commencing stand development.

Used for developing prints on bromide paper (contact or enlarged), it gives pearly greys and good rich blue-black, while for lantern-slide work it needs development carried very far indeed before the shadows become blocked, when the developer is used reasonably dilute, say 1 in 40.

A curious effect was noted some time back while making a series of lantern slides, many of which were given full exposures, and so developed as to get the brightest red colour possible. The plates were Paget's slow, and, having towards the end become rather weary, I hurried up development of the last ten or twelve slides by adding a few drops of rodinal to the slow-acting developer in which they had been. The small transparencies at the moment under treatment were very red in colour, but after the slight addition of rodinal it rapidly cooled down to a pleasant brown, and having several duplicate exposures, by varying the amount of rodinal added to the developer, specially intended to produce a maximum warmth of colour, showed that, as it was added in greater or less quantities, so did the vivid red slide rapidly alter in colour, and, if pushed by the addition of much rodinal, and allowed time, they seemed to turn to a rich warm black. Some of the resulting slides treated in this manner turned out a beautiful rich, warm sepia, while others, having had just the same lengthy exposures, but developed straight away in rodinal, gave a warm black image, and I can well imagine, to first partially develop for bright red colour, and then cool it down, by a brief immersion in rodinal developer, would prove a useful method of obtaining any desired warmth of colour between black and red entirely by development, with considerable certainty, and in a speedy manner.

A commendable feature also about this developer is its sociability, for it will mix with and work in conjunction with any other developing agent I have used, and from its all-round usefulness, should find a place on the shelf of every practical photographer, be he professional or amateur. T. R.

TELESCOPES, GREGORIAN, AND DIALYTE: TO "HIPPALUS."

[43156.]—WITH a preliminary word of thanks to "Hippalus" for his courtesy, I will try to say a little about the points that he refers to in his letter 48129. As "Ell Hay" uses his telescope as a Newtonian, the large mirror must be a parabola, and to use it also as a Gregorian the small mirror must be an ellipse. It would, therefore, be specially interesting if "Ell Hay" would tell us how he secured this curve, whether by a happy accident or by repeated trials, and in what way the small mirror was tested during working. Hitherto, we have had results; but no methods given by which such remarkably good results were attained.

Though I say the small mirror should be an ellipse, on the authority of many writers, I do not myself think this true when the image has an appreciable size; but the point needs investigation, as I formerly stated.

As regards cast and wrought discs, the former can be cast approximately to the required curve, which saves labour; but I have heard that the rolled plate is more equable in texture, and, therefore, better to work. I may also warn "Hippalus" not to attempt to stiffen a cast disc by ribs at the back, as Mr. Wassell found them do more harm than good. Messrs. Chance used to supply cast discs, and would probably do so now.

Now I want help myself. Could a fluid lens be constructed of two capsules of glass containing fluoric acid, the acid being previously saturated with glass so as not to affect the containing capsules? The form might be that of a dialyte, or possibly a compound o.g. might be constructed, using different kinds of glass to saturate the acid. I admit the idea seems hardly practicable; but I venture to thus throw out the suggestion.

If "Hippalus" can keep a secret, I will confess that I think more has been made of the "Schaeberle aberration" than it deserves, so far as telescopes of ordinary proportions are concerned. A. S. L.

SPLICING.

[43157.]—MY letter (43113) was written in no carping spirit. In 1892, "J. H." says "the splice is carried over a length of 4ft. or 5ft.; in exactly the same year another writer advises it to be carried over 84ft. I admit that the first applies to a cotton rope, the other to a wire rope, and that a greater length is required for splice in a wire rope; but certainly not twenty times as much. It was this great difference that impelled me to ask "J. H." to give us the benefit of his experience.

I fail to see where he would lay himself open to the charge of "repeating himself." Seven years brings a generation of new readers, and I don't see why the jointing of ropes should not have a place in "Millwright's Work" as well as the jointing of belts.

I take it from the latter part of his letter, with the Editor's permission, he would be willing to write a special article on "splicing," which I hope our Editor will grant. Richard Pudson.

ECCENTRIC CHUCK.

[43158.]—I HAVE read with great pleasure and profit the able series of articles on the spherical sliding-rest by Mr. Evans. I feel sure a hearty vote of thanks is due to him from all amateurs. If we should not encroach too much on his kindness, might we ask for a detailed description and drawings of the geometric chuck?—a difficult piece of work, but I hope not beyond the capabilities of some of the readers of the "E. M." E.

ERRATUM.—"Poison in Fish." In letter on p. 407, for "*his*" read "six." Glatton.

REPLIES TO QUERIES.

*** *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[96727.]—**Elementary Optics** (U.Q.)—Rays proceed from any given point, *a*, on the object to all parts of the lens. They converge again until they meet again at a certain distance corresponding to the proper position of the screen. At any intermediate point these images of the point are still separated, and produce a blurred picture. Similarly the rays from another point *b* converge at the same distance from the lens, and are blurred elsewhere. The images of the points *a* and *b* are usually further apart, of course, than the points themselves, which is what probably made the querist picture single rays from each point diverging in space instead of a multiplicity of them. GLATTON.

[96740.]—**Efficiency of Small Gas-Engines** (U.Q.)—I am sorry I have not the figures by me, but "Improver" will find the efficiency of a small engine—though less than that of a large one—is not nearly so much less as in a steam-engine. GLATTON.

[96751.]—**Diving** (U.Q.)—I remember seeing in *Science Siftings* the statement that lenticular glass vessels filled with air enabled an observer to see under water without the distortion and indistinctness usually observed. Can any reader confirm this, or quote the passage? GLATTON.

[96779.]—**Boiler** (U.Q.)—If your boiler is a water-tube one, copper and brass are both bad. Brass gets brittle, and so does copper. In the latter case it is due to deoxidation of the metal. (Copper is tough only so long as it contains a certain proportion of oxygen.) If this boiler is a fire-tube one, brass or copper will do well, since the flames

will not enter the tubes much without being extinguished. There are plenty of patented automatic-feed regulators made. I doubt if a very small one would answer, however. GLATTON.

[96784.]—**Grate Front** (U.Q.)—Why not cast the wrought-iron rods in the cast-iron bars? Must they be loose? GLATTON.

[96796.]—**Marine Condenser** (U.Q.)—Probably a bit of naval brass pipe running along close to where a bilge-keel could be fixed, and exposing about 2sq ft. of surface to the sea would answer—3ft. would, of course, be better. The exhaust should enter one end (preferably the after end), and a small pump will be required to extract the water and air from the other. Send an inquiry to Simpson, Strickland, and Co., of Dartmouth; they make these things. GLATTON.

[96970.]—**Reversing Arrangement for Oil-Engine.**—Probably the best way to reverse the shaft would be by means of friction-clutch and gear-wheels. There are many ways, however, by which this may be accomplished.
AUTO-CAR ENGINEER.

[97056.]—**Xylonite.**—The company making xylonite supply full details as to polishing it and fixing it on wood. It can be polished by rubbing with the usual chalk polish, and it can be affixed to anything with what is, I think, called acetone glue. The methods have been described in previous numbers, and, as mentioned, can be obtained from the company. M. T.

[97059.]—**Celluloid.**—See reply 97056, as the materials are much the same, and all necessary particulars can be found by searching the back volumes of this paper. M. T.

[97067.]—**Bluing Steel.**—Described many times. Only done properly by the temperature to which the articles are raised. The querist will probably obtain a reply from the correspondent he mentions; but if he cannot do the proper bluing, he can varnish his articles with a blue shellac varnish. T. P. L.

[97073.]—**Bleaching Horn.**—Can try peroxide of hydrogen or chloride of lime; but if can spare a little time, might look through the back volumes. Probably a quick bleach might be arranged with sulphurous acid; but, anyhow, the horns must be thoroughly clean beforehand. M. B. D.

[97090.]—**Salt-Water Ice.**—The sea ice is not salt. The salt remains in the water under the ice—at least, that is the fact. Why Arctic ice is "fresh" is another matter. It is a bit of a puzzle, as the querist says; but I understand it is true that the sea ice which forms in Arctic regions is practically free from salt. It is a question that has puzzled many, and, so far as I know, no satisfactory explanation has been given. M. T.

[97092]—**Cranberries.**—There is no difficulty in procuring cranberries. They can be had all the year round, as they come from America, Russia, and other parts of the world. Can nearly always be had in Covent Garden Market at about 5d. or 6d. a quart. Russian kegs about 2s. These prices are wholesale, but the retailers' prices are very little more. The answer to the query is that cranberries can always be obtained by those who want them. They are never "out of season." M. T.

[97235.]—**Melting Brass.**—Attach to tue-iron a piece of 1in. gas-barrel with angle-piece at end to point blast upward. Round it build, with loose bricks, a temporary stove, square in form, and about 18in. or so across. Light fire with a few shavings and bits of coal, and fill up between the bricks with coke. A small plumbago crucible holding about 3lb., and costing something under a shilling, should be bedded in the top of the coke. Hard coke is the best to use. A gentle blast at first, increasing as the mass reaches incandescence;—will melt brass in about 30 minutes. Nothing need be mixed with the brass, but if in lumps it could be cut up small with a hack-saw or chisel to save time in the melting. CLARA.

[97187.]—**Calculation of Sun's True Bearing and Altitude.**—May I point out to "Fleur-de-Lys" that I described the method of calculating the sun's hour-angle in a letter on p. 402 ("E. M." of June 16), where I made use of the formula generally used? In the "E. M." of following week there were letters signed D. J. Carnegie and "H.," in which other formulæ were given. To find the time of sunrise or sunset is to find the time at which the sun's alt. is *minus* 35′; therefore, if in any of the formulæ for hour-angle we put alt. = − 35′, it will give us the apparent time of sunset, or, by subtracting from 12h. of sunrise. The triangle "Fleur-de-Lys" mentions is not properly a spherical triangle at all, as the side X A (sun's path in the sky) would not be a great circle except at the equinoxes. The triangle used in all these calculations is that formed by zenith, pole, and sun (Z P S), in which Z P is co-latitude, P S polar dist. (co-declination), Z S zenith dist. (co-altitude), angle P the hour-angle, angle Z the azimuth (measured from north). To find the sun's azimuth or altitude we must know the latitude, declination, and apparent time (or hour-angle). For azimuth, compute A and B from these formulæ—

$$\tan. A = \sec. \tfrac{1}{2}(PS+ZP).\cos. \tfrac{1}{2}(PS-ZP).\cot. \tfrac{1}{2}P,$$
$$\tan. B = \operatorname{cosec}. \tfrac{1}{2}(PS+ZP).\sin. \tfrac{1}{2}(PS-ZP).\cot. \tfrac{1}{2}P.$$

Then $180° - (A + B)$ is azimuth when P S is greater than Z P,

$180° - (A - B)$ is azimuth when P S is less than Z P,

estimated from the south in N. latitude. For altitude, compute α from the formula $\cot. \alpha = \tan. ZP \cos. P$. Then $\sin. (\text{alt.}) = \dfrac{\cos. ZP \sin. (\alpha + SP)}{\sin. \alpha}$.
ARCTURUS.

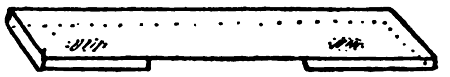
[97246]—**Air Heating.**—To obtain the amount of radiating surface required for a given room to compensate for heat lost by radiation from windows, doors, and walls, take difference in temperature in degrees Fahr. between lowest outside temperature to be provided for and the temperature at which the room is to be kept, and divide by the difference in degrees Fahr. between temperature of steam-pipes and the temperature at which room is to be kept. Multiply quotient thus obtained by number of square feet of glass thus obtained plus number of square yards of external wall surface in room, and product will be number of square feet of radiating surface required. Suppose a room with 36sq.ft. of window glass and 20sq.ft. of external wall surface to be kept at 70° Fahr. external temperature, being 10° below zero, that it is to be heated by direct radiators with low-pressure steam, taken as with a temperature of 210° Fahr. Then $\frac{80}{140} \times 56 = 32$ft. or number of square feet of radiating surface required. To provide for leakage from cracks, a square yard or 9sq.ft. of wall is reckoned as equal to 7sq.ft. of glass. If zero Fahr. be taken as lowest temperature, ¼sq.ft. of radiating surface at 210° Fahr. is required for each square foot of glass or square yard of external wall. Internal walls not included in calculation, it being assumed they are next to heated rooms or halls. If not, reckon as external walls. Having amount of radiating surface to compensate for loss of heat through windows and walls, next calculate the amount of radiating surface needed to heat cold air coming into room. Rough formula is: Multiply number of cubic feet of air per hour by number of degrees Fahr. to be heated, and divide by 12,500. Quotient equal number of square feet of radiating surface required. Suppose cubic contents of room to be 1,700c.ft., that it is on side of building exposed to winter winds, that usual amount of leakage around windows and doors exist; then an amount equal to that contained in room will probably pass through it per hour. And $\frac{1{,}700 \times 80}{12{,}500} = 11$, nearly, which, added to 32, gives 43sq.ft. as amount of radiation surface required, or equivalent to adding ⅓ to radiating surface for leakage, or 1sq.ft. radiating surface for 40c.ft. of space. Suppose ventilation of 6,000c.ft. per hour or over, three times per hour for two persons. Then $\frac{6{,}000 \times 80}{12{,}500} = 38{\cdot}4$, which, added to 32, gives, in round numbers, 70sq.ft. of required radiating surface. Suppose a 24-bed ward in brick hospital, where temperature of 20° Fahr. below zero is to be provided for; the internal temperature to be 70° Fahr. Assume this ward contains 24,000c.ft., has 288sq.ft. of window surface, and 241sq.yd. of external wall surface; and that, under ordinary circumstances, supply of air to be 3,600c.ft. per bed per hour, or 86,400c.ft. of air per hour. To supply loss of heat through walls and windows, there will be $\frac{90}{140} \times (288 + 241) = 0{\cdot}643 \times 529 = 340$sq.ft. of radiating surface. To heat 86,400c.ft. of air from 20° Fahr. to 70° Fahr. would require $\frac{86{,}400 \times 90}{12{,}500}$ = 622sq.ft. of radiating surface. Theoretically, 340 + 622 = 962sq.ft. of radiating surface required to keep ward thoroughly heated and ventilated in coldest weather, or at rate of 1sq.ft. of radiating surface to 26c.ft. of space heated.
REGENT'S PARK.

[97256]—**Windmills.**—In my reply on p. 431 I omitted to say that *h* is measured in inches.
GLATTON.

[97257.]—**Coherer.**—The latest and best form is one consisting of a number of short metallic tubes, ¾in. long, $\frac{3}{16}$in. bore, fitted with metallic bottoms and ebonite caps. These are furnished with wire stalks of different lengths, attached to the metal bottoms. Similar wires pass through the ebonite caps, reaching nearly to the bottom of the tubes. The tubes are then half-filled with antimony filings of different grades of fineness, the coarsest being put in those with the shortest wires, and the finest in those with the longest. These tubes are then mounted, like the strings of a harp, between a triangular metal frame, made in two halves, and united at its apex and at the centre of its base by insulating strips of ebonite. This is our "multilocular polytonic coherer," patent applied for, and is exquisitely sensitive. You cannot make a *small* alternator for this purpose. You had better use an 18in. plate Wimshurst in connection with a Tesla coil. The Wenbelt break consists in a ¼in. tube of glass, drawn to a point at one extremity. This is broken off, and a short piece of No. 20 platinum wire inserted, so as to project ¼in., and reach ¼in. in the tube. It is then sealed in over a spirit-lamp. The other end of the tube, which should be about 4in. long, is opened out slightly in the shape of a funnel. Any suitable glass jar is now fitted with a slotted ebonite cover; a sheet of lead passes down one side of jar inside, the tube is let down in slot, the jar nearly filled with diluted sulphuric acid, and the tube half-filled with mercury.
S. BOTTONE.

[97267.]—**Marking Ink.**—Why not try solution of silver nitrate? Quill pen. Hot iron will make it turn black. I have not tried following, but they may suit:—(1.) Iron sulphate 1 drachm, linseed oil 1oz., vermilion ½oz.; grind perfectly smooth. (2.) Manganese sulph. 1 drachm, water 1 drachm, powdered sugar 2 drachms, lampblack ½ drachm. (3.) A solution of coal-tar in naphtha is largely used by bleachers to mark their goods.
CLARA.

[97275.]—**Smoky Chimney.**—"Amateur" may find the following plan, by which I have cured many a smoky chimney, effective. It is from a little book on smoky chimneys by the Rev. Prebendary Ainslie. A hole (or, if needful, two holes) of 5in. or 6in. diameter are made in the hearthstone in such a way as to communicate with the space below the flooring. They thus draw air through the ventilators, which are (or ought to be) in the walls, to supply air below the boards and prevent dry rot. At the fireplace the holes are covered with an iron plate, raised an inch from the hearthstone. This is closed on the three sides towards the room, but is open for two or three feet towards the fire.



The figure shows the shape as seen from the fireplace side. Of course, the dotted lines and holes are hidden by the plate. The plate is a little larger than the fender which stands on it. The holes supply air when the door is shut, and so cure the trouble without making the room cold. I don't think there is much chance of this failing; but the only alteration is so completely to build up the fireplace as to reduce the chimney all the way up to about the breadth of the grate. F. BENNETT.

[97276.]—**Boiler.**—A boiler has tenacity of about 31 tons and 58 tons per square inch in tensile and compression strength. Then there is a new alloy partiminium, used by motor makers in France, such as Dion and Bouton. The specific gravity is 2·89 cast, 3·09 wrought. Elongation varies from 5 to 8 per cent., and tensile strength from 45·500lb. to 52·600lb. per square inch. REGENT'S PARK.

[97280.]—**Steam Pressure in Locomotives.**—The North-Western and North-Eastern have 175lb. Probably others. REGENT'S PARK.

[97281.]—**Straight or Curly.**—I am not able to quote an example where the hair has been shaved, but can confirm Rose Thorn's statement in the case of loss by illness in the case of my brother, whose hair was wavy after an attack of typhoid fever, having been straight before. I believe straight hair is always circular in section, and curly hair elliptical or more or less flattened. It is difficult to see why the section should be altered by illness, but still more so by shaving. GLATTON.

[97284.]—**Geometrical Progression.**—"Ontario's" strictures come a little late. In attempting to assist correspondents we cannot be responsible either for the nature of their queries or the uses to which they can put the replies. If "Ontario" will turn to p. 189 (Oct. 6) he will find four answers to the question proposed, two only of which are strictly formal, although he selects mine alone for attack. Mr. Shaw and "C. P." each reduce the given pair of simultaneous equations to a resultant biquadratic, which happens to permit of further resolution into quadratic factors. Thus Mr. Shaw gives—

$$10r^4 - 21r^3 + 10r^2 - 21r + 10 = 0,$$

i.e., $$(5r^2 + 2r + 5)(2r^2 - 5r + 2) = 0,$$

or— $$(r^2 + \tfrac{2}{5}r + 1)(r^2 - \tfrac{5}{2}r + 1) = 0,$$

which give *four* values of *r*, two of which are rational. "C. P." in his elegant and recondite solution gives us—

$$\frac{r^2+1}{r} - \frac{r}{r^2+1} = \frac{62^2 + 1{,}364}{62^2 - 1{,}364} = \frac{5{,}208}{2{,}480} = \frac{21}{10}$$

or— $$r^4 - \tfrac{21}{10}r^3 + r^2 - \tfrac{21}{10}r + 1 = 0.$$

or— $$(r^2 - \tfrac{5}{2}r + 1)(r^2 + \tfrac{2}{5}r + 1) = 0, \text{ as above.}$$

But in all equations primarily of higher degree than the second we cannot be quite sure of reducing them to lower degrees, and, even when this can be done, it may be essential to resort to more or less arbitrary assumptions. As in Euclid, such assumptions are only justified by the conclusions to which they lead.

Algebra does not disallow assumption; it simply exacts rigidity in our employment of it, and reasoning therefrom. There was no "guessing" in the solution I obtained, because the assumption was justified by the result. "A. O. S.," in his neat solution, obtained the final equation $a + 20r = 42$, which is indeterminate, and only solvable by assumption. He reasoned thus:—"But a and r are integers, therefore $a = 2$ and $r = 2$." It is true r is certainly not necessarily an integer, although this supposition leads to a correct solution, and for that reason is admissible. Athough I do not propose to solve "Ontario's" present question, yet I may state that the two simultaneous equations he gives reduce to a quintic in x, which, therefore, admits of five solutions. This cannot be reduced to a quadratic, for even mathematicians cannot perform the impossible. I would remark, however, that if r be assumed to be an integer—which is quite permissible—then "Ontario" is justified in concluding that if—

$$\frac{315 - x}{150 + x} = r = 2 + \frac{15 - 3x}{150 + x}$$

Then r is necessarily 2, and the remainder 0, hence the numerator must vanish, and, therefore, $15 - 3x = 0$, or $x = 5$. This would be *one* of the five answers; but since r might also be ½, x would be 160, another solution. Perhaps I may be again reminded that "any little schoolboy" knows these things; but while we know that schoolboys are proverbially clever, this is no reason why a correspondent who asks for information should not be courteous to those who try to give it.

West Norwood. HENRY T. BURGESS.

[97282.]—**Automatic Feed.**—The "Fromentin Automatic Boiler Feeder" would seem to be just the thing that "J. A. C." wants. It will keep water level in boiler without constant attention. He will find full description on p. 100 of Salomon's "Electric Light Installations."

RICHARD HUDSON.

[97287.] — **Photography.** — Purchase 1oz. of Nelson's gelatine, soak in cold water for half an hour, take out and drain, place in a small tin saucepan, and hold over a small gas-burner or stove, stirring until thoroughly melted. While hot, brush this on back of sheets of photos., hang by clips on line to dry; when dry, cut as desired; lay on damp pad, and press on card. PHOTO.

[97287.]—**Photography.**—Powdered starch (at chemist's), best, or best Glenfield's, 1oz.; rub up into stiff cream with 1oz. of water. In clean white enamelled saucepan put 8½oz. water; bring to boil. Pour in the starch cream, constantly stirring; should form translucent jelly, lump free. Transfer to saucepan, just boiled, well strain through fine linen or old cambric handkerchief into jar, add ten drops of carbolic acid. Does not keep long, say a week; and Le Page's glue advised by E. J. Wall in "Everybody's Guide to Photography." This liquid glue mixed as required with equal quantity of water forms an excellent and cleanly mount.

REGENT'S PARK.

[97290.]—**Galvanometer.**—An ordinary post-office galvanometer has a fairly high resistance in the "intensity" coils, so that it could be used with fair accuracy for measuring E.M.F., provided this did not greatly exceed 5 volts. It would not even be necessary to alter the grading, as a table could be made in which the number of degrees of arc equivalent to 1, 2, 3, 4, or 5 volts were recorded. Of course, such an instrument could not be used in the vicinity of iron, steel, magnets, or dynamos. The comparative grading can be done either by coupling direct to 1, 2, 3, 4, and 5 Daniell cells, and noting the deflections with the "intensity" terminals in circuit, or by putting it in shunt with another voltmeter or source of electricity. But, of course, very great accuracy must not be expected, as the coils are probably copper, and not German silver or platinoid. S. BOTTONE.

[97298.]—**Cement.**—Glass and brass: Caustic soda 1, colophony 3, water 5; boil together. Knead up resin soap, formed with half its weight of gypsum. It hardens within three-quarters of an hour. If zinc-white or white-lead is used in place of gypsum, hardening is slower. Metal to glass: Copal varnish 10, drying oil 5, turpentine 3, oil of turpentine 2, liquefied glue made with least quantity of water, 5; melt together in water bath, add fresh slaked lime (perfectly dry) in very fine powder 10. Cement electrical: Black resin 7, red ochre 1, plaster of Paris ½ (both well dried and still warm), melted together, heat and agitation continued till all frothing ceases and liquid runs smooth: the vessel withdrawn from fire, mixture stirred till cool enough. Used to cement plates in galvanic troughs, chemical vessels, &c. REGENT'S PARK.

[97298.]—**Cement.**—1. Good "fine" plaster of Paris, to be mixed just before using, with a mixture of equal parts of water, white of egg, and one-eighth of freshly-slaked quicklime. 2. Burnt alum 1 part, plaster of Paris 8 parts, good vinegar, sufficient to make up a stiff cream. For the above recipes, the plaster must be of the finest quality, as used by the Italian modellers, and freshly baked; coarse, stale stuff is of no use. S. BOTTONE.

[97298.]—**Cement.**—Roughen your glass with No. 2 emery-cloth, get some good plaster of Paris and mix it up with glue-water or some of the stick-fast gums. Such things as I have stuck with the above I have had to smash out with a hammer, if the plaster is good. You must, of course, remove all grease. JACK OF ALL TRADES.

[97299.]—**Budding Roses.**—The Manetti rose is a rampant variety of the ordinary dog-rose, originally cultivated for budding purposes by an Italian of the name of Manetti. I have sometimes allowed a budded Manetti to throw up suckers from its own roots, just to see what its blooms were like. They are somewhat double, very pale in colour, and not possessing much scent. It is very doubtful whether they are really superior to a good Dog-rose stock for budding purposes. S. BOTTONE.

[97299.] — **Budding Roses.** — A genus Rose stock, much used for low plants. Frequently Teas are budded to them. But the Dog-rose is a favourite stock for most kinds, if budded at all. Many prefer on own roots. REGENT'S PARK.

[97299.]—**Budding Roses.**—Manettia (named after Xavier Manetti, Prefect of the Botanic Gardens at Florence in the middle of the eighteenth century), a genus of thirty species of very ornamental stove, evergreen, herbaceous, suffruticose, climber, natives of Tropical America and sub-Tropical Australia. Many are exceedingly useful for growing on trellis, rafter, or pillar.

161, Albion-road, N. A. CLARKE.

[97300.]—**Pretroleum v. Coal.**—Units of heat average of petroleum out of nine kinds about 11¼—i.e., crude oil—nearly three times as large as air-dry pine, 1·5 times as large as Moravian coal (with 8·28 per cent. ash); massive, about 1·5 times denser than crude oil. Both fuels occupy about same volume, but in consequence of communication coal requires more space (Braunt). Crude petroleum is more than twice as efficient as best anthracite coal. In practice 16lb. of water per pound of petroleum have been operated, and an efficiency of 20,200c. was obtained as against 8,603c. for anthracite. Coal gas for kilo coal gives about 0·3 cubic mètre gas or about 20 per cent of heating value, see A. H. Gill on gas and fuel analysis, 1896.

REGENT'S PARK.

[97303.]—**How to Solder.**—For hard soldering or brazing, meeting edges scraped or filed clean. Bind with iron wire if necessary. When pieces placed in position, granulated spelter and borax mixed in cup, very little water, and spread along joints by sheet-metal or small spoon. Work placed above clear fire first at small distance, gradually to evaporate moisture and deprive borax of its water of crystallisation. The flux boils frothy, and at times shifts solder away. Heat now increased, and when metal assumes faint red, borax melts. As metal becomes deeper red, solder flushes. Should it not do, the work may be tapped with tongs to make it move; care taken not to melt metal. Spelter solder made of equal parts of copper and zinc, and for brass and copper. For iron, meeting surfaces filed bright; smear with water and borax. Tie together, if necessary, with fine iron wire. Then wind round at joint with several coils fine brass wire, rubbing borax paste over them. Lay on fire, and put on blast. A small blue flame appears, soon reflecting over place, a sign that brass is melting and heat is dissipating zinc constituent of brass; the brass having melted and run into joint, job is done. Centesimal composition of various hard solders:—(1) Very refractory, 57·94 copper, 42·06 zinc, 5 tin, 1·20 lead; (2) very refractory, 58·33 copper, 41·67 zinc; (3) refractory, 50·00 copper, 50·00 zinc; (4) readily fuse, 33·34 copper, 66·66 zinc; (5) half white, 44·00 copper, 49·90 zinc, 3·30 tin; (6) white, 57·44 copper, 27·98 zinc, 14·58 tin; (7) malleable sol., 72·00 copper, 18·00 zinc, 4·0 tin; (8) hard sol., 53·30 copper, 46·70 zinc., &c. See Braunt—"Metal-Worker's Handybook."

REGENT'S PARK.

[97304.]—**Oxygen.** — Think not, as C.C. by water. Generally from metallic oxides, in usual way of retort over lamp with double-neck glass globe, and by bent tube under glass jar, lower end immersed in water trough. See books on chemistry.

REGENT'S PARK.

[97304.]—**Oxygen.**—Oxygen is easily obtained by adding cold water to dioxide of sodium $Na_2O_2 + H_2O = 2NaHO + O$. Aqueous solutions of ferrates give off oxygen when concentrated.

W. M.

[97305.]—**Small Milk Separator.**—No doubt most are made so. 2,000 revs. per minute may be fair; large ones—say, Alpha Laval—run 6 to 7,000 with 12 to 360gal. per hour. See Oliver on "Milk, Cheese, and Butter," or inspect Dairy Supply Co.'s and other dealers' makes. REGENT'S PARK.

[97307.]—**Fireclay.**—Get some good fireclay—granite, if possible, what they use for crucibles, and at Sheffield, &c., in furnaces, mix with water to a proper consistency, workable without dropping, lay on with trowel, wetting the place first, and leave to dry for several days before use. You may, in some ironmongers, get fired clay blocks ready to insert. The expense of either would not be great. Should you fancy using petrifite plaster at about 6s. or more the bushel, I think, at depot, Orchard-yard, Blackwall, E., that stands a great heat is very adhesive, to anything and dries adamantine in hardness. REGENT'S PARK.

[97307.]—**Fireclay.**—Take the finest ashes from under your grate, and mix about two parts in bulk to one of good fireclay or pipeclay, well work it up with brine or water with about as much salt in it as it will take up cold, and fill up your odd corners with that. JACK OF ALL TRADES.

[97308.].—**Soda and Uric Acid.**—Bicarbonate of soda used in certain stewed fruit, say what will cover a shilling to each pound of fruit. Cane-sugar more prone to create acidity than milk-sugar. Digestible form of fat is cream and hot water equal parts, with 10 drops of sal-volatile to each fluid ounce. You can soon see whether you have uric acid by testing with litmus paper; the urine turns red. Probably arises from overfeeding. It is difficult to define diets for different ages and temperaments; habits, outdoor or indoor, each require modification.

REGENT'S PARK.

[97311.]—**Soluble Sodium Silicate.**—This is an ordinary glass, made of sand (silica) and soda, with so large an excess of soda as to render it soluble in water. The resulting solution, which is rather syrupy, has been used to render wood and textile fabrics uninflammable. It was employed by Von Fuchs in his stereochromatic wall-painting, also by Ransome in the preparation of artificial stone, and for preventing the destructive influence of the atmosphere on certain soft stones in public buildings—e.g., the House of Commons. Soluble sodium silicate, or "water-glass," may be prepared by fusing together 45 parts of silica, 23 parts of calcined soda, and 3 parts of charcoal.

S. BOTTONE.

[97311.]—**Soluble Sodium Silicate.**—Suppose you mean water-glass; if so, for protecting white colours in printing processes, for silicifying stones, for bleaching purposes, for finishing linen and cotton goods, binding and fixing medium for ground colours for cotton goods, for painting, for rough-casting walls, for painting metals and glass, for cements, &c. REGENTS PARK.

[97313.]—**Screw Propeller.**—If models of each other, the pitch of the small ones will be half that of the large one, so the speed will be considerably less. If the pitch is the same, the blade area of two propellers with ½in. blades will be less (about half) than that of the single propeller with the same number of similarly shaped blades 1in. long; so there will be more slip and less speed in this case also. GLATTON.

[97314.] — **Wimshurst Machine.**—To MR. BOTTONE.—An 18in. Wimshurst, with even one pair of ebonite plates, will light up a tube that no 6in. spark coil will touch. You will find full working directions for making such a machine in my book "Radiography," which you can see at almost any public library. In the new edition of "Electrical Instruments," which is now in the hands of the printers, I have dedicated a chapter specially to the construction of X-ray Wimshursts. Should you not be able to wait till that appears, and care to write to my address as below, I will post you a little pamphlet on the subject.

S. BOTTONE, Electrician.

Wallington, Surrey.

[97315.]—**Increasing the Power of a Steam Engine.** — Utter balderdash! It don't. This American joke (?) has not even the merit of being funny or plausible. GLATTON.

[97317.]—**Coaling Locomotives.**—If trucks of coal are shot in automatic self-acting hoppers and weighing machines to waggons or sacks below, as done for years at Midland Coal Depot, St. Pancras-road, by the invention of a deceased member of Parliament, the introducer, and persistent advocate, in or out the House, of the load line mark for ships. I see no reason why something of the sort should not be done for loco. tenders by having a movable sloping floor between axles of waggon, and lifting trucks by hydraulic pressure is rampant nowadays, and thus shooting out the five tons usual.

REGENT'S PARK.

THE Board of Trade have informed Mr. J. E. Ellis, M.P., who has taken an interest in the question of the date of issue of railway companies' time-tables, that in future time-tables will be issued five days clear before they are to come into operation. The Railway Companies' Association have, within the last few weeks, informed the Board that this arrangement has been made as the result of the meetings held by the general managers of the various railway companies to consider the matter.

UNANSWERED QUERIES.

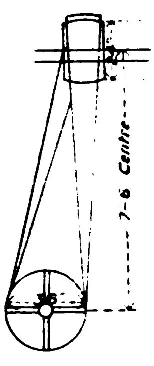
The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered, are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.

Since our last, "Glatton" has replied to 96727, 96740, 96751, 96779, 96784, 96796.

QUERIES.

[97318.]—**To "Jack of All Trades."**—I am sorry I am not able to comprehend the information you kindly gave on screw gear-wheels, although I have looked at number you refer to. I cannot understand how to use and where to fix the angle-plates. Also how to use the tool and where to fix for cutting, although I am used to a lathe—yet it seems a mystery.—J. A. C.

[97319.]—**Belt.**—Will "Monty" or some other reader kindly advise me as to the following? I have a 6in. belt on a quarter twist (as per sketch inclosed). Ordinary leather



belts only last a very short time, owing to the great strain and such short centres—only 7ft. 6in. I thought of trying rope-driving, but am told that ropes would be no good on such small pulleys, and I have only room to enlarge them 6in. Will someone kindly tell me what would be best. About 12H.P. Also, could anyone give me the name of a good book on carding machines?—W. MOORE.

[97320.]—**French Black Stain.**—Can any kind reader oblige me by giving correct recipe for above? I have tried numerous experiments from books, but each one will not penetrate into the hard woods (such as oak and birch) sufficiently deep to stand thoroughly glass-papering.—T. DYSON.

[97321.]—**Oxyhydrogen Blowpipe.**—Will any reader kindly give me the full information regarding the making of an oxyhydrogen blowpipe, also that it may be used for limelight? What is the best method of preparing the gas (oxygen and hydrogen) under pressure? What will be the cost of a platinum burner for same? Is there any danger in the use of this gas?—R. M.

[97322.]—**Cement for Rubber.**—I have a long cut in the rubber of the outer cover of my bicycle tire. Ordinary rubber solution will not hold the cut together. Can you tell me how I can make something suitable for the job?—HAROLD WATKIN.

[97323.]—**Dynamo.**—I have a dynamo which I cannot get to work. Would any electrical readers kindly tell me the cause, &c.? Field-magnets, 2in. long by $\frac{3}{4}$in., thick, wound with No. 22 B.W.G. in the form of ∾, the two ends joined together, and the two beginnings connect, on to brushes. The armature wound with No. 20 B.W.G., and the ends connect on to two-part commutator Siemens armature. Slits in the commutator face slits, in armature, the dynamo is of under-type, and brushes are set in upright position. The dynamo is magnetised. Kindly state the cause of not working. I cannot get the slightest deflection with a galvanometer. I have also tested for leakage.—MUNROE.

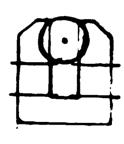
[97324.]—**Gas-Engine.**—Will readers who have had considerable experience in gas-engines kindly answer me the following in as simple a way as possible? I have a $\frac{1}{4}$H.P. gas-engine, which has been working well up to this last week; but since then, for some unaccountable reason, it has suddenly stopped, and, try my best, I cannot get same to work. I had a new crank put in lately, and this crank has a $\frac{1}{16}$in. longer throw than the old one. I have had both valves out and cleaned. When trying to start, and after revolving fly wheel for about thirty times or revolutions, I get a tremendous explosion, which almost takes the engine off its bed. Just before engine stopped working altogether, the exhaust, instead of making the usual noise, used to go off like a gun. Ought the spring on the inlet valve to be stiffened, and is the exhaust working quick enough? I should feel greatly obliged if any reader would give me a full explanation as to the cause of this bad working of the engine?—MOUSETRAP.

[97325.]—**Wireless Telephone.**—To MR. BOTTONE.—Many thanks for reply to query "Wireless Telegraph." Now, would you kindly inform me concerning the above? I want to make a wireless telephone to work for about a mile. How is it arranged? Is an induction coil and coherer used, and, if so, how? I understand that an ordinary telephone receiver and transmitter are used. A sketch would greatly oblige, giving dimensions.—F. C. CHASE.

[97326.]—**To Mr. Bottone.**—I have made a sort of musical-box arrangement for simultaneously striking, with ordinary electric-bell strikers, three sets of hand-bells, of eight bells each, which are to be placed in different parts of a large house. What will be the best way of arranging these—in series or in parallel? Any information will be gratefully received.—R. M. G.

[97327.]—**Sparking Coil.**—Will any kind reader tell me how to make a sparking coil for motor-tricycle, or refer me to a good work on the subject?—STYL.

[97328.]—**Small Dynamo.**—To MR. H. HUMPHRIES.—I wish to make a small dynamo of the type shown in sketch, and it must have either a ring or drum armature.



The output required at 3,000 revs. is 1 or 2 amps. at six-volt. pressure. Please say what size to make it, and what quantity of wire to use? I wish to keep to the proportions of sketch, so as to have the armature low.—F. C. CHASE.

[97329.]—**Electrical Contact for Regulator.**—Will some kind reader please tell me how to make and fix an electrical contact to an eight-day regulator with seconds pendulum to operate an electro-magnet, the armature of which is to work with a wheel having 60 teeth, so that at each swing of the regulator pendulum the magnet shall attract the armature and by so doing shall cause the wheel to make a revolution in one minute, and this wheel to work others for minutes and hours. Sketch would oblige.—NOVICE.

[97330.]—**Steel-facing Copper Plates.**—I beg to thank Mr. Bottone for his reply (p. 410) to my question No. 97210, p. 388, but must confess I had hoped to receive fuller information. He seems to have supposed that all I required to know was whether my series-wound Gramme dynamo could be used for this work, whereas I was, and am, quite prepared to employ a more suitable machine if he had suggested one, after having given his reasons why the said machine is unsuitable. In part (2) of this query I asked how to regulate intensity of current with varying surface of copper in vat, and instruction for constructing a variable resistance if needed. In part (3), what is the best solution to employ, having experienced little success in preliminary experiments? All this Mr. Bottone appears to have overlooked, unless his answer is "to procure Bonney's 'Handbook on Electro-Plating'" (which I have written for). Hitherto I have carried out my experiments based on the contents of Watts' "Electro-Deposition," but regret that this book does not give sufficient details of plating plant by current from dynamo. Moreover, this being a relatively little-practised process, the information is necessarily scant. I shall be extremely obliged to any reader who has had experience in this class of work for a sketch of plant, best voltage, number of ampères for given surface of copper, recipe of solution, and any other hints he may be disposed to give me.—TRINACRIA.

[97331.]—**Dynamo Coils.**—Could any reader kindly tell me the reason the coils of a shunt-wound dynamo heat after a few minutes' running? Would putting a resistance in shunt make the lamps glow more brilliant and stop the heating, or does it want more than four lamps in circuit for a 50 volt 4amp. dynamo?—PERPLEXED.

[97332.]—**Electric Ignition Coil for Motor Car.**—Will Mr. Allsop or Mr. Bottone please furnish me with particulars for making coil to be worked from four dry batteries?—viz: (1) length and diameter of iron core; (2) number of turns and gauge of primary wire; (3) weight of secondary wire and thickness of same; (4) is it essential that the secondary should be wound in several sections?—F. W. BERNARD.

[97333.]—**Spring Pressure.**—I want to work the downward thrust of a pump by means of an open spiral spring, so as to get pressure of 40lb. to the square inch. Size of plunger is $\frac{3}{8}$in. diameter, cylindrical. What pressure of spring should I use?—B. E. S.

[97334.]—**Spiral Barrels.**—To "J. H."—It is some time ago that I wrote to the "E. M." asking how spiral barrels were made. I was very pleased on opening the "E. M." of Dec. 22 to find such valuable information on the subject. I wish to thank "J. H." for the same, and ask if he can give information on making the larger barrels in loam?—ROBT. CRAWFORD.

[97335.]—**Dandruff.**—Among the innumerable preparations advertised for allaying and preventing scurf or dandruff, only one out of all I have tried has anything like the desired effect, but the price of latter is so high that its continued use means a very big item. I would be glad, therefore, if any of "ours" will suggest the probable ingredients employed in the preparation referred to (it appears like lard, and when rubbed on the hands or head shows traces of some white gritty powder), as I am certain it would prove a boon to many thousands of your readers besides—ME.

[97336.]—**Roller Bearings.**—On p. 174, "J. H." mentions some trials with roller bearings on tramway cars, which proved an advantage in their usage. Would not roller bearings be useful on ordinary carts, cabs, &c., and what is the reason they are not employed on locomotives, traction engines, &c.? Is there any mechanical difficulty? The opinions of your readers on this matter would be welcomed, for if roller bearings are useful on road-cars, why not on locomotives?—ROTA.

[97337.]—**New Form of Microscope.**—Can any reader explain this new form of microscope, thus described? According to *Technische Notizen*, the celebrated Parisian oculist, Dr. Emil Berger, has constructed a binocular microscope which admits of seeing objects plastically—i.e., in relief. As is well known, the stereoscopic effect is lost by the use of only one eye, and consequently of our monocular microscope, not to speak of the harmful suppression of the vision on one eye at the expense of the other. This new microscope places the object in a normal distance (about 33 centimètres) from the eye.—MYOPS.

[97338.]—**Motor Tricycle.**—To "THE WRITER OF THE ARTICLES" OR "MONTY."—Will either of the above gentlemen say if they know any two-speed gear suitable for the Di Dion tricycle, preferably one that can be thrown in and out of action while engine is running? By this, I mean that if I am compelled to stop tricycle when going up a stiff hill, I wish to leave engine running so as to avoid doing the treadmill business before I can again start on my journey.—F. W. B.

[97339.]—**Accumulator.**—Will Mr. Bottone or any other reader kindly tell me how I can charge a four-volt pocket accumulator with a dynamo giving 50 volts 4amp.? Kindly state the resistance required, and position of resistance, if any? A sketch would greatly oblige.—PERPLEXED.

[97340.]—**Oil-Engines.**—Could "Ignition Tube," or any other reader having had experience, kindly tell me the cost of running per hour with a $\frac{3}{4}$B.H.P. engine, also starting and driving; and is the knocking in cylinder caused by not having sufficient oil with mixture? The engine I refer to is one of Barker's $\frac{3}{4}$B.H.P. oil-engines, running at 350 revs. per minute.—W. P.

[97341.]—**Small Dynamo.**—Could Mr. Bottone kindly tell me a simple way I could wind an eight-cogged drum armature 3in. long by $1\frac{1}{4}$in. diameter, spaces for winding $\frac{3}{8}$in. wide by $\frac{1}{4}$in. deep, for a 20 volt 3 to 4 amp. dynamo? Would No. 22s.c.c. wire be suitable for winding F.M. and armature, as I should like to obtain the best result possible? Kindly state size and weight required.—PERPLEXED.

USEFUL AND SCIENTIFIC NOTES.

A NEW type of wheel for traction engines has been invented in America. Surrounding the hub of the wheel is a ring carrying rollers which bear upon the bottom of a groove formed in the hub. Arms pivoted to lugs on the outer side of the ring extend outward tangentially to the ring, and carry at their free end blades which project through openings in the rim, and which adapt themselves to the nature of the ground. Springs are connected at their inner ends to the ring, and are adjustably secured at their outer ends to brackets on the rim. Should the wheel travel over hard ground, the blades, as they engage the ground, will be forced inward, causing the ring to rotate on its bearing rollers. Upon reaching soft ground the blades will be moved outward by means of the springs, acting upon the ring, so that they will engage in the ground.

Electric Locomotive for the Jungfrau.—The electric locomotive constructed by Brown, Boveri Co., destined for the Jungfrau Mountain Railway, is said to be the most powerful rack-wheel machine hitherto constructed, and is designed to haul trains over the steepest portion of the road. The motors are placed under the passenger cars, whereby greater adhesion between the driving-wheels and rails is obtained. The car truck is provided with two bearing-axles and two driving-wheels, the latter being situated between the former. Two motors, each of 125H.P. at 800 revolutions per minute, actuate the toothed wheels through the medium of duplicate gearing. If required, these motors are capable of working up to 300H.P. The driving current is conveyed overhead at a tension of 500 volts. The pivots of the toothed wheels are of aluminium-bronze, the teeth being of cast steel.—*Feilden's Magazine.*

Belgian Artificial Stone.—An artificial stone from Belgium has recently been introduced into the French market, which is said to have four times the force of resistance of French freestone, and which has nearly all the properties of Cobestang granite. Consul Atwell, of Roubaix, states that it has been tried in the Malines Arsenal, and is found to be insensible to the action of cold, absorbs only 6 to 7 per cent. of water, even after a long dry spell, and cannot be crushed under a pressure of 40 kilogrammes (88lb.) to the square centimètre (square centimètre = ·155 square inch). This artificial stone is manufactured at Uccles, near Brussels, in the following manner:—Eighty parts of extremely clean and dry coarse sand are mixed with 50 parts of hydraulic lime reduced to a fine dry dust; this mixture is put into an iron box, which is plunged into a boiler of water, and this is hermetically closed. During 72 hours the cooking goes on under a pressure of six atmospheres, the temperature being maintained at 165°. At the end of this time, the iron box contains a perfect homogeneous mass of stone, which rapidly hardens upon exposure to the air. The most varied colours are given to this stone, and its manufacture costs only one penny per cubic foot.

ANSWERS TO CORRESPONDENTS.

⁂ *All communications should be addressed to the* Editor *of the* English Mechanic, 332, *Strand, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries, put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

⁂ Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such iinformation, and we trust our readers will avail themselves of it.

The following are the initials, &c., of letters to hand up to Wednesday evening, Dec. 27, and unacknowledged elsewhere:—

S. R. Bottone.—T. G. Challis.—W. Murdoch.—W. M.—Rev. A. C. Allen.—S. R., Bromsgrove.—James Paris.—William Godden.—Comus.—E. L. Garbett.—Ell Hay.—Jack of All Trades.—O'Dermid W. Lawlor.—A. Stammwitz.—Richard Inwards.

I. F. H. Gregg.—Thanks; but your account comes too late. A fortnight or three weeks ago we should have been g'ad of it.

W. H. S. Monck.—Too late for this week, and will be still later next.

W. H. Skelton.—Glad to see you any time. Have posted another copy.

C. G. S.—M.—Too vague and too vast for us to discuss. You must remember it is only the educated minority that are alive to the healthier influences you mention. The majority are still dominated by superstition and empiricism. Take the average doctor—he is as much a creature of rule of thumb as his forbears of five thousand years ago! The race has to live all this out; that is the only hope.

R. C. Gilson.—Probably the roller you have is one of the indiarubber or improved forms. The purpose for which the "inking rollers" are required is not stated. Some of those used in ordinary printing are made of glue and treacle—others have glycerine added with a little bichromate of potash solution to make them insoluble after exposure to light.

John Bowden.—All information of the kind required can be obtained from the secretaries of the institutions. In the special case, probably the "qualifications" amount to *nil*.

F. A. M.—Doubtful if there is such a work published. Electricity is a "wide" subject now, and although there are manuals giving practical directions for making apparatus, they cannot cover the whole field. You will find much information as to special points in back volumes; but "showing how to make the apparatus" is the point. Several useful works are advertised in our columns.

L. W. Hutchings.—Thanks; but we cannot spare the space just now.

The world's loss of sailing vessels during the first half of this year amounted to 92 ships, of 51,191 tons; of this number the United Kingdom supplied ten, of 9,109 tons.

The application of power-brake and automatic couplings in the United States, according to the latest report of the Interstate Commerce Commission, stands as follows:—Out of a total of 9,956 passenger locomotives, 9,845 are fitted with train brake apparatus; and out of a total of 33,595 passenger cars, 33,149 were so equipped at the end of June, 1898. Of the passenger locomotives, 5,105 had automatic coupling, and 32,697 passenger cars were thus equipped. In freight service 19,414 out of a total of 20,627 locomotives had train brakes and 6,229 had automatic couplings. Out of 1,248,826 freight cars, 567,409 had train brakes and 851,533 had automatic couplings.

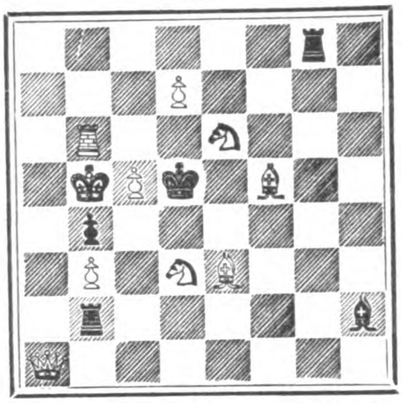
Night - Blindness.—Night - blindness, called also nyctalopia or hemeralopia, is a functional disorder of the visual acuity causing great inconvenience, and often producing a state of mental panic in the unfortunate person who is suddenly affected by it. An individual still retaining his normal acuity of vision in the daylight suddenly notices that his sight has failed when twilight comes on. It is caused by exposure of the eyes to a very bright light, such as a Tropical sun reflected off the dazzling surface of the Tropical ocean. Soldiers affected have been campaigning or on long marches exposed to the glare of the sunshine, and liable to find rations run short, and to be bereft of their usual and necessary amount of sleep, so that their vitality becomes lowered. This also accounts for the cases recorded accompanying attacks of scurvy.—*Hospital.*

CHESS.

All communications for this column to be addressed to The Chess Editor, at the Office, 332, Strand.

PROBLEM No. 1706.—By J. Graves.

Black. [5 pieces.



White. [10 pieces.

White to play and mate in two moves.

(Solutions should reach us not later than Jan. 8, 1900.)

Solution of Problem No. 1705.—By L. Hawkins.

Key-move, B-K 2.

NOTICES TO CORRESPONDENTS.

Problem No. 1705.—Correct solution has been received from Richard Inwards, T. Clark, Rev. Dr. Quilter, A. Tupman, Whin-Hurst, F. B. (Oldham), Quizco, Jas. Mason, Will Barton.

T. C. (Barnet), Frank Gowing, H. B. F.—Only solution, as above.

ADVERTISEMENT CHARGES.

The Charge for Advertisements in the Columns headed:—

For Exchange.
For Sale.
Wanted.
Addresses.
Situations.

is Sixpence for the first Sixteen Words, and Sixpence for every succeeding Eight or part of Eight, which must be prepaid. *No* reduction on repeated insertions. Advertisers should state under which heading they wish their announcements to appear.

The address is included as part of the Advertisement and charged for. No displayed Advertisements can appear in above columns. Rates for Displayed Advertisements are as follows:—

For advertisements on inside pages, except page facing leader, for less than a quarter-page; per inch single column—

1	6	13	26	52 insertions
7s. 0d.	6s. 6d.	6s. 0d.	5s. 6d.	5s. 0d. each.

Per Column.—

Quarter-page	2 10	2 5	2 0	1 15	1 10 ,,

Back Page, £10 10s. A few dates open during 1899.

ORDINARY ADVERTISEMENTS.

	£ s.
Thirty Words	2 6
Every Additional Eight Words	0 6

Front Page, Five Shillings for the first 40 words, afterwards 9d. per line. Displayed Advertisements, 10s. 6d. per inch. Paragraph Advertisements, One Shilling per line. No Front Page or Paragraph Advertisement inserted for less than Five Shillings.

All Advertisements must be prepaid, and in cases where the amount sent exceeds One Shilling, the Publisher would be grateful if a P.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.'s.

Advertisements *must* reach the Office by 1 p.m. on Wednesday to insure insertion in the following Friday's number.

For the convenience of advertisers, replies to advertisements (except those in the Exchange and Sale Columns) may be addressed to "——," care of the English Mechanic Office, and will be forwarded by post to the advertiser, for an extra fee of Sixpence per insertion over and above the cost of the advertisement.

All Cheques and Post-Office Orders to be made payable to The Strand Newspaper Company, Limited, and all communications respecting Advertisements should be distinctly addressed to:—

THE PUBLISHER,
THE "ENGLISH MECHANIC,"
332, STRAND, LONDON, W.C.

This is necessary, as there are several papers published at the same address, and unless letters are fully directed, it is impossible to tell for which paper they are intended.

NOTICE TO SUBSCRIBERS.

Home Subscribers receiving their copies direct from the Office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a Pink Wrapper, as an intimation that a fresh remittance is necessary if it is desired to continue their subscription.

Foreign Subscribers will have the Pink Wrapper sent One Month before expiration, in order to give them time to forward fresh remittance before subscription expires.

SPECIAL OFFER.—CHEAP VOLUMES.

In the course of the next few months we are compelled, owing to the making of the new street from Holborn to the Strand by the London County Council, to remove our Offices and Printing Works. Due notice of our removal will be given shortly. In the mean time, to reduce stock and save trouble of removal, we offer readers desirous of making up sets of back volumes *any volume* in the list below at half price, or post free for 4s. 1d.

Any reader desirous of making a free library or working men's club a present of a few sets of volumes will find this a favourable opportunity. The offer is only available till our removal.

TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

5s. 6d. for Six Months and 11s. for Twelve Months, post free to any part of the United Kingdom. For the United States, 13s., or 3dol. 25c. gold; to France or Belgium, 13s. or 16f. 50c.; to India, New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-Office Order. Back numbers can also be sent out by the ordinary newspaper post at the rate of 3d. each.

Vols. XXIV., XXX., XXXII., XXXVI., XXXIX., XL., XLII., XLIII., XLIV., XLV., XLVI., XLVIII., L., LI., LII., LIII., LIV., LV., LVI., LVII., LVIII., LIX., LX., LXI., LXII., LXIII., LXIV., LXV., LXVI., LXVII., and LXVIII., bound in cloth, 7s. each. Post free, 7s. 7d.

Indexes to Vol. LI., and to subsequent Vols., except Vols. LIII., LV., LVI., LVII., LIX., LXI., 3d. each, or post free 3½d. Cases for binding 1s. 6d. each.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each post free from the office (except xapu numbers, which are 3d. each, or post free 3½d.)

For Exchange.

The charge for Advertisements in this column is 6d. for the first 16 words, and 6d. every succeeding Eight, which must be prepaid.

Special Notice. — ***Correspondents are strongly recommended not to send money or goods to strangers. The safest way when dealing with unknown advertisers is to send a Post Office Order made payable —— days after date, when in case of non-arrival of goods, or dissatisfaction, payment can be stopped.***

Steam Launch, 27ft. multitubular boiler, 130 working pressure, fast, sell cheap, exchange Motor-Car.—Wheeman, Richmond.

3½ by 5 **Launch Engine**, complete, first-class article, £10, or exchange Gas-Engine.—Wheeman, Richmond.

Telescope. Calver 8½in., finder, eight eyepieces. Wanted, good light Brass-finisher's Lathe.—Banks, Corporation-street, Bolton.

Exchange good **Broadwood Piano** for lady's and gentleman's Bicycles, or good offer.—C. W. Searle, Sunning Hill.

Wanted, Gramophone Records. Exchange Echophone Phonograph, takes Edison's wax records, clockwork, with governors, in carrying box, value 20s.—James Sharp, High-street, Sanquhar, Dumfriesshire.

Organ, pipe, nearly finished, 339 pipes, two manuals and pedals. Exchange American Organ and cash to value, or offers. 363, Mile End-road, E.

For Sale.

The charge for Advertisements in this column is 6d. for the first 16 words, and 6d. every succeeding Eight, which must be prepaid.

New Illustrated Price List of **Screws, Bolts**, and Nuts for model work, drawn to actual size, sent on receipt of stamp.—Morris Cohen, 132, Kirkgate, Leeds.

Watch and Clock Tools and Materials. Catalogue, over 1,000 Illustrations, post free, 6d.—Morris Cohen, 132, Kirkgate, Leeds.

Wheel-cutting and Dividing in Brass or Iron to 12in. diameter.—Clegg, Belinda-street, Hunslet, Leeds.

Lathes and Machined Parts, Wheels, Chucks, Fans, Angle-plates. Illustrated list, 2d.—Jarratt, Queen-street, Leicester.

Eyesight.—All whose sight is in any way defective should send to Horne and Thornthwaite, 416, Strand, for—

"Hints on Spectacles" (Why the Eyes want Help), by Overstall, F.S.M.C. (with distinction), post free.—Above.

Rubber Outer Covers, 3s. 6d. Prepared Canvas, 90 by 9, 1s. 3d.; rubber solution, best quality, 1lb. tins, 1s. 6d.—Pemberton.

Air Tubes, all sizes, best quality, 2s. 9d. each. Air tubes with Dunlop valves fixed, 3s. 9d.—Pemberton.

Cushion Tires, 3s., 4s., 5s. Solid Tires, 3s. All sizes stocked.—Pemberton.

Detachable Outer Covers (Licensed), 12s. 6d. each; all cycle accessories and cycle rubber goods stocked.—Pemberton and Co., 1, Cardwell-place, Blackburn.

Nuts and Bolts for Model Work. Illustrated List, 2,800 varieties, 3d.—Butler Bros., Haggerston, London.

Screws, Screw-plates, Taps, round and hexagon special steel brass and iron rods. See list.—Butler.

Brass and Gunmetal Castings of finest quality. Prices on application.—Daniel Young, Witney, Oxfordshire.

"Acetylene: its Characteristics, Generation, and Use," with Descriptive Catalogue of "Incanto" Apparatus; just published, 2d. post free.—Thorn and Hoddle 1 Tothill-street, Westminster, S.W.

Simplex Typewriter, 14s. 6d., delivered. Thousands in use. Illustrated particulars free.—Atkinson and Co., Harehills-avenue, Leeds.

The English Mechanic
AND WORLD OF SCIENCE AND ART.

FRIDAY, JANUARY 5, 1900.

A SMALL MOTOR-CAR, AND HOW TO BUILD IT.—I.

IN introducing this design of motor-carriage to the readers of the ENGLISH MECHANIC, I would point out that there are no startling innovations; but I have endeavoured to make it as simple and cheap to build as is consistent with efficiency and strength. To this end, I have adopted the single-cylinder horizontal motor and belt transmission gear as the most simple arrangement. The use of belts makes a much more silent car than gearing; the starting is more gradual than with the usual friction-clutch as used with gear-wheels, and with quite a moderate amount of attention they will be found to work extremely well. As requested by several readers, my first article gives a general arrangement and description of the car, from which the disposition of the motor and gearing will be apparent. The car, as shown, is fitted with two speeds—one a slow or power gear, the second for use on level roads or when fairly fast travelling is required. The two belts give speeds of five and fourteen miles per hour respectively, any speed between or under these being obtained by regulating the engine. As will be seen later on, when treating of the belt gear, three, or even four, speeds forward and a reversing gear can be readily fitted, at the option of the builder.

Whilst fully recognising the desirability of having plenty of power, yet it must not be forgotten that a very powerful motor mounted in a light car gives rise to unpleasant vibrations, and tends to shake the carriage to pieces very rapidly. Therefore, for our carriage, which is intended to carry two persons only, I believe the happy medium will be a three-brake horse-power engine. As many of my readers may like to know the data on which the dimensions of the engine are based, I give them here. Bore of cylinder, 4in.; stroke, 5in.; compression, 50lb. per square inch above atmosphere—i.e., 65lb. per square inch absolute. Now it may be taken that the mean effective pressure in the cylinder is roughly 75lb. per square inch. The engine is designed for a normal speed of 700 revolutions per minute, and using the ordinary formula—

$$\frac{P \times L \times A \times E}{33,000},$$

where P = mean effective pressure in pounds per square inch.
L = length of stroke in feet.
A = area of cylinder in square inches.
E = number of explosions per minute.

we get— $\frac{75 \times \cdot 416 \times 12\cdot 56 \times 350}{33,000} = 4\cdot 17$ I.H P.

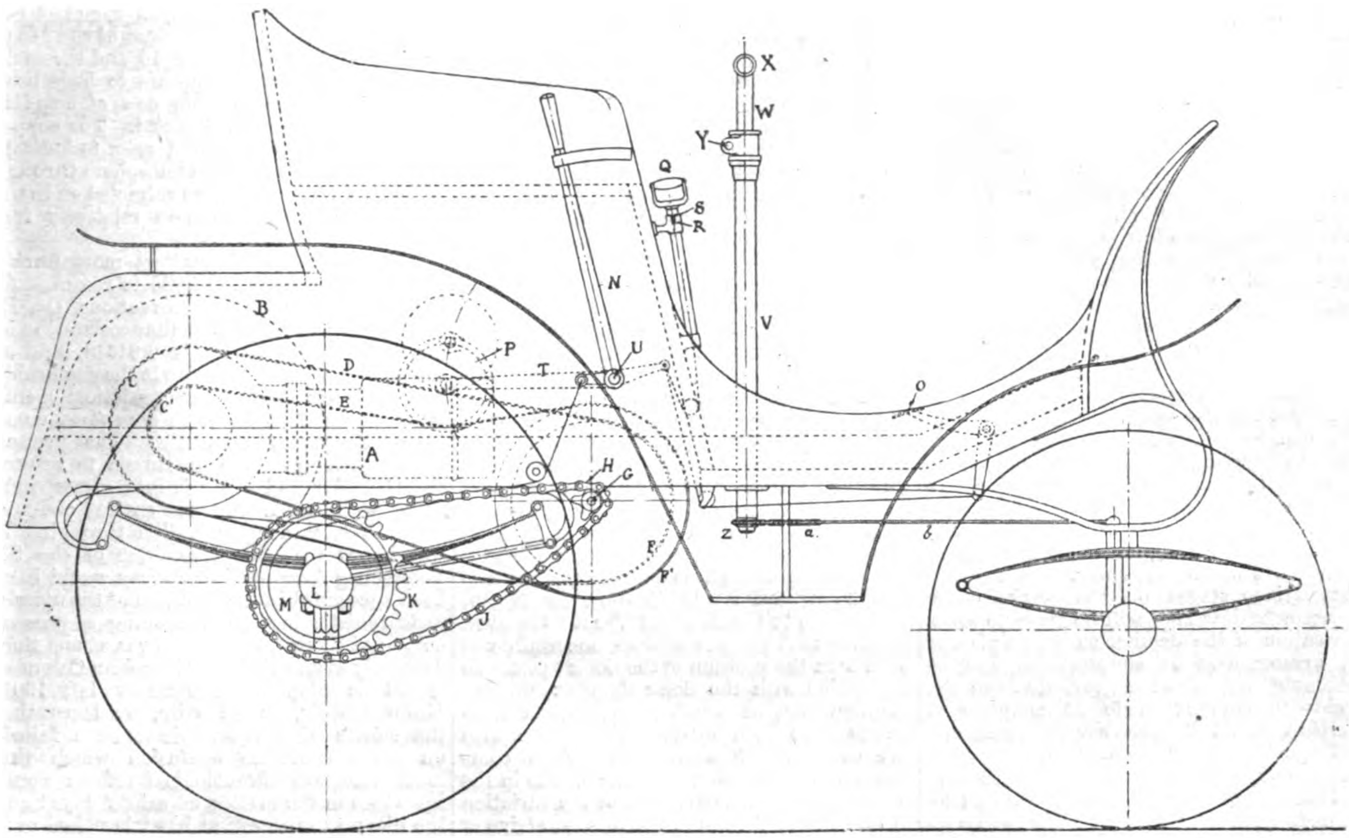
Allowing an efficiency of 75 per cent. makes it 3-brake horse-power. At times it would be possible to increase the speed of the engine slightly with a corresponding increase of power. This engine will be of ample power to propel a light car, such as I am about to describe, carrying two persons over any ordinary route where the gradients are not abnormal. A third passenger, if of light weight, or luggage, could be carried, but in this case the hill-climbing powers would suffer.

With regard to the cost of building the car, much depends on the upholstering and finish, and on the tires selected, whether pneumatic or solid rubber. Fig. 1 is a side elevation of the complete carriage, with the motor, &c., shown dotted. The reference for the letters is as follows:—

A is the motor, with its flywheel B placed horizontally in the rear of the car. On the crank-shaft are keyed the high-speed pulley C and low-speed pulley C'. These pulleys drive, by means of the belts D and E, the pulleys F and F' keyed on the countershaft G. This countershaft has a differential or balance-gear, and on the extremities are the spocket pinions H, one of which only is shown. A chain, J, connects each sprocket pinion with a larger sprocket-wheel K fastened to the road wheel-hubs L. Concentric with the sprocket-wheels are brake-drums M, encircled by brake-bands operated by the hand-lever N. Another band brake-drum is keyed on the countershaft, but not shown in Fig. 1. This brake is put into action by depressing the pedal O with the foot. When either brake is used, the engine is put out of gear with the countershaft in this manner. The belts normally run slack over their pulleys. The jockey-pulley P is arranged in such a manner that it can readily be brought vertically over either belt and depressed into contact with it. Hence the belt is tightened, and the car propelled at a slow or high speed, according to the belt in use. When, however, the brakes are used the jockey-pulley is raised, thus cutting off the power from the road wheels and allowing the motor to continue running although the car is stationary.

Change of speed is effected by means of the spade handle Q, which is first raised till the peg R is free of the slot S, this movement raising the jockey pulley, the handle is next rotated till the peg R is over the next slot, and this slides the lever T, carrying the jockey pulley laterally, along the shaft U (or rather along a sleeve on that shaft), when, the handle being released, the jockey pulley is lowered on to the other belt. The jockey pulley is kept down to its work by means of helical springs, not shown, which are adjustable so that the tension on the belts may be arranged to the best advantage. It will be observed that the connections from the brake lever, brake pedal, and speed-changing handle to the jockey pulley are made by means of flexible steel wire cords, which is a much cheaper method of construction than rods and bell-crank levers. Moreover, it allows of the various parts being arranged to suit the convenience of the driver much more readily than rigid rods and levers would do. The cords are always in tension, hence they may be used very easily.

V is the steering post, which has the steering-rod W carried on ball bearings within it, in the same way that a bicycle steering head is made, but stronger. At the top it is furnished with either a handle-bar X, or wheel, adjustable for height by the clip Y. At the lower end of the steering rod, below the footboard, is a small sprocket pinion Z. A short length of chain a, and



rods *b*, connect this pinion with the steering gear on the front axle. To start the motor I shall use a steel wire cord, connected to a clutch gear on the crank-shaft, the other end of the cord being attached to a handle within easy reach of the driver. The back of the car will be made to open to give access to the mechanism. The petrol will be carried in a tank below the seat where there will be room for about 4gal., sufficient for a run of from 60 to 70 miles over easy roads. The carburettor is of the surface type, the flow of petrol from the tank to carburettor being regulated by a float and valve of simple construction. At each side of the car are water tanks, the circulation of the water being natural; but I shall describe an addition in the form of a water cooler, though for this a pump will be necessary to insure circulation.

The ignition of the charges in the motor cylinder will be by electric spark, and the timing of the ignition will be regulated from the driver's seat. In addition to this there will be two other small levers, one of which is to be used to adjust the relative quantities of air and gas for the engine, the other being connected to a throttle valve. By manipulating this latter and the ignition gear, the speed and power of the engine can be regulated to a nicety.

The frame of the car can be made of various materials, either steel angle-bars, weldless steel tubing, or wood flitched with thin steel plates. For ease of construction the last mentioned will be the material selected for our car. If carefully made, this will be found in every way suitable, and though probably slightly heavier than steel tubing, yet the ease with which the various parts can be attached, combined with low cost and suitability for amateur work, renders this method of construction preferable. If desired, either of the other materials can be used. A little thought will indicate what alterations in the design of the various component parts will be necessary.

At various stages of the work, other arrangement drawings will be given to show the relation of the details, such as a plan of car, arrangement of countershaft and of front axle and steering gear, &c., and the articles throughout made as complete as possible to avoid the necessity for guesswork on the part of intending builders.

At the present time I do not think there is a belt-driven car which can be stopped by putting on the brake only. With those on the market, one has to first shift the belt on to a loose pulley or raise a jockey pulley before putting on the brake. Thus, two entirely separate movements are necessary, whereas with our arrangement it will be possible to drive the car amongst traffic and regulate the speed, stopping and restarting entirely by the foot, leaving the hands at liberty to steer, apply the second brake, or signal to drivers of other vehicles. The convenience of this when hemmed in by traffic is very great. It also allows of a sudden stop, in case of emergency, being made without the risk of forgetting to attend to the belt, which, if left "on," stops the engine as well as the car when the brake is applied. The pressure of the jockey pulley on the belts will be found to be much less than would appear at first sight: hence the wear and tear of the belts will be slight. To prevent slipping and breakage of the belts, I intend using them about double the width of those in use on cars of equal, or even slightly greater, power. There is one make of car of which a large number have been sold, which is 3½H.P. The belts in this car are 1¾in. wide, and to transmit the power they have to be tight, which rapidly wears out both belts and bearings. In our car I shall use belts 3in. wide, which will give a greatly-improved drive with much less tension.

In carrying out the design of our car, I have endeavoured, as far as possible, to rectify whatever my experience teaches me to have been defective or wanting in the majority of light motor vehicles at present on the market, at the same time bearing in mind the necessity for simplicity and low cost.

THE PROGRESS OF ASTRONOMY IN 1899.

VIEWED from an astronomical point of view, the penultimate year of the 19th century has proved by no means a sensational one. Probably the most interesting event which has occurred in it has—if we may be forgiven the Hibernicism—never happened at all. We refer, of course, to the shower of Leonids on Nov. 14-15, to which reference will be made in its proper place.

Of observation of, and fresh discoveries in connection with, the Sun, we have little or nothing to chronicle. The small partial Solar Eclipse which occurred during the early morning of June 8 was not seen at Greenwich, owing to cloud. The few observations of it which were published are quite destitute of interest. Another partial eclipse, which happened on Jan. 11, was only visible from inaccessible parts of the Pacific Ocean, while no reports of observations of the annular one of December 3 have reached this country from either West Australia or New Zealand at the time at which we write. As, however, it was merely the line of simple contact that passed through both these localities, it may easily be imagined that nothing whatever of the slightest scientific value is to be expected. Yet another determination of the direction and velocity of the Sun's motion in space has been attempted by Prof. Newcomb, with the result that he finds, by one selected set of stars, that we are travelling at the rate of some 18·64 miles per second (and by another at a speed of 10·25 miles per second!) towards a point whose Right Ascension is 18h. 30m., and its Declination 35° North, i.e., a little to the South of Vega. He adds, however that there is still an uncertainty of 3° or 4° in the position of the Solar apex. In connection with the Solar Parallax, we may mention that, as usual, observers and computers have been busying themselves with the constant of aberration. First come Messrs. Rees, Jacoby, and Davis, who in the course of their investigation of the variation of latitude at Columbia University, arrive at 20·461″ ± 0·006″ as the value of this constant. We next have Mr. Thackeray discussing the observations of Polaris made at Greenwich between the years 1836—1893, with a resulting constant of aberration of 20·49″; while finally, Herr Kniesche, of Göttingen University, employing the same observations, but in this case from 1851 to 1888, obtains a constant = 25·537″ ± 0·003″. Regarding the imminence of the Sunspot Minimum, a remarkable outburst occurred on the Solar disc on the morning of March 16th in a group which had appeared on the east limb of the Sun on the previous day. Another expiring effort took the form of a spot of considerable size, which persisted from June 23rd to its passage out of sight at the sun's western limb on July 6th. The area of this latter spot was estimated at some 500,000,000 square miles. Preparations for the observation of the Solar Eclipse of May 28th, 1900, are in active progress.

It can scarcely be legitimately said that any addition worthy of record has been made to our knowledge of the Moon during the year which has just ended. Prof. Very, as the result of an elaborate comparison of the radiation of heat from the Moon, and that from the surface of snow in full sunshine, found that the quality of the radiant heat emitted from the two sources was very different. A much greater percentage of the lunar rays was absorbed by a glass plate placed in front of the bolometer than it stopped from those reflected by the snow. It will be seen at once what grave doubt this throws upon the hypothesis of the late Mr. Peal, that the surface of the Moon was covered with, or made up of, ice and snow. The actual surface temperature of the Full Moon is estimated by Mr. Very to be something approaching to 206° Fahr., which is very near, indeed, to that of boiling water; while in the centre of the lunar disc, when the Sun is vertical, he believes that a temperature of about 324° Fahr. exists. On the other hand, Prof. Very supposes that the temperature of the Moon's night must fall to —360° Fahr.! With such tremendous alternation of temperature, it may well be that rocks are rent and shivered in all directions. We may perhaps mention here that MM. Lœwy and Puiseux continue to take their superb photographs of Lunar detail with the great equatorial coudé of the Paris Observatory. The Eclipse of the Moon on the night of December 16 and the early morning of the 17th appears to have been well observed, but nothing new of any importance to have been detected. The copper colour of the shadow would seem to indicate that that portion of our atmosphere through which the Sun's rays were refracted on to the Lunar disc must have been relatively free from cloud.

In connection with matters more purely terrestrial, we have but little to record. As the result of a series of observations, Dr. R. Schumann has found that the acceleration of gravity at Copenhagen is 9·81578, and at Christiania 9·81945. Owing to the deplorable war in South Africa, the geodesical operations at the Cape have, *ex necessitate*, come to a temporary standstill. The praiseworthy attempt made in Russia to reform the Calendar and bring it into correspondence with that of the entire civilised world has, unhappily, fallen through. It was hoped that the Committee of the St. Petersburg Astronomical Society would have been successful in the abolition of the utterly anachronistic mode of reckoning at present employed there. In fact, it was at one time definitely stated that the Gregorian Calendar would be adopted on January 1st, 1901. Unfortunately, as we write, we learn that the efforts of the committee have failed, on account of the confusion which this most necessary chronological reform would introduce in the matter of saints' days! and the like; so superstition has triumphed over science, and the priest over the philosopher. Such a state of worse than Mediæval ignorance, however, cannot endure for ever, and as education progresses in Russia we may look forward to her coming into line with the really civilised nations who are her neighbours. A remarkable series of observations and experiments in connection with the study of refraction have been made by M. F. A. Forel on and over the surface of the Lake of Geneva, who finds that the displacement of the apparent horizon due to refraction varies between +501″ and −272″, or a total variation of 773″. It must be noted that this applies to the horizon as viewed across a mass of water. Considerable discussion as to the nature and cause of the Gegenschein, or counterglow, has taken place during the past year, in which Prof. Barnard, Mr. Backhouse, Mr. Evershed, and Mr. Anderson have taken part. It does not, however, appear that any theory has yet been propounded, which will embrace and reconcile all the appearances that have arrested the attention of observers.

Turning now to the members of the Planetary System, we have nothing of any very great importance to record. Dr. G. W. Hill has attacked that, at present, practically insoluble problem—the mass of Mercury—from a novel point of view. The curious discordance between the values given by the perturbing action of this planet on Venus

and on Encke's Comet, drives Dr. Hill to the hypothetical conclusion that the materials forming Mercury, Venus, the Earth, the Moon, and Mars have approximately the same chemical constitution, derived from the primæval nebula from which our system was evolved. Finding, then, the mass of Mercury from analogy with Venus, the Earth, the Moon, and Mars, he finally deduces 11634200 as the mass-reciprocal. We greatly fear that he has simply wasted time over a most operose calculation. Yet another attempt has been made by Prof. W. Schur, of Göttingen, to measure the diameters and compression of Mars by the aid of the Repsold heliometer there, with the result that they indicate a compression of actually one-fiftieth. Employing another heliometer, also by Repsold, at Bamberg, and yet another, the Breslau one, at Strassburg, Dr. Ernst Hartwig arrives at very different results, inasmuch as he brings out the compression as equal to $\frac{1}{62}$. That the heliometer, though, is a trustworthy instrument for accurately measuring the diameter of a planet may very well be doubted. A series of valuable observations of Areographical detail have been made during the last opposition of Mars, by Mr. Gledhill, of Mr. Crossley's Observatory, with one of the new 9in. triple object-glasses. It is exceedingly interesting to find how the observations of this well-known and competent observer testify to the accuracy of the classical map of our neighbour in space, drawn by that splendid astronomical draughtsman, the late Mr. N. E. Green, F.R.A.S. Mr. Stanley Williams has also recorded a series of observations of his own of some of the so-called "canals" on this planet, but they call for no special remark. A most careful determination of the rotation period of Mars, made by W. F. Denning, F.R.A.S., makes it 24h. 37m. 22·70s.; Proctor's value, it will be remembered, being 24h. 37m. 22·735s., and Bakhuyzen's more recent one 24h. 37m. 22·66s. It is obvious that this quantity has now been determined with a very great degree of accuracy indeed. The detection of no less than 20 new Planetoids, whose orbits lie between those of Mars and Jupiter, has been announced; but at least seven of these have been proved to be identical with others previously discovered. Of the thirteen remaining ones, E E was discovered by Wolf and Schwassman at Heidelberg on Feb. 15, and E F on Feb. 17. The same observers have detected E O on July 17, E R, E S, and E T on Oct. 27; E U and E V on Oct. 31; and E W on Nov. 4; while Coggia, at Marseilles, first observed E L on March 31; Witt, at Berlin, E M on April 5; Coddington, at the Lick Observatory, E X on Oct. 2; and, finally, Charlois, at Nice, E Y on Dec. 4. As far as can be ascertained without an amount of investigation wholly incommensurate with the value of the result, 454 of these small bodies are now known. The comparatively favourable opposition of Eros during the present year will, of course, be utilised for the more accurate determination of the Solar Parallax. The latest determination of the eccentricity of the orbit of this remarkable body by Osten makes it amount to 0·2227695.

No discovery of importance has been made in connection with the superficial constitution and detail of the planet Jupiter; but the careful and elaborate researches and observations of Messrs. Denning and Stanley Williams among others have established the fact that the most curious discrepancies appear in the time of the rotation period as determined from spots in different latitudes, and even in some at the same distance from the planet's equator. If even now the question be asked: In what time does the solid body of the planet as a whole rotate beneath the superficial currents which we observe? the only reply that can be given is that we do not know. The work of the greatest interest in connection with this planet which has distinguished the past year is that performed by Prof. Barnard with the 40in. equatorial of the Yerkes Observatory, in his micrometrical measures of the Vth satellite, which have added notably to our knowledge of the orbit of this tiny attendant on the giant planet. *In limine* he finds that the line of apsides is moving round at the remarkable rate of some 2·465° per diem, or about 900° in a year; in fact that it makes a complete revolution in only 4·9 months. As the result of a most careful series of measures of the greatest elongations of the satellite, Mr. Barnard has finally determined its period to be 11h. 57m. 22·647s., and this he affirms is doubtless correct within 0·01sec. We have just said that Prof. Barnard computes the diurnal motion of the line of apsides of this satellite's orbit as 2·465° per diem. We may perhaps add that Dr. Fritz Cohn puts the motion of the perijove as being even more rapid still—i.e., as 911·7° annually, which would make its daily motion 2·496°. As far as Saturn is concerned, the chief interest may be held to reside in two papers by M. E. M. Antoniadi, F.R.A.S., read before the Society, on the constitution of the so-called "Crape" ring, in which he has successfully shown that the question of the relative brightness of the different portions of the planet's annular system may well be referable to the extent of the aggregation of their particles, and, in short, that it is more than probable that the albedo of the components of the three rings may be identical, and their brightness merely a function of aggregation. A far more sensational announcement in connection with this planet was made in March last, taking the form of an assertion that the examination of four photographic plates, taken at Arequipa with the 24in. Bruce telescope, had revealed to Prof. W. H. Pickering the existence of a 9th satellite to Saturn, *or* "a more distant outside planet." And here matters become a little vague, for we are told (or were told eight months ago) that the apparent motion was about 10·4" per diem, at a distance of 1,480" from the planet, and that a computation shows that if the orbit is circular, the period must be either 4,200 or 490 days! All this was made public last April, but as nothing whatever has since been heard of this remarkable new moon, there is some fear of its being relegated to the position of a celestial "Mrs. Harris." In connection with Saturn, it may be incidentally mentioned that Mr. Lynn has called attention in the columns of our contemporary, *The Observatory*, to a curious blunder which has been blindly copied from book to book concerning the time of the planet's rotation. It is put down as occupying about 10¼ hours, a quarter of an hour longer than the actual time occupied by Saturn in turning on his axis. The most extraordinary thing is that Sir John Herschel repeats this odd mistake. Of Uranus we have nothing to record, and of Neptune merely to mention that photographs of the planet and its satellite continue to be made at the Royal Observatory at Greenwich with the Thompson photographic equatorial with a view to the determination of the satellite's orbit.

The first, new, comet discovered in 1899 was found by Prof. Lewis Swift at Mount Lowe in California on March 3. It subsequently became a somewhat conspicuous object, and its head became duplicated, or was split into two. Photographed at the Lick Observatory, it was found that it had streamers and rudimentary tails diverging from the tail proper. The second discovery of an absolutely new comet was made by M. Giacobini on Sept. 29. Its orbit is seemingly hyperbolic. Numerous observations were also made of Brooks's, Coddington's, Denning's, Holmes's, Encke's, Perrine's, and Wolf's comets; but these are all periodic ones, and do not in strictness pertain to the year under review.

During the greater part of the year just past, scientific journals, quasi-scientific journals, pseudo-scientific journals, and journals and magazines without any atom of right to be considered scientific at all, vied with each other in predicting a superb display of those November Meteorites, now so familiarly known as the Leonids, on or about the 14th-15th of that month, and public expectation of a marvellous spectacle akin to that witnessed in 1866 was raised to the highest pitch. Two eminent astronomers, Dr. Johnstone Stoney, F.R.S., and Dr. Downing, F.R.S., the superintendent of the *Nautical Almanac*, did, it is true, put forth more than one paper showing how notable had been the perturbations of the stream since it crossed the Earth's orbit in 1866, and hence how relatively uncertain it was that anything approaching to the 1866 display would recur. But theirs were *voces clamantes in deserto*, and the general public were fed up to the last instant with assurances of a magnificent exhibition of celestial fireworks. It is quite needless to set down in detail what really happened, nor to what confusion the penny-a-liner would have been put had he had any conscience—which, happily for him, he has not. But if the display failed, as it did utterly, it was not without one amusingly sequent event; taking the form of the hoaxing of one of our contemporaries to an extent which involved the appearance in it of a sub-editorial article gravely written to show that the meteorites did arrive, and were seen after all. The evidence (?) adduced was embodied in a cock-and-bull narrative of the observation on the afternoon of November 15th, by two girls and a lad, of a tremendous shower of luminous objects through a thick mist, a shower lasting from 1h. 30m. p.m. to about 2h. 30m. This apparition was also visible to, and corroborated by, a washerwoman. It was alleged to have occurred in Wiltshire; but it was supplemented from Essex by a gentleman who professed to have seen (after luncheon, between 3 and 4 p.m.) "stars working in and out and round about." Unfortunately for the reputation for acumen of the scientific man who made all this public, this little piece of idiocy was utterly exploded and demolished by that unimpeachable authority, Mr. W. F. Denning, F.R.A.S., who has probably forgotten more about meteorites than the author of the paper itself ever knew. After what he has said we have probably heard the last about daylight meteorites.

In the stellar vault, one of the most important observations to be noted is that of Prof. Campbell, at Lick, of the variable velocity of Polaris in the line of sight. Observing this star with the Mills' Spectograph last August, he found velocities of approach varying between 5·34 miles and 9·44 miles per second, thus indicating that the Pole Star is a spectroscopic binary, having a period of very nearly four days. Prof. Campbell had measured this spectrum in 1896, and then deduced a motion of approach of 12·18 miles per second. Unfortunately, his observations were then made practically at multiples of the period, so that the variation was undetected. During August and September Prof. Campbell's discovery was confirmed by Mr. Ellerman, whose velocities of approach ranged between 6·59 miles and 11 miles per second, with a probable error of only ± 0·31 mile.

We may add that the same most diligent observer had also previously determined that in the case of γ Pegasi the velocity relatively to the Sun was on Aug. 27, 1897, one of 0·66 of a geographical mile per second of approach, and on the suceeding Sept. 8 one of 0·64; while in Aug. 25, 1898, the same star was receding from the Sun at the rate of 2·29 geographical miles per second, and on Sept. 17 at one of 2·26. The Rev. T. E. Espin, following up Dunér's researches, has shown

that of his stars of type IV., 55 per cent. are found within 10° of Galactic latitude, and 74 per cent. within that of 20°, thus indicating a fairly obvious connection between the two.

In connection with celestial spectroscopy, Prof. Keeler would seem to have shown that the spectrum of the Great Nebula (42 M) in Orion is unquestionably variable. The usual attempts have been made to determine the parallax of certain stars—with the usual results.

Celestial photography advances at a surprising rate, and the sensitised plate is taking the place of the human eye in numerous directions. The Astrographic Chart and Catalogue proceed apace, and the Sun is photographed whenever he is visible at Greenwich. Dr. Roberts's superb photographs continue to be taken with undeviating regularity, and we hear that a second of the invaluable volumes issued from the Crowborough Observatory is to appear immediately. Perhaps there is no more curious story in reference to the photography of the sky than that of the Crossley reflector, now at Lick Observatory. Purchased originally from Dr. Common by Mr. Crossley, the 3ft. reflector never did any good in its new possessor's hands; nor even after he had had it refigured by one of our most eminent opticians, were its capabilities to any extent developed. Now at Lick, it seems to have found its métier, and in the hands of Prof. Keeler to have produced results of the highest value. Mr. Keeler's photographs of the Ring Nebula in Lyra, and the Annular Nebula H IV. Cygni, together with that of the famous Cluster 13 M. Herculis (discussed by Mr. Palmer), have revealed much that is entirely new in the physical structure of those objects respectively. Many of the very beautiful slides printed from the Lick negatives have been exhibited at the Royal Astronomical Society. We grieve to record that Dr. Roberts's persistent attempts to photograph the Leonid stream have proved futile.

To Astronomical Literature about the average number of contributions have been made during the past year. Without any attempt at classification, we may mention among them Prof. Newcomb's new Tables of Mars, completing the series for the four inner planets; as also the same author's Catalogue of Fundamental Stars for 1875 and 1900. From the other side of the Atlantic, too, we get an admirable little work for the beginner under the title of "A Laboratory Manual of Astronomy," by Miss M. Byrd; and for the more advanced student, Prof. Campbell's "Elements of Practical Astronomy." In England we have had Mr. MacClean's splendid monograph, "The Spectra of the Brighter Stars," Monck's very important and interesting "Introduction to Stellar Astronomy," and last, but not least, the Eclipse volume of the British Astronomical Association. From Germany there reaches us Dr Ambronn's "Handbuch der Astronomischen Instrumentenkunde," an absolutely exhaustive treatise on the subject to which it is devoted, describing, as it does, practically every astronomical instrument that has ever been used in an observatory—or out of it. Even to those incapable of reading German, its 1,185 illustrations must perforce convey a wealth of information.

There is nothing special to chronicle in connection with astronomical instruments. The monstrous telescope of 328ft. focal length, at present being constructed as one of the attractions of the Exposition in Paris next year, is intended to cast an image of the moon 52½ft. in diameter on to a screen in a hall built to contain 4,000 spectators. It has been previously illustrated in these columns. What the definition is likely to be in the atmosphere of a city we would rather not speculate. Messrs. Trübner, the Leipzig publishers, have issued a work, entitled "Die Medial Fernrohre," by Herr Schupmann, describing a new form of combined reflecting and refracting telescope. We are in doubt whether this instrument has yet got beyond the descriptive stage.

Among matters of general astronomical interest, we may refer to the continued admirable munificence of Miss Catherine Bruce in subsidising astronomical research, her latest gift to the Columbia College University taking the form of a photographic telescope. She has further made a money gift to aid the computing work. In this country the gold medal of the Royal Astronomical Society was awarded to Mr. Frank MacClean for his splendid services, both personal and pecuniary, to celestial spectroscopy. As we write, the muster-roll of the Royal Astronomical Society contains the names of 691 fellows and associates, while the names of no less than 1,181 members are inscribed on that of the British Astronomical Association. We are further glad to learn that the Leeds Astronomical Society and the Astronomical Society of Wales both flourish.

Death has, happily, been less busy among astronomers of note than it has during some immediately previous years. The first one to be taken was good, kind, genial Miss Elizabeth Brown, whose purse and person were alike ever at the service of Astronomical Science, and who was known far and wide as an earnest student of Solar phenomena, and the head of the Solar Section of the British Astronomical Association. On three separate occasions did she, a delicate woman, undertake long and toilsome journeys to observe the phenomena of a total eclipse of the sun: once to Russia, then to Trinidad, and finally to Lapland. Her munificent legacy to the British Astronomical Association is very familiarly known. She died, after a very short illness, on March 5. She was followed on April 23 by Mr. Chas. Leeson Prince, F.R.A.S., who was, however, rather known as the leading authority on the meteorology of the south-east of England, than as having done any striking astronomical work. He was, however, the possessor of the historical Pearson refractor, and in conjunction with Mr. Lynn, exploded the figment that the principal division in Saturn's ring was discovered by William Ball, an error which had been copied from one astronomical work to another by rote. Mr. Prince possessed a fine library of Mediæval and later astronomy. On Aug. 16 died Prof. Bunsen, to whom, in connection with Kirchhoff, we owe the science of spectrum analysis. Mr. James Carpenter, whose decease occurred on Oct. 17, will be probably best remembered as the joint author, with the late Mr. Nasmyth, of a book on the Moon, which was long regarded as a work of very high authority. He was for some years an assistant in the Royal Observatory at Greenwich. He latterly took but little active part in astronomical pursuits. There was something sad in the death, on the 27th of October, at the age of 86, of the Rev. E. L. Berthon, seeing that he had only been readmitted as a Fellow of the Royal Astronomical Society on the previous 9th of June. To the world at large, his fame will probably largely rest on his invention of those collapsible boats which are now universally carried by passenger-ships and others all over the world. To the astronomer his name will be familiar as the inventor of the Romsey Observatory, the Equestrian Equatorial, and a multiplicity of other devices for assisting in astronomical observation. At the very meeting of the Royal Astronomical Society of which we have just spoken, he exhibited an ingenious device of his own for graduating the circular limb of an instrument and yet another form of equatorial mounting that he had invented. Only a fortnight later, on November 10th, there passed away, in the person of Mr. Nathaniel E. Green, F.R.A.S., one of the most brilliant and accurate astronomical draughtsmen that this country could boast of, and one whose drawings of Mars, Jupiter, and Saturn must always be classical, rivalling, as they do, the best photographs in fulness and minute accuracy of detail. His famous map of Mars, published in the R.A.S. *Memoirs*, must always remain the standard authority on the aspect of that planet at the time when the chart was drawn. He was President of the British Astronomical Association in 1897-98, and had sat for one year on the council of the Royal Astronomical Society. He died at the age of 76.

STANDARDISATION OF THE SUB-STAGE, AND OF THE INTERNAL DIAMETERS OF THE DRAW-TUBES OF MICROSCOPES.

THE following resolutions were adopted by the Council of the Royal Microscopical Society on Dec. 20, 1899:—That the standards by the Council in 1882 be withdrawn; that the standard size for the inside diameter of the sub-stage fitting be 1·527in. = 38·786mm.; that the gauges for standardising eyepieces be the internal diameters of the draw-tubes, the tightness of the fit being left to the discretion of the manufacturers; that the following four sizes of the internal diameters of the draw-tubes be adopted:

R.M.S., No. 1,	·9173in.	=	23·300mm.
R.M.S., No. 2,	1·04in.	=	16·416mm.
R.M.S., No. 3,	1·27in.	=	32·258mm.
R.M.S., No. 4,	1·41in.	=	35·814mm.

That a set of plug and ring-gauges of all the above sizes be kept in the Society's rooms, and that the public on payment of a small fee be allowed to inspect them; that the Society acknowledges with thanks the assistance it has received from many firms in reply to the circulars sent out.

Notes.—The substage gauge adopted is that which has been used by the English trade for many years past, the variation among different makers being not more than a few thousandths of an inch; R.M.S. No. 1 is the Continental gauge; R.M.S. No. 2 is the mean of the sizes used by the English trade for student's and small microscopes; R.M.S. No. 3 is the mean of the sizes used for medium-sized binoculars and other microscopes of a similar class; R.M.S. No. 4 is the maximum size for long tube binoculars. In all probability the eyepiece cap and apparatus to be used above the eyepiece will be standardised in a few weeks.

RESHARPENING OLD FILES.

APROPOS of a recently-proposed electrolytic method of resharpening old files, we are reminded of the statement once made that, after all, the best thing to do with an old file is to throw it away and buy a new one. This has been the conclusion arrived at by a great many whose experience has extended over the once much-talked-of sand-blast file-sharpening process, and the methods of etching and recutting, all of which have been practised with more or less success. Sand-blasting files have been claimed by some to be quite useless, as it makes the teeth shorter and simply raises an edge which has no durability. In recutting, the temper must be drawn, and the quality of steel used for files, or at least some of them, has been stated to be such that it deteriorates rapidly when rehardened. Right here, however, the point may be made, as, indeed, it has been by the advocates of recutting, that it all depends upon what grade of file one buys in the beginning. True economy ought to commence by purchasing that file which will yield the largest return for the outlay, and with this style of file recutting has been claimed to pay. The grade which will not stand recutting is the cheap, common kind, and buying this has been characterised as a waste of money at the outset. Whether, with the best kind of file that money can procure, etching, too, is an economical sharpening process remains yet to be definitely decided.—*Cassier's Magazine for January.*

FRUIT is now being shipped from New South Wales packed in the bark of the ti tree and the outer bark of the Melaleuca leucadendron, which is shredded into a sort of coarse chaff. These barks seem to have some peculiar power of preserving oranges during carriage. This may be owing to the elasticity of the packing and the fact that it permits of ventilation. Unless the bark is cut too fine, there is no sweating possible. The bark costs only 20dol. per ton.

AN AUTOMATIC VARIABLE-FEED DRILLER.

THE engravings herewith presented show the general appearance and construction of a drilling machine with a feed that is not only automatic but which at a given point automatically increases to four times its normal rate, and then changes back again, and proceeds until the piece of work is done, when it automatically releases.

This feature of an automatic variable feed was added to the regular drilling machine for the purpose of adapting it to a special purpose—i.e., the boring of malleable-iron hubs for the wheels of agricultural implements. These hubs have a bearing at each end, and are chambered in the middle by a core enlarged at that point. One man was to operate four machines on the job, and, of course, it is obvious that if he were required to release the feed, move the spindle downwards through the chamber, and again throw in the feed for each piece, he would be too busy; while, if the feed were allowed to run all the way through at the same rate, too many machines would be required for the given amount of work.

Referring to the drawings, Fig. 1 is a vertical side-elevation of the upper portion of the machine; Fig. 2 shows the opposite side; Fig. 3 is a front elevation; Fig. 4 is a sectional view on line A, viewed in the direction of arrow B. The feeding mechanism is as follows:—

On the horizontal upper cone pulley-shaft is the small three-step cone pulley, which drives the corresponding cone pulley on the worm-shaft below. On the latter shaft is a worm which drives the worm-gear *m*, which is keyed to the shaft *o*. To make room for the mechanism an extension or box-like receptacle, *p*, is built out on the side of the frame. A removable plate or cover, *q*, Figs. 2 and 4, is fitted to the extension *p*, forming a protection for the mechanism, and also having a bearing for the clutch-sleeve *h*. The sleeve *h* is keyed to the spur-gear *i*, and *h* also forms a bearing for the shaft *o*, which is fitted to turn freely in it. On the opposite side of the main frame is another bearing for the clutch-sleeve *g*, which has at one end a pinion, forming an integral part of it. At the opposite end is keyed the mitre-gear *n*, and this gear meshes with a similar gear on the worm-shaft *r*, Fig. 1. This latter shaft revolves in suitable bearings in the tipping-frame *s*, and the worm keyed to the shaft *r* engages with the large worm-gear, which is keyed directly to the stud carrying the pinion which feeds the main spindle. The lever *t* has a projection which bears against the tipping-frame *s*, and when it is in position, as shown in Fig. 1, the worm is in mesh with the worm-gear and the feed is going. The lever *t* is held in position by the latch *t'*, and link *t''* connects *t'* to another lever *t'''*, which is pivoted to the frame above.

When the trip-collar *u* engages with the end of *t'''*, the latch *t'* is lifted and the lever *t* is allowed to fall, releasing the feed. The spindle is returned to its starting point by means of the handles on the large worm gear shaft.

Between the two clutch-sleeves *g* and *h* on the shaft *o*, Fig. 4, is fitted a sliding clutch-collar, *f*; it is splined to *o*, so that the collar and shaft must always turn together. With this collar engaged with the clutch-sleeve *g*, the normal rate of feed is obtained; but when the collar is shifted so as to engage with the sleeve *h*, then the movement is carried to the clutch-sleeve *g*, through the medium of the gears *i*, *k*, *l*, and *g*. The gearing is arranged so as to obtain an increase of feed equal to four times the normal feed.

On the side of the frame, Fig. 5, is secured a bracket which forms a bearing for the sliding rods *a* and *b*. Rocker arm *c'* is connected to the rods *a b* by two short links and to the bell-crank *e*, Fig. 4. This bell-crank throws the clutch-collar *f* in either direction.

On the end of *a* is an extension *a'*, which is pivoted in such a manner that it will lift upward, but it cannot be pressed downward beyond the horizontal line. The extension on the trip-collar *u* engages with bevelled edge of *a'* and forces it back-

ward. This moves the clutch-collar f to the right, and thus puts on the fast feed. A spring not shown in the drawing, but attached back of c', assists in this movement. The spindle will now feed four times as fast as before, until the trip-collar comes in contact with the sliding rod b (which has been thrown forward by the previous movement), and this throws the clutch-collar back again and restores the working rate of feed. The spindle then continues to feed until the collar contacts with lever t''', when the feed is stopped automatically. The end a' attached to a is lifted by the upward movement of the collar, and by means of a spring it immediately snaps back into position ready for the operation, as described. In the machine described the total feed of the spindle is 14in., and the length of the intermittent rapid feed is only 2½in., but this can be varied to suit conditions. It is built by Baker Brothers, Toledo, Ohio.—*American Machinist.*

DIAGRAM SLIDES.*

IN these days of technical schools, where demonstrations by means of the optical lantern play such an important part, the lecturers, no doubt, often require diagram slides, so probably a few remarks on this subject may not be amiss. Most amateurs in the course of their photographic career have a number of light-struck plates which, I suppose, are generally consigned to the dustbin. Fortunately, I saved mine, and collected a great number of all makes and all sizes. Well, one day last week I wanted a few diagram slides, and commenced coating the glass plates with some wretched black stuff of the Brunswick black genus; however, the varnish did not work satisfactorily, and then I thought of these aforementioned light - struck plates. So I mixed up a strong pyro-ammonia developer, and developed, or more correctly, blackened them in full daylight. They were then plunged directly into a solution of ferrous sulphate. This formed, with the pyro-gallol already in the film, a black ink-like substance, intensifying the already blackened plate. They were then washed for a few minutes and dried. When thoroughly dry, they were cut with a glazier's diamond to the standard lantern size, and by means of a sharp needle and a ruler I scratched my diagrams upon them. These slides show upon the screen as brilliant white lines upon a black ground.

These white lines can be coloured with the greatest ease by painting on alcoholic solutions of aniline dyes, to which has been added a little dammar, mastic, or other similar gum-resin; this forms a dye-varnish and dries rapidly. One of the principal advantages to be gained by making white lines upon a black ground is that, if by chance any of the dye-varnish exceeds the place which it should occupy, the smudge is not visible on the screen, being obscured by the dense black ground.

The black line on white ground slides are most conveniently made by drawing with pencil on fine ground glass, or even plain glass coated with matt varnish, and subsequently coating with ordinary crystal varnish, which renders the whole matt surface perfectly transparent.

Coloured diagrams on white ground are best made on plain glass by means of a pen and inks composed of aqueous solutions of aniline dyes mixed with a small quantity of gum arabic. However, for my own part I prefer the previous process, which, I believe, is unequalled for the extempore projection of coloured spectra.

There is one little point which may be interesting, not being universally known: that is, if one makes a fine scratch or slit across one of these blackened plates with a very sharp needle, and holds this plate close to the eye, looking through the slit at a distant candle or gas light, most beautiful spectra are seen, extending on both sides of the light in a position at right angles with the slit.

Sometimes a diagram in a book is required to be copied to illustrate a lecture. This should be done by means of the copying camera, placing the book to be copied in a large printing frame with the diagram pressed into close contact with a clean sheet of glass. The object should be lighted from one window only, no side lighting being allowable, as it casts a sheen on the glass in the printing frame, and accentuates the grain of the paper. A small stop should be used in order to obtain better definition. The plate employed should by preference be a slow lantern or process plate, for these give density *ad lib.* The best developer is ferrous oxalate, which has least tendency to reduce unexposed bromide of silver, and thus keeps the lines clear, only I ought to mention that more patience must be exercised during development on account of its slow action.

THE "MECHANICAL WORLD" POCKET DIARY and YEAR BOOK for 1900 (Manchester: Emmott and Co., Ltd.) is, as usual, a very useful collection of tables, rules, &c., for engineers and craftsmen.

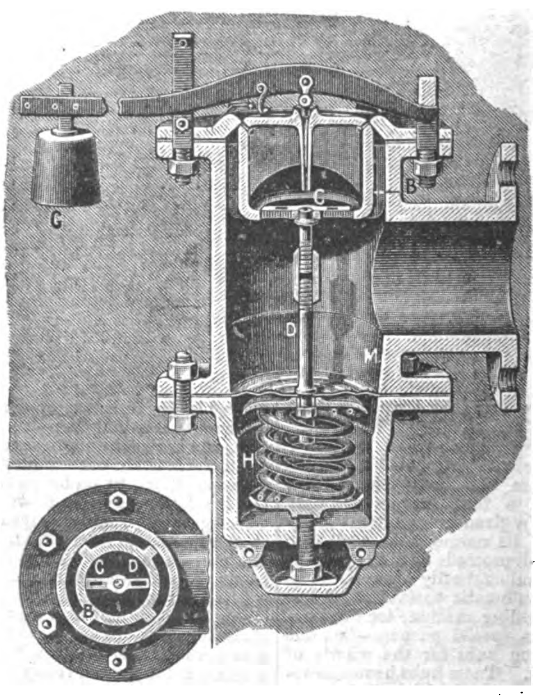
PARSON'S SWITCH - THROWING DEVICE FOR CARS.

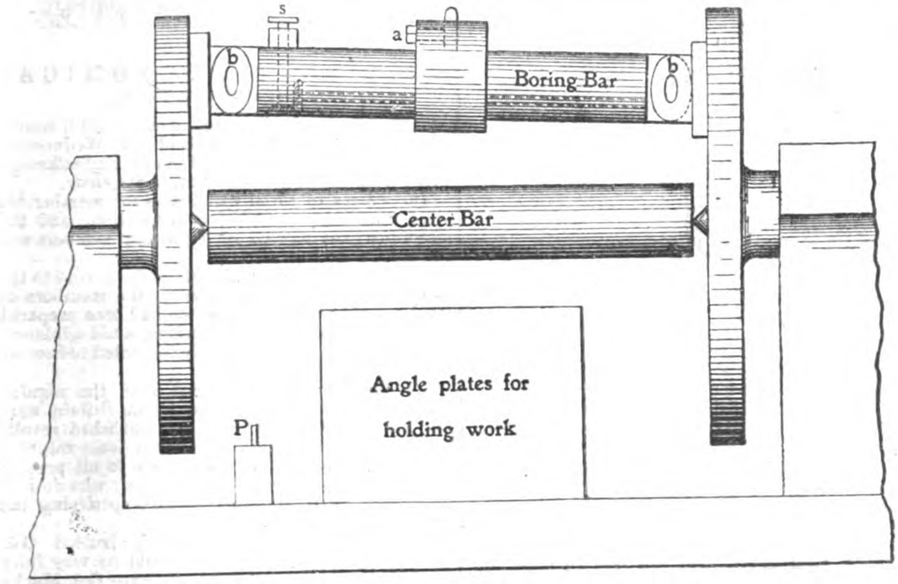
THE illustrations represent, in perspective, section, and plan, a new form of switch-throwing mechanism, which is operated by the motorman or driver of a car. The device is the invention of Swan Parson, New Britain, Conn. In the platform of the car a foot-rod is vertically mounted in a bracket and provided at its lower end with a switch-operating plate. The foot-rod is normally held in raised position by means of a coiled spring. The switch-operating plate, as shown in Fig. 4, representing an inverted plan view, comprises two guides having obliquely-disposed edges converging towards the rear of the car. Two spring-pressed guide-fingers are pivoted in a depression at the rear ends of the guides. A pointed central guide is located in the rear of the oblique guides, and is adapted for contact with pivoted fingers. When in contact with the pointed guide, the fingers and corresponding oblique guide form a straight line. The switch-tongue is provided with a projection (Figs. 1 and 3) normally spring-pressed outwardly and designed to engage the switch-operating plate on the car. In order to throw the switch the foot-rod is depressed, so that the projection on the switch-tongue engages one of the oblique guides. Let it be supposed that it engages the upper guide in Fig. 4. The oblique guide will throw the switch towards the central position until the projection comes in contact with the upper spring-pressed finger in Fig. 4. The finger will thereby be pushed back until it assumes the position shown by dotted lines and forms a continuous guide for the switch-tongue projection, with the upper oblique guide and lower edge of the rear guide. The tongue is hence gradually thrown. If the other finger were engaged by the projection, the switch-tongue would be thrown in the opposite direction. The device, it is evident, will throw the switch in either direction, without any difference in the operation. Even if the projection were not engaged by one of the oblique guides, the switch would still be thrown by a finger and the rear guide. The device cannot, therefore, fail in action. —*Scientific American.*

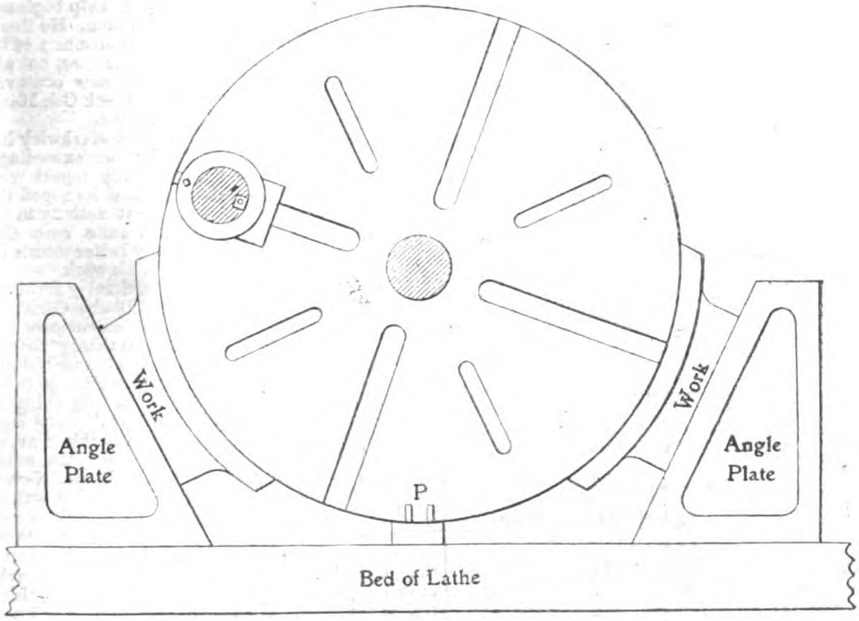
A NEW SAFETY-VALVE.

THE sectional and plan views of a "new" safety-valve are given by *La Nature.* The plate submitted to the action of the lever that carries the counterpoise D rests upon the top of a small cylinder, B, movable in a vertical direction in the valve-box. This cylinder carries at its lower part a transverse piece, C, provided with two apertures, and into which is screwed a vertical rod. This latter is connected through a nut with another rod, D, which is fixed to a thin metallic disc, M, of which the circumference is clamped between the flanges of the valve-box. Beneath the disc M there is a double



spiral spring, H, which rests upon a disc that can be manœuvred by means of a screw protected by a cover hinged to the bottom of the box. The base of the latter is provided with an aperture for the purpose of revealing the existence of any leakages of steam that might take place through the disc M. The surface of the disc M is such that the pressure exerted upon it by the steam is equal to that exerted upon the cylinder B and the rod C. Such pressure is obtained by regulating the tension of the spiral spring by means of the screw at the bottom. By acting upon the nut that connects the





rods D, the cylinder B may afterwards be brought into contact with the plate submitted directly to the action of the lever carrying the counterpoise. Such regulations will remain in force for pressures up to an amount determined by the conditions of equilibrium adopted; but it will no longer exist if the weight G be changed or the lever rendered stationary. In fact, if the weight be increased, the cylinder G will immediately descend, and the steam will escape. In like manner, if the lever be fixed, the pressure will cause the disc M to yield and carry along the cylinder B through the intermedium of the rod D.

A TAPER BORING RIG.

WHEN designers put the dome on the taper course of a waggon-top boiler they evidently do not think of the shaping of the reinforcing ring, which must fit the sheet, or that a special boring rig may be necessary.

These rings are usually planned out on a planer having a special head with a circular movement; but the taper has to be treated differently. At the Baldwin Works we recently saw a big wheel lathe doing duty as a boring mill for this work in a manner that was both ingenious and extremely practical. A heavy centre-bar or distance-piece was between the centre as a brace, and the boring-bar bolted by special foot-pieces to the face-plates at the proper distance for the radius and at the correct angle. The work—and two rings were being bored at a time—was held on angle-plates, as shown by end view, and fed into the proper distance. The foot-pieces for the bar had two ears or lugs, between which was bolted the flattened ends of the bar *b b*, so that any desired angle can be obtained. The boring-bar is of the usual type, although with slight modifications, and the star wheel *s*, striking pins P, feeds the tool-head along in the usual manner.—*Locomotive Engineering*, N.Y.

FORMALIN AS A PRESERVATIVE.

ALTHOUGH as a preservative medium for perishable zoological specimens, formalin has scarcely realised all the expectations entertained on its introduction, yet there can be little doubt that it has a great future before it, and that for certain purposes it is likely to prove invaluable. It has, however, many undoubted disadvantages, and in the minds of some museum officials these disadvantages appear to outweigh its manifest valuable properties, so that an unfavourable opinion is entertained of it in general. On the other hand, those who weigh more carefully the *pros* and *cons.*, realise that, under proper conditions and restrictions, its value is really very great.

As regards its disadvantages, it must be admitted that it is unsuitable for the permanent preservation of specimens that are likely to be manipulated, as not only are its effects on the hands of the worker most unpleasant, but in many cases it renders the tissues of the specimens themselves so hard that they are practically unworkable. Then, again, it is quite unsuited for all specimens containing calcareous matter, such as molluscs, echinoderms, and crustaceans; while unsatisfactory results appear to have been obtained in the case of certain insects and myriapods. Moreover, it does not seem to be well suited for the preservation of reptiles, and it is said to deteriorate the colours of bird-skins.

Turning to its advantages as a permanent preserving fluid, it is acknowledged to be unrivalled for specimens of watery and "flabby" animals, such as jelly-fish, rendering them more coherent and less likely to disintegrate than any other known medium. Apart from this group, it does not, however, appear to be at present used to any great extent in the exhibition series in the British Museum; although we have reason to believe that its possibilities are occupying the serious attention of the officials. In the series of worms, all the more valuable specimens that were received in formalin have been transferred to spirit, and only the commoner forms left in the original medium. Of the six specimens of eggs, embryos, and larvæ of Lepidosiren paradoxa recently added to the exhibition series from Mr. Graham Kerr's Paraguay collection, three are in alcohol and three in formalin; the latter having been sent home in that fluid, and it being thought not advisable that the medium should be changed. If these six specimens are carefully watched, they will afford a test-case of the comparative value of the media. At present, we believe, none of the exhibits in the "Index Museum" are in formalin.

For sterilising freshly-killed specimens of mammals and birds, as well as eggs, that have to be sent some distance to a museum in the flesh, there can be no doubt that formalin is invaluable. And it is no less valuable to the field collector of mammals, not only on account of the small bulk a sufficiency of the fluid occupies, but also from the marvellous preservative power of the fluid itself. According to Mr. O. Thomas (who reports very favourably of it for this purpose), commercial formalin, which is itself 40 per cent. under proof, must be diluted with no less than twenty-five times its own bulk of water before use. Moreover, whereas when mammals are preserved in spirit it is necessary to allow a very large amount of fluid to each specimen, when formalin is employed the vessel may be crammed as full as possible with specimens, which are preserved without exhibiting the slightest traces of putrefaction. When received at the British Museum all such specimens are, however, immediately transferred to alcohol, on account of their unsuitability for handling when in the original medium.

The foregoing instances suffice to show that for certain specific purposes formalin has advantages as a preservative medium not shared by alcohol. But, as many of our readers are aware, another application of formalin has been recently proposed by Dr. G. de Rechter, of the Brussels University, who, in the twelfth volume of the *Annales de l'Institut Pasteur*, 1898, has advocated the use of currents of formalin vapour for the preservation of animal specimens. The advantages claimed for this method are that it preserves the specimens in practically the same condition as they were left at death; the tissues not being hardened, while hair and feathers are uninjured alike in texture and in colour. Experiments in this method have been recently undertaken in Mauritius by Mr. Camille Sumeire, of the Albion Dock Company, who has constructed an apparatus on the general lines of one suggested by Dr. de Rechter, in which specimens can be subjected to constant currents of formalin vapour. And it appears from an illustrated report published in the *Bulletin de la Société Medicale de l'Ile Maurice* for July 18 that the results of these experiments have proved eminently satisfactory.

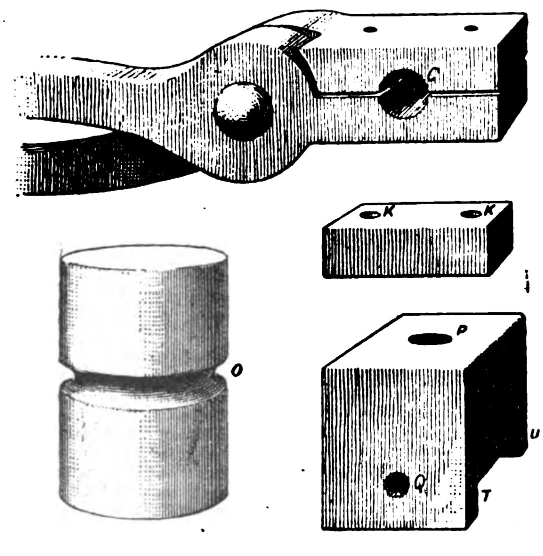
A freshly-killed guinea-pig placed in the apparatus for a period of twenty days was found to be a perfect state of preservation, and when exposed in the open in the museum for a further period of eight days, was likewise found to be intact. Moreover, a culture of bacilli exposed in the apparatus at the same time as the guinea-pig was found to have become completely sterilised.

As was well remarked by Dr. de Grandprè, superintendent of the Port Louis Medical Museum, the potential advantages of such a method of preservation are likely to prove very important. And it is urged that the process may be specially valuable in cases of suspected poisoning, as bodies can be preserved for any length of time in a state suitable for examination. From a natural history point of view the invention has likewise almost unlimited possibilities; and Mr. Sumeire hopes to be able shortly to supply the museums of Europe with examples of the mammals of Mauritius as fresh as when alive, instead of in the condition of ordinary spirit-specimens. Indeed, negotiations are already opened with the director of the Paris Museum for the transmission of such formalined specimens to the institution under his charge. We wish all success to the new venture.—R. L., in *Nature*.

AUTOMOBILES IN FRANCE.

THE early development of the modern automobile vehicle in France has naturally led other countries to look thither for the results of experience. This is the more natural because there has been much competition, besides various trials, exhibitions, and reports, while the freedom which has been permitted in the use of all kinds of motor vehicles renders the information thus obtained of a most practical nature.

The general reports of the competitions of 1898 and 1899 have appeared in various publications, and have been reviewed from time to time in these columns, but now we have a critical discussion of the engineering side of the information obtained from these trials in the form of a paper presented before the *Société des Ingénieurs Civils de France* by M. G. Forestier, the well-known inspector-general of Ponts et Chaussées.



So far as automobilism as a sport or recreation is concerned, M. Forestier regards the question as entirely settled, and hence devotes himself entirely to the practical side of the problem of commercial mechanical traction on public highways.

The trials of 1898 were of heavy road vehicles, and for this service the only motive power attempted was either steam or gasoline.

The steam vehicles were fired with coke, with heavy oil, and with gasoline, while in a number of instances internal combustion motors were used, the gasoline acting directly in the cylinders.

For tabulated details of the tests, reference must be made to the paper of M. Forestier, but the general conclusions are that steam power is the best where sudden demands for power are made, such as steep grades or starts on ascending inclines, while an internal combustion motor is satisfactory for fairly level roads, and is much lighter in weight. Both classes of motors showed a notable advance in economy over similar vehicles tested in 1897, and there is prospect of further improvement in this respect.

Deducting the weight of the vehicles, the cost of hauling merchandise on common roads by steam motor vehicles is given as 0·373fr., 0·200fr., and 0·140fr. per ton-kilomètre, according as they are operated with one-third, two-thirds, or full load; while for the internal combustion motor the corresponding costs per ton-kilomètre are 0·673fr., 0·369fr., and 0·268fr.

Since the average cost of animal traction under similar conditions is about 0·25fr. to 0·30fr., it is evident that mechanical hauling of merchandise can only compete successfully with horses when full loads are carried. When unbroken loads of 9 to 10 tons are to be transported at speeds above 4 kilomètres per hour, the motor vehicle is the only one which can be used, and it is believed that the improved merchandise trucks will prove capable of speeds up to 6 kilomètres with heavy loads as a consequence of the experience gained from these trials.

The details of the trials of the light vehicles are too voluminous to be discussed at the present time, but the following tabulation of costs per day for the operation of cabs and delivery waggons will be of interest:—

	Cost per day.		
	Horse.	Gasoline.	Electricity.
Cab	19·26f.	16·27f.	18·48f.
Delivery waggon.	16·72f.	12·80f.	14·80f.

The figures include interest, depreciation, and, in the case of the electric vehicles, maintenance of accumulators.—*Engineering Magazine.*

SWAGE FOR USE WITH A STEAM-HAMMER.

ONE of the contributors to the *Blacksmith and Wheelwright* says that he has to work a steam-hammer and make with it a thousand and one things. He says:—It is not an easy matter to change tools and dies. Not long ago I had some bolts to make out of 1⅛in. round iron; the bolts were to be 1in. in diameter. To draw down the bolts, cut off, reheat (after I had changed the tools), and swage was just a little too much trouble. I finally hit on a novel idea, which I now give to you to show to others; perhaps the tool may have been made before, but as the hammer I am working is the only one I ever saw, I am not at fault in telling you what I have done, more especially when I have done a good thing. The novel idea is simply a swage which opens and shuts, or a swage made like a pair of tongs.

The jaws are made of steel, to prevent the same becoming injured. I made two iron cushions ⅜in. narrower than the swage and ⅜in. shorter, 1in. thick, with counter-bored holes, K K, so as to bring heads of screws below the surface. Two of these cushions are necessary—one top, one bottom—screw them on to the jaws as per holes marked in the same; make the jaws 4in. long, 3⅜in. wide, hole to suit. After the bolt is hammered enough stick in swage and swage, by having the hammer come down on the same. After the bolt is swaged I cut it off and throw it in the fire with the other piece. While it is heating I lift the heading block and place it on the anvil; the top P with hole Q outside, with lug T to hold it on anvil, U corresponding lug forming the recess which straddles the anvil. When hot the bolt is inserted in the hole and gets one light tap with the hammer; then I place on the heading tool and give it a couple of raps with the hammer, and the job is done. This header is shown in lower part of sketch, O being sunken for an iron gad handle; the bottom is cupped out to suit head; make in length and swage to suit, and of mild steel.

ERRATUM.—Column one, page 438, last line, 18h. 42m. 46·60s. should quite obviously be 18h. 42m. 46·80s.

USEFUL AND SCIENTIFIC NOTES.

COAL is widely distributed throughout India, except in Bombay and Sind, the North-West Provinces, and Oudh, Rajputana, and Mysore, where the mineral is either scantily distributed or entirely absent. The seams in Bengal and Assam are frequently from 50ft. and 80ft. to as much as 180ft. in thickness. The pits are often of considerable depth; at present the deepest appears to be about 700ft. In many cases the working of the seams leads to the escape of little or no fire-damp, so that the miners are able to work with naked lights. In 1895, 235 collieries were at work, but in 1896 only 172 were in active operation. At the present time Bengal produces more than three-fourths of the coal mined in India.

THE Royal Agricultural Society of England has issued the prize sheet for the meeting to be held at York from the 18th to the 22nd of June next. The total value of the prizes offered — exclusive of champion prizes and medals given by the leading breed societies—is £6,820, of which £1,676 are contributed by the York Local Committee. In the implement department the Society will offer prizes of £40 and £20 for general purpose horse-power cultivators, prizes of the same amounts for self-moving steam diggers, a prize of £50 for milking machines, and prizes of £20 and £10 in two classes for sheep-shearing machines, to be worked by power and by hand respectively. The entries for these classes close on March 15.

INDIAN COAL varies much in composition and quality. Most of it is quite suitable for ordinary purposes, while some of the samples—e.g., certain of those from Bengal and Central India—are of excellent quality, equal to that of some of the best British coals. Though the coal in Bengal varies greatly in quality, much of it is excellent, the fixed carbon ranging between 50 and 60 per cent., and the calorific value exceeding 6,000cals.—equal to about ten British thermal units—while the ash often does not much exceed, and in some instances falls below, 10 per cent., and the sulphur is frequently present in but very small proportion. A great deal of the Bengal coal is serviceable steam coal. Many samples cake well and contain little sulphur, and the coke is, therefore, suitable for iron smelting.

SCIENTIFIC SOCIETIES.

BRITISH ASTRONOMICAL ASSOCIATION.

THE second ordinary meeting of the 10th session of the B.A.A. was held on Wednesday, Dec. 27, at Sion College, Thames Embankment, Mr. W. H. Maw, the president, in the chair.

The names of seven candidates for membership were read and passed for suspension, and the election by the council of eight new members was confirmed.

The President asked Mr. Maunder to read to the meeting an inaugural address to the members of the Variable Star Section, which had been prepared by Colonel Markwick. He added, amid applause, that Col. Markwick had kindly consented to become the director of the section.

Col. Markwick pointed out that the regular observers of variable stars in Great Britain were few and far between, and the published results correspondingly small. He offered some valuable advice to observers, and appealed to all present members of the section, as well as any who desired to join, to send him their names, specifying the instruments available.

Mr. Maunder said he sincerely trusted Col. Markwick's appeal for names would be very fully responded to. He was perfectly sure Col. Markwick would do everything in his power to make the section a success, and especially to help beginners in the work of variable-star observation. He therefore hoped that not only all the old members of the Section would send in their names at once, but also there would be a large number of new observers who would enter on this work, and seek Col. Markwick's aid, and give him their support.

The President remarked that Col. Markwick had inaugurated his directorship by an exceedingly practical address, and he could only repeat what Mr. Maunder had said—namely, that he hoped this would mark the beginning of great activity in the Variable Star Section. He was quite sure Col. Markwick would not wish for any better return for his trouble than ample support in his work.

Mr. Petrie read a paper by Mr. Stanley Williams entitled "Considerations on the Double Canals of Mars." The writer said his recent experiences had not been favourable to the "optical theory" of the duplicated canals, the theory which ascribed observed duplications to the telescopic image being out of focus, whether directly by bad focussing or by what had been termed "diplopia." The conditions were seldom quite satisfactory this year, as regarded steadiness of definition and the small apparent size of the planet was also adverse. Nevertheless, on two or three nights the seeing was so good that the results appeared to him conclusive on the subject. The Canal Cerberus, for instance, appeared continually double for half an hour at a time, except when a wave of atmospheric disturbance swept over the planet and made everything appear confused. No change of focussing had any effect beyond making the double canal appear indistinct, and ultimately to disappear. Also by no change of focussing was it possible to make a single canal appear double. Having enlarged upon an opinion expressed by himself in the *Observatory* for June, 1899, that the double canals of Mars were due in reality merely to two ordinary single canals being seen apparently close together, Mr. Williams proceeded: "For these and other considerations, the fact of particular canals being described as double at one observatory and only single at another, would really have no bearing upon the reality of the observed duplication of canals, especially since the personal element enters so largely into all observations of delicate planetary details, the visibility of which is moreover dependent so greatly upon the conditions of seeing, which are seldom the same at two different observatories at the same time. . . . It would seem that even the supporters of the optical theory regard the duplicity of one canal—the Nilokeras—as real. Yet there is absolutely no difference in appearance between the duplicity of this canal and that of many others! There is a double bay on Mars well known under the name of 'Dawes' Forked Bay,' the reality of which has never be questioned. There is also a double canal—the Gehon—the two components of which run from the two inlets of Dawes' Forked Bay. It seems hardly logical to admit the duplicity of the bay whilst refusing to acknowledge that of the canal. . . . In every theory of the kind now in question, the really crucial test must always be actual experiment upon the object itself, and it will be clear, I think, from the foregoing that the optical theory of the duplication of the canals of Mars breaks down altogether under such crucial test."

M. Antoniadi contributed some notes on this paper, contending that it was not possible to "experiment directly on Mars," pointing to what he regarded as incongruities in the paper, and urging that in considering the double canals as objective realities, Mr. Williams was, of course, unable to account for the fact that they appeared

at one and the same time single and double to different observers.

Father Cortie said he was not a Martian observer, but there was one point in Mr. Stanley Williams's paper that struck him—namely, the analogy the writer drew between observing the canals of Mars and double stars. He (the speaker) did not think the argument held, because in observing double stars they were observing two distinct bright points upon a black sky. In observing the canals of Mars they were observing on a background which, of itself, was a very difficult object to see, and was continually changing in definition. They could not very well compare photographs of stars with those of planets. The former were perfectly clear, but no one had yet been able to obtain a good photograph of a planet. Even Prof. Pickering's photographs of Saturn and Jupiter, for instance, were very blurred. Therefore, he did not think that this particular argument for the objective reality of the doublings of the canals of Mars held. With regard to the doubling of canals he had no theory on the point; but, from experience in observing the spectrum, he could say that when the eye became tired the lines began to double. It then became necessary to alter the focus, and after a short rest the lines were seen to be single. Perhaps this had something to do with the doubling of the the canals on Mars; he did not know—he only threw out the suggestion.

Mr. A. J. S. Adams said that the eye could often be focussed so as to double a line, but it so happened that one line was always darker than the other. He wished to know whether the Martian doubles were equally dark, or whether one was slightly lighter than the other.

Mr. Goodacre, speaking as to Mr. Stanley Williams's remark concerning the duplicity of lunar rills, said that on one occasion, when observing Petavius, which contained a very coarse rill, it suddenly appeared to him to be doubled; but, testing the telescope, he found it to be slightly out of focus, and when he got the focus right the rill returned to its single condition again.

Capt. Noble said it was noteworthy that the most wonderful things ever seen on Mars had been seen, perceived, or imagined—whatever they chose to call it—when the planet was a long way from the earth, and unfavourably situated. During the opposition of 1877—that most favourable opposition, when those superb drawings which would be always classic by the late lamented president of the association, Mr. Green, were made at Madeira—none of these marvels were visible; but when they had the planet a very long way off the sun and earth, and perhaps showing gibbosity, in fact, in a generally unfavourable position for observation, it was surprising what could be seen upon it.

Mr. Holmes remarked upon what Capt. Noble had said about the markings on Mars being more visible when long past opposition. He himself had made some remarks upon the point before; but upon reflecting on what happened in case of the moon, he could not help seeing that there might be something that might cause the markings to be more visible at quadrature than when in opposition. For instance, dark markings on the moon were very much more easily seen at other times than full; when the moon was full they did not see them. When it was some distance from full the markings were very much more perceptible. He did not see why something of the kind might not be quite analogous to that in the case of Mars; but at the same time he had not the slightest faith in the duplicity of the canals. As to the point Mr. Stanley Williams raised about double stars, no one could have looked at them very much without knowing they very often did double. He had spent some time observing particular cases, and had been quite unable to tell whether he saw two or four. That was largely owing to the state of the atmosphere, and what would double a star in that way would also double other objects. Mr. Williams seemed to raise a distinction between a double canal and two single canals side by side. He (Mr. Holmes) did not quite follow the distinction. Two single canals side by side would be apparently much the same thing as a double canal.

Mr. Newbegin desired to be allowed to corroborate a remark made by Father Cortie, who mentioned having seen one of the lines of the spectrum doubled. He himself had seen the C line doubled, and he did not know whether it had been through the fault of the eye or the fault of the light. Mr. Thwaites had seen the same thing. Until that gentleman drew his attention to it, he had never seen such doubling, but since that time he had on one or two occasions seen the C line in the spectrum of the sun doubled.

Mr. Saunder said he had made some experiments on the duplication of lines in the telescope with the micrometer. The webs of the micrometer could very easily be seen double by putting the eyepiece a little out of focus. He discovered in that way what he had a suspicion of before—namely, that he had a slight amount of astigmatism in his eye. It was such as to require a cylindrical lens of 50in. focus to correct it; but this was enough to cause the lines in one direction to go out of focus very much before those at right angles to them, showing that a slight error of focus would effect a sensible duplication. He did not quite follow what Mr. Holmes said about the dark markings on the moon disappearing at the time of Full. What markings disappeared?

Mr. Holmes: The shadows.

Mr. Saunder: The shadows disappear because they are not there when the sun is high.

Mr. Holmes: Would not the same thing follow in the case of Mars?

Mr. Saunder: That is, supposing the canals are shadows.

Mr. Holmes did not suggest that, but merely thought, as we do not know what the nature of the markings is, they should not condemn their existence because of non-visibility at times of opposition as compared with other times.

Mr. Crommelin could corroborate what Mr. Saunder said about it not being difficult to make a spider line in the telescope appear double when out of focus. He noted it independently long before M. Antoniadi suggested this interpretation of the duplication of the canals. He also noticed, as Mr. Saunder said, that the ease with which they could duplicate the line depended on its inclination to the vertical. Of course, that was the question of the astigmatism of one's eye. With him a horizontal line was much easier to duplicate than a vertical. He did not think M. Antoniadi was quite fair in taking Mr. Phillips's observation, when Mr. Phillips saw the canal doubled for a few seconds, for, as Mr. Phillips said, it was obviously only the effect of atmospheric unsteadiness. Mr. Stanley Williams was talking of canals that appeared double during the whole evening; so that it was scarcely fair to compare the two things. Mr. Stanley Williams' point was a strong one about the two canals from the two portions of "Dawes' Forked Bay." No one had ever questioned the real duplicity of that bay, and the two canals that went from the two heads of the bay would certainly seem to be real. It was only some canals Mr. Williams was contending for. There were some instances which he would allow to be caused by optical illusion. If they could get any real instances of duplication it would be an interesting result, and this he (Mr. Crommelin) thought Mr. Williams had established as regards the instance mentioned and a few other canals.

Mr. Fletcher said that, in the case of astigmatism, part was muscular and part structural. That which was structural was permanent; that which was muscular was variable. This would explain why a line might appear single one moment and double the next. He desired to know whether those canals which were at right angles to the sun's rays at any particular time were more distinct than others so placed that at the same time the sun's rays shone along rather than across them, which should be the case if the canals were due to shadows caused by inequalities of level.

The President said they were very much indebted to Mr. Stanley Williams for his very interesting paper, and also to M. Antoniadi for his note upon it, which had aided the discussion very much. He (the President) could quite confirm what Mr. Holmes had said, that there were many cases in which it was very difficult to see whether a star was single or double, or whether a double-star was four stars, as Mr. Holmes put it. The duplication of the micrometer wires also was a very common phenomenon. Anyone who had done much double-star measuring must have had hundreds of experiences of that kind. It was also noticeable that occasionally, when they had been at work some hours, they would get a duplication without a change of focus; that was that the focus that suited their eye when they started work did not suit it after a long spell of work on a particular pair of stars. They would then naturally refocus; but before doing that, they certainly did get duplication of the webs. He personally had never noticed any difference in the duplications of horizontal and vertical wires. That was purely a personal matter; but they would find sometimes, in using high powers, that the very small difference of focus they required for the nearer of the movable webs as compared with that for the more distant web was quite sufficient to give duplication of one and not of the other. Of course, with moderate powers that was not noticed; but with high powers, the very small difference in the plane of the two webs was quite sufficient to determine the duplication of either the near or far web, as the case might be.

The President called upon Mr. Maunder to make an announcement respecting the arrangements made for the eclipse expedition of next year.

Mr. Maunder read the circular which had been drawn up. This stated that, subject to a sufficient number of passages being actually taken before Jan. 31, the Royal Mail steamer *Tagus*, or a sister vessel, would be engaged. The vessel would start from Southampton at six p.m. on Friday, May 18, calling at Cadiz and Alicante, and arriving at Algiers at six a.m. on Thursday, the 24th. Leaving Algiers on Tuesday, the 29th, at six p.m., the vessel would call at Alicante, Gibraltar, and Lisbon, being timed to arrive at Southampton at seven a.m. on Monday, the 14th of June. It was hoped that the members of the Association would divide themselves into three principal groups: Those observing the eclipse (1) in the interior of Spain, (2) at Alicante or neighbourhood, and (3) in Algeria, where the ship would act as an hotel for all those who wished to use it in that capacity. The first party would, it was expected, break up into two chief sections: those who would alight at Cadiz and rejoin the ship at Alicante, and those who would rejoin the ship at Gibraltar. The scale of charges was given, and it was requested that applications for berths be at once made to Mr. Thomas Frid Maunder, 26, Martin's-lane, Cannon-street, E.C. The entire party would, from the arrangements made, have the opportunity of visiting Gibraltar and Lisbon. The latter port would, however, only be visited in case it was quite free from plague infection. Mr. Maunder emphasised that these arrangements would necessarily fall through unless a sufficient number of passages had been definitely engaged on or before Jan. 31, immediately after which date they must close their contract with the Royal Mail Steamship Company. If they carried out the proposed arrangements, he thought they would be able to organise a very successful and very cheap expedition to observe the eclipse.

Father Cortie presented the eighth report of the Solar Section, which dealt in detail with the sun-spots observed during the year 1898.

Slides to illustrate the great spot of September, 1898, of drawings made by Mr. Astbury, and at Stonyhurst, were thrown upon the screen.

Father Cortie said that now that we had almost reached the time of the minimum of solar spots, observers of the sun might very profitably turn their attention to observing the solar surface, and the wonderful changes that took place upon it, even at times of minimum. It was only rarely that the granulated structure could be seen, when the conditions for observing were exceptionally good. Generally the sun's surface appeared to be mottled, but when the seeing was above the average the bright mottling was broken up into distinct grains, as if handfuls of rice had been scattered over the surface. In the spectroscope on such occasions he had seen the spectrum crossed lengthways by a succession of light and dark lines, as if the dark spaces of the réseau were miniature spots. Then, again, there was the subject of "veiled spots," which, so far as he was aware, had only been studied by Trouvelot and at Stonyhurst. These "veiled spots" differed from the "penumbral markings," which sometimes persisted for several days in the neighbourhood of a spot group, and were either the first beginnings or the remains of a spot group before it became merged in the photosphere. The "veiled spots" were continually changing. A series of slides was thrown upon the screen from the Stonyhurst drawings, illustrating the "veiled spots," and showing their rapid developments. The genesis of the "blurred patches" in M. Janssen's photographs of the solar surface was most probably due to the change of "veiled spots" from the form in which they first appeared, round and perfectly distinct, until they became diffused, and extended over a larger area. These changes took place in a very few minutes. One slide exhibited the change as taking place in four minutes. The "veiled spots" were best seen in the early morning, before the telescope had become heated. A series of M. Janssen's photographs were then shown, to illustrate the granulated structure of the solar surface, the dark network or réseau, and the blurred patches. In conclusion, he would wish to call the attention of observers of the Solar Section to the remarks made by the President in his inaugural address for the present session as to the drawing up of observations. Frequently drawings were sent on half-sheets of notepaper, and the drawings were mixed up with descriptive matter. He would suggest that all drawings should be made upon a separate sheet of drawing-paper of the size of the *Journal*, and should bear upon them the date and time of observation, the observer's name, and the scale—so many inches or millimètres to the solar diameter. Enlarged drawings were preferable to those on a small scale. The descriptions, notes, and measurement of positions should be on paper of ordinary foolscap size, unless observers had printed forms for this purpose.

Mr. Maunder showed a number of slides from negatives taken at the Royal Observatory, Greenwich, illustrating the life-history of the great group of spots of September, 1898, during its second and third apparitions—viz., those beginning September 3 and September 30. Mr. Maunder wished to take the opportunity afforded by the presentation of the admirable report Father Cortie had made on the work of the Solar Section, to point out a rather curious circumstance with regard to the solar spots of 1897 and 1898. Directing attention to a diagram, Mr. Maunder said that in 1874 the mean spotted area was about 1,400 millionths, or one in 700 of the surface of the visible hemisphere of the sun. In the following years it declined rapidly, and in 1878 it had come nearly to zero. From 1879 it increased very rapidly indeed until 1883, each successive year showing a spotted area

very greatly in excess of the preceding one. Then from 1883 it came down somewhat more gradually until they got to the next minimum in 1888, 1889, and 1890. Then there was a straight run up to the time of maximum in 1893. From 1893 to 1896 there was just as rapid a decline, but in 1897 there was a check; and the mean area for 1897 was practically the same as for 1896; but in 1898 the fall was resumed, and in 1899 the areas still continued to rapidly decrease. But in 1897, when there was this curious check in the diminution of the sunspot area, there was at the same time a curious alteration in the locality in which the spots were seen. In 1874, when the record commenced, the spots were mostly in latitude 10°. Then they approached the Equator somewhat, until just before the time of minimum, they found the spots in latitude 7°. Then at the actual minimum, and just before the rise towards maximum began, there was an immense change in the latitude of the spots, and their mean position was in latitude 22°. From that time forward the mean latitude of the spots began to shift towards the Equator until, at the time they had most spots, they found the mean latitude was about 14°, and the latitude went on decreasing again until, just a little before they reached the spot minimum of 1889, they obtained the minimum of latitude at about 7°. The same process was repeated in this present cycle. There was a rapid run up to 21° latitude at the time of minimum in 1889, and before the increase in area began, followed by a steady movement towards the Equator as maximum was approached, and the mean latitude at the maximum of 1893, like that of the maximum of 1883, was about 14°. For three years there was very little change in the latitude; then in 1897, whilst the spotted area was abnormally maintaining its extent instead of diminishing, there was a most astonishing change in the latitude—a drop, in fact, to 8°, as if the minimum were already reached. This seems to have been due to the occurrence of several great groups in very low latitudes, close to the Equator, which was not at all usual at that period of the sunspot cycle. In 1898, however, there seemed to have been a return very nearly to the normal state of things, both as to the mean area of the spots and their latitude, and it reproduced in both particulars very nearly the state of things observed in 1886, so that if the present cycle went on according to the precedent shown in the last cycle, they might expect the dead minimum of the present sunspot cycle would follow about the middle of 1901.

Mr. Newbegin said the groups shown took him back to old times, for he had the pleasure of bringing some of them to the Association, and it was a great gratification to look over them again. The granulation of the sun shown by M. Janssen's photographs was of a most striking character, being only seen at intervals during a long period of observation. There was one question he wished to ask, more particularly for the sake of finding out whether he had been misled or taken in, or whether other observers had seen the same thing. He had on two or three occasions detected in the penumbra of a sunspot what he might call the weatherhead effect—prismatic colours forming a section of a cycle something like the little rainbows seen when bad weather was about, commonly called weatherheads. On two or three occasions he had seen this effect. The colours seem to belong to the sun, because they moved with the spot as it moved in the polariser. He wished to know if anyone else had seen the same phenomena.

Mr. Thwaites said he had never really observed prismatic colours as mentioned by Mr. Newbegin. He had not used a polarising eyepiece, except occasionally with a friend's telescope. The solar eyepiece he generally observed with was formed of two prisms of slight angle, which reflected the image from their outer surfaces, and did not give colour. Occasionally he had seen colour on the sun, but he had satisfied himself it had been due to want of focus. He had seen what some had called the "rice grains," but on very rare occasions—perhaps once or twice in a year, at the times of very best definition, and then only for a very short time. He had also noticed the areas of confusion—bad focus as it were of portions of the disc—which had been referred to, and was much struck with their appearance. They presented a marked difference to the other portions of the field, which were sharply defined.

Mr. Evershed asked Father Cortie if he had studied the solar surface with monochromatic light. He himself had recently taken many photographs with monochromatic "K" light. He could not say for certain he had got veiled spots, but he had obtained very curious markings, evidently very much larger than the veiled spots. Occasionally he got a perfectly straight dusky marking, apparently radiating from a disturbed region.

Mr. Adams asked how much of the peculiar solar grain on Father Cortie's photographs were due to solar granulation, and how much to the ground glass. He did not recognise the usual appearance of the solar surface in these photographs.

The President inquired whether Father Cortie had seen any colour in the sunspots. On one occasion only had he himself seen colour, and that was just as a bridge was forming, and that piece of the bridge, extending about one-third of the way across the nucleus, was a very bright red. He tried a Dawes eyepiece, a first-surface reflecting prism, and a polarising eyepiece, and the colour was the same in all of them. It was a very remarkable experience. Another question he wished to ask Father Cortie was: What form of eyepiece he, on the whole, recommended for direct visual observation of the sun? Personally, he had rather a partiality for the Dawes eyepiece; but Father Cortie had had very large experience, and members present would doubtless be glad to have his views upon the matter.

Father Cortie, in reply, said he had not had much experience in observing directly—it was mostly by projection that he had observed. The eyepiece he had used, and found to be excellent as long as it lasted, was one made by Mr. Hilger, and described by him in the *Monthly Notices*, R.A.S., some years ago—a prism partially of glass and partially of Canada balsam; but he found it difficult to keep the latter without air-bubbles getting in; otherwise, it gave most magnificent definition upon the solar surface. He was now thinking of getting a polarising eyepiece constructed, because many observers seemed to prefer that form. With regard to the other question of the President, the red veils in spots were frequently seen, at times of maximum, by projection on the drawing-board. Once at Stonyhurst they had seen a yellow veil corresponding to the wave-length of D^3. With reference to the other colours Mr. Newbegin and Mr. Thwaites referred to, he had never seen those, unless, indeed, they were caused by the chromatism of the telescope used. Employing a very high power for projection upon a drawing-board, they would see a coloured fringe round the spots, due to the chromatism of the object-glass, and not to anything on the surface of the sun. In reference to Mr. Adams's question, he reminded that gentleman that the illustrations were not photographs, but drawings on ground glass.

The President said he happened to have a special solar eyepiece which was made by the late Mr. Thomas Cooke for the late Rev. W. R. Dawes, some thirty years ago. He found this a particularly useful eyepiece, if it was desired to take micrometric observations of the sun. It consisted of an ordinary first surface, reflecting prism, the rays from which fell on a second first surface reflecting prism, so that the light was reduced enormously; not only so, but the image was exactly the same as if seen through the telescope direct. The definition did not appear to be at all marred by the double reflection. Between the two prisms was a coloured graduated wedge which could be used to further reduce the light. So far as he knew, it was the only such eyepiece ever made. Mr. Dawes read a paper upon it before the Royal Astronomical Society in the late "sixties" or early "seventies," but speaking from memory he could not give the exact date.*

Mr. Mark Wicks said he watched the progress of the large group of spots across the sun's disc in September, 1898, and had splendid seeing by the aid of a specially-designed apparatus attached to his 4in. Gregorian, which he described. The amount of detail seen was such that the photographs of the same group of spots taken at Greenwich, which had been thrown upon the screen, seemed to him very disappointing, as he assumed that a much larger ins'rument than his was used there.

Mr. Goodacre, the director of the Lunar Section, presented a preliminary report regarding the recent lunar eclipse, stating that the reports already received from twelve members unanimously expressed the opinion that the eclipse must be regarded as a bright one, and that it bore a great resemblance to that of December 27, 1898. At the time of the greatest phase the shadow was not dense enough to hide any of the larger formations, either ring plains or seas. A few occultations occurred.

Mr. J. Milton Offord exhibited a series of twelve lantern slides from photographs of the recent lunar eclipse, showing the progress of the earth's shadow at intervals of a quarter of an hour. The telescope employed was a 12¼in. reflector, the lunar image being enlarged to over 2in. diameter by a negative lens. At the time of greatest obscuration, the small portion of the moon remaining was readily photographed. In addition to the series on an enlarged scale, Mr. Offord also showed two photographs taken near the time of central eclipse, to which exposures amounting to 600 times the normal for the full moon had been given; these negatives exhibit most of the seas on the eclipsed portion of the disc, nearly the whole of the moon being visible, the light gradually fading away as the deeper parts of the shadow were reached. When these photographs were taken the limb of the moon appeared lighter than the centre to the naked eye, an optical illusion arising from the darkness of the surrounding sky.

The meeting adjourned at 7 p.m.

* The Rev. W. R. Dawes' paper was read before the Royal Astronomical Society in 1865, and will be found in the *Monthly Notices*, Vol. XXV. p. 218.—W. H. M.

SCIENTIFIC NEWS.

It is somewhat satisfactory to learn that some of the prizes of the Paris Academy of Sciences have been awarded to foreigners. Mr. W. R. Brooks receives the Lalande prize for his discoveries in connection with comets, and M. Nyrén, of Pulkowa, is awarded the Valz prize for his work in sidereal astronomy. The Arago medal was awarded to Sir G. G. Stokes, on the occasion of his jubilee at Cambridge University.

The Wilde prize is given to Dr. P. Zeeman, for his important discoveries of the relations between the magnetic field and the nature of light rays.

In the section of Mechanics the prize of 6,000 francs is awarded to M. Bailles, for his treatise on the geometry of indicator diagrams; and the Plumey prize to M. Bonjour, for inventions in connection with the steam-engine.

The Bréant prize for a method of treating Asiatic cholera has not been awarded, but the sum accummulated (6,000 francs) has been divided between three investigators of the pathogeny and pathology of tetanus.

Sir James Paget, Bart., D.C.L., LL.D., F.R.S, who died on Saturday last, was one of the most distinguished surgeons of this century. He was born at Great Yarmouth on Jan. 11, 1814, and studied at St. Bartholomew's, rising steadily in his profession until he obtained the highest honours. He was elected a member of the Royal College of Surgeons in 1836, and a Fellow in 1843, and was from 1847 to 1852 professor of surgery and anatomy there. In 1865 he became a member of the council, was appointed president of the college in 1875, and Bradshaw lecturer in 1882. Among other positions he held were those of Serjeant-Surgeon to the Queen, Surgeon to the Prince of Wales, and consulting surgeon to St. Bartholomew's Hospital. For many years he was a member of the Senate of the University of London, and in 1884 he became Vice-Chancellor. Honorary degrees, in recognition of his high professional attainments, were showered upon him by Oxford, Cambridge, and Edinburgh. In the profession he was perhaps more highly regarded than by the general public. His published lectures on surgical pathology brought him world-wide fame; and those, as well as his "Clinical Lectures and Essays," became standard works. He was created a baronet in 1871.

Mr. James Dens, engineer of the Clyde Trust, died suddenly last week from heart disease, at the age of seventy-two years. After a period of railway service, in 1869 he succeeded Mr. Andrew Duncan as engineer to the Clyde Trust, and all the great improvements that have been made recently on the Clyde were directed by him. The most important of the structural improvements made under Mr. Dens's direction were the Princess Dock and the graving dock at Govan.

The death is reported from Berlin of Prof. Karl Rammelsberg, the well-known mineralogist, and Professor of Inorganic Chemistry in the University of Berlin, aged eighty-seven.

To students of meteorology, the following note on barometric pressure may be suggestive. Mr. G. J. Symons, F.R.S., writes:—Inasmuch as a barometer on Hampstead Heath would read considerably (nearly ½in.) lower than one on London Bridge, meteorologists have long adopted the plan of correcting the readings at any station to what they would have been if placed at the level of the sea. The record here (Camden-square) now covers more than 40 years, but in that long period the pressure has been only three times lower than this afternoon, Dec. 29; therefore, the following few figures will be of interest. Minima of barometric pressure reduced to sea level:—1872, Jan. 24, 4.47 a.m., 28·332in.; 1876, Dec. 4, 11 a.m., 28·364in.; 1886, Dec. 9, 4.45 a.m., 28·295in.; 1899, Dec. 29, 5 p.m., 28·427in.

The "juvenile" lectures at the Royal Institution delivered by Mr. C. Vernon Boys, F.R.S., commenced with some elementary facts which, however, are not always remembered by the "juveniles" who attend the Christmas lectures. The experiments, for the most part, were as elementary as the principles they were meant to illustrate. The law that a liquid finds its own level led to an explanation of the principle of the spirit level and the delicacy of the work it

did. Pressure was illustrated by pouring varying quantities of water into vessels of different shapes, to show that the pressure did not depend upon the shape of the vessel but upon the depth of the liquid from the top. That liquids were of different densities was shown by a small quantity of one balancing a great quantity of another, by a lighter fluid being made to float on a heavier, and by an egg being dropped into some liquids in which it sank, and into others on which it floated. One of the most interesting experiments in this connection illustrated the testing of diamonds, emeralds, sapphire, ruby, and topaz, which sank or floated respectively, according to their genuineness or spuriousness. That air had weight was shown by sending up a small balloon; that its weight might be decreased was shown by heating the air within the balloon. The hydraulic press and the hydraulic engine were explained, with the view of showing the enormous pressure exerted by water, a practical proof of which was given by the breaking under the press of an iron bar. A diagram made the causes of the circulation of hot water for baths and heating purposes clear.

At the Royal Institution on Jan. 16 Prof. E. Ray Lankester, M.A., F.R.S., commences a course of twelve lectures on "The Structure and Classification of Fishes." On Jan. 18 Mr. W. H. R. Rivers, M.D., will commence a series of three lectures on "The Senses of Primitive Man."

Dr. E. T. Jones has been appointed professor of physics in the University College of North Wales in succession to Prof. A. Gray, F.R.S. The Drapers' Company has made the college a grant of £200 annually for three years towards the maintenance of the department of electrical engineering, pending its permanent establishment.

The London Technical Education Committee have arranged for a second conference of science teachers to be held during the Christmas vacation. Meetings will be held on Jan. 10 and 11, 1900. On the first day the meeting will be held at the Imperial Institute, under the presidency of Sir John Lubbock (now created a peer) in the morning, and of Sir Henry Roscoe in the afternoon. The second day's proceedings will take place at the Shoreditch Technical Institute, Hoxton. Addresses will be delivered on "Teaching of Botany in Schools," by Prof. L. C. Miall, F.R.S., and "Object Lessons in Botany," by Miss Von Wyss. Prof. Armstrong will lecture on "Juvenile Research," and Prof. Hutchinson will read a paper on "Teaching of Natural History in Schools." Addresses will also be given on "Object Lessons in Natural History," by Mr. J. W. Tutt; "Metal Work as a Form of Manual Instruction in Schools," by Prof. W. Ripper. Free admission will be granted to as many teachers as the conference rooms will accommodate.

At a recent meeting of the Physical Society, Prof. W. E. Dalby exhibited a friction dynamometer in which the torque to be measured produces a twist in a spiral spring, the amount of which has to be determined. On the shaft of the apparatus, side by side, are two pulleys, one keyed to the shaft, and the other fastened to the end of the spring. The lead of one pulley upon the other, therefore, measures the twist. Two other pulleys are mounted upon a slide, and are joined up to the first ones by means of a continuous band similar to a Weston's differential pulley block. When the shaft is at rest the two pulleys on the slide are touching, but any motion of the shaft produces a twist in the spring, and therefore a lead of one of the shaft pulleys on the other. This produces a separation of the slide pulleys which is proportional to the lead, and therefore to the torque, and so, from a knowledge of the constants of the dynamometer and its number of revolutions per second, the power transmitted is at once determined.

At the Royal Victoria Hall, Waterloo Bridge-road, on Jan. 16, a lecture will be delivered by Mrs. Lemon on "Birds at Home and Abroad," and, on Jan. 23, Mr. A. Seward, F.R.S., will lecture on "Plants of Long Ago." On Jan. 30, Mr. F. W. Rudler is to lecture on "The Fathers of Geology."

It is estimated that the Great Salt Lake, Utah, U.S.A., contains about 400 million tons of salt, and although about 42,000 tons of commercial salt are removed annually, it appears that something like 14,000 years must elapse before the water of the Lake will become like ordinary sea-water. The evaporation is greater than the rainfall can supply, and it is possible that some means of utilising the salt may be devised. Similar ideas have been put forward with regard to the Dead Sea. The question is, Can the schemes be made commercially profitable?

One of the latest ideas in submarine boats is that of an engineer named Rogers. It is a telescopic boat, so that when the after part is drawn in or pushed out by means of hydraulic mechanism provided for the purpose, her displacement is altered, and so she rises or sinks as required. She is fitted for the discharge of Whitehead torpedoes, and has another peculiarity, in that her conning-tower is, so to speak, a complete boat in itself. Should any untoward accident befall the vessel, all the captain and his crew, who are together in the conning-tower, have to do is to leave the sinking ship. They disengage the tower from the foundering hull and float away, perchance to safety. It is not quite clear about the alteration of displacement, and it is not stated that the boat has been tried on the scale of twelve inches to the foot.

USEFUL AND SCIENTIFIC NOTES.

CALVERT'S MECHANICS' ALMANACK for 1900 is the twenty-seventh year of publication (London: John Heywood), and contains many readable and valuable notes, and is what it purports to be, a "workshop companion."

THE imports of coal, now so largely carried to Hull by the various railway companies, will, it is expected, this year exceed any of its predecessors. The total entry of coal for the year 1898 reached 3,458,418 tons, against 2,655,744 tons in 1897, 2,420,416 tons in 1896, and 2,190,016 tons in 1895. Up to the close of November in the present year the imports had reached 3,248,160 tons, compared with 3,142,836 tons in 1898, an increase of no less than 105,324 tons. During the month of December, 1898, 316,656 tons were sent, and as only 210,328 tons are required to be sent during the present month to reach last year's tonnage, it is but fair to assume that the total imported will be reached, if not exceeded.

A COMPLETE electric search-light apparatus is about to be added to the New York Fire Brigade. It will be mounted on wheels, and will accompany the brigade to fires. Its purpose will be to light up dark parts of the street, and aid firemen in laying hose, setting ladders, or other work. The machine will resemble a fire-engine in general appearance, and will use a similar boiler, but in place of the pumping machinery the engine will drive a dynamo, which will supply the lighting currents for the search-lights. There will be two search-lights, each with an 18in. projecting lens, and these will be carried on a platform behind the driver's seat. They can be used either from the platform, or removed and carried to any convenient place near by, their connection with the dynamo being kept by means of flexible cables.

THE power house of the Niagara Falls Hydraulic Power Company has recently received a new machine designed to give 5,000 ampères at 175 volts. This machine, which is for electrolytic work, has two commutators. The two sets of brushes are connected in parallel with each other. The load on the machine is divided between the two commutators, or rather between the two armature windings by an ingenious arrangement of varying the lead of one of the other set of brushes. This is done by means of ratchet gear in one side of the field frame. These ratchet-wheels work a brush-rocking apparatus by means of spur-gearing. The cross-shaft, on which the ratchets are placed, can either be worked as a whole, in which case the brushes on the commutators move together, or it can be split into two, so that one set may be worked separately to divide the load evenly between the commutators.

A SYSTEM of electric train lighting in use on the Paris, Lyons, and Mediterranean Railway has a dynamo provided on each carriage, arranged with its axis parallel to the rails. A friction wheel on a prolongation of this axis is pressed against one side of a running wheel. In this way the motion of the wheel is transmitted to the dynamo. Between the dynamo and the axle which drives it a friction clutch is provided, consisting of carbon brake blocks pressing on a bronze disc. The pressure of these carbons on the disc is such that slipping only commences when a current of 28 ampères at about 16 volts is being generated by the dynamo. This corresponds to a speed of about 30 miles per hour. At any higher speed slipping occurs, the idea being that the speed of the dynamo shall not increase, as an increased speed would also correspond to an increased torque. The dynamo is used to charge a battery of accumulators, which supply light to the train when it is stationary or only going at a slow speed.

LETTERS TO THE EDITOR.

[*We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.*]

All communications should be addressed to the EDITOR *of the* ENGLISH MECHANIC, *332, Strand, W.C.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks; a vice from whence great inconveniences derive their original."
—*Montaigne's Essays.*

VARIABLE STAR OBSERVATIONS, DECEMBER, 1899.

[43159.]—S CASSIOPEIÆ has varied but little from 12·5 magnitude during the ten months January to October, 1899, and was often so faint as to be near the limit of vision with this telescope. A decided rise set in on October 30, and on December 27 the star was 8·7 magnitude, having risen four magnitudes in two months.

U Orionis passed a minimum, 11·8 magnitude, November 26. The interval since the previous minimum, November 18, 1898, was 373 days. The rise will probably be rapid, and this star will soon become an easy object.

R Lyncis has been gradually going down for the last five months, and is now a very faint star, 12·0 magnitude. The minimum will probably occur about the end of January, 1900, so that for the next two or three months this variable will be a very difficult object.

S Ursæ Majoris passed a minimum, 12·2 magnitude, October 30. The interval since the previous minimum, April 7, was 206 days. The rise has been rapid, and it was observed 8·5 magnitude December 27.

R Draconis passed a minimum, 13·3 magnitude, November 26, when it was a very faint point, and near the limit of vision with this telescope, this being a very faint minimum. The interval since the previous minimum, February 27, was 272 days. The star is now brightening, and was observed 10·6 magnitude, December 25.

The instrument used was the 6·4in. equatorial refractor. Weather was very unfavourable. Observations were made on ten nights, on some of which the cold was so intense that the dome was moved with great difficulty, and the equatorial clock ceased to work. C. E. Peek.

Rousdon Observatory, Lyme Regis.

THE LUNAR ECLIPSE OF DEC. 16, 1899.

[43160.]—THE morning of the 16th was fine, but the afternoon and early evening promised badly. However, at about eight o'clock the sky showed signs of clearing, and just before ten the clouds drifted away, and left the moon soaring in a clear sky.

I took my stand at the telescope at 10h. 45m., twelve minutes after the calculated time of first contact with the pneumbra:—

(1) 10h. 45m. The sky is beautifully clear, and the atmosphere chilly. With the telescope there seems to be a darkening on the limb of the moon between the positions of the craters Lavoisier and Gérard. It extends some little distance into the disc.

(2) 10h. 53m. Appearance much the same as in observation (1). I cannot decide whether the darkening is due to pneumbra or local causes. [After-observations lean to the side of the penumbra.]

(3) 11h. 5m. Appearance very similar to (1) and (2).

(4) 11h. 18m. The penumbra now extends into the bright region between Mairan and the Sinus Iridum, and there is a toning south of Grimaldi not previously noticed.

(5) 11h. 28m. The darkening first noticed [observation (1)] has now deepened, and is nearly as dark as the seas next it. It seems to have extended farther north, but it is here very faint. It can be traced in a southerly direction to a point 5° or 6° south of Grimaldi. The penumbra is easily perceptible to the naked eye.

(6) 11h. 38m. The penumbra is now plain to the naked eye on the N.E. limb of the moon. In the telescope it is visible over the eastern half of the disc, and can be traced as far westward as the Sea of Serenity on the north and to ray system of Tycho on the south. This crater and the bright region around it, however, are not at all affected by the penumbra.

(7) . . . . The surface east and south-east of Aristarchus is now much darkened.

(8) 11h. 46m. I should say the first contact with

the shadow occurred at about 11h. 45m. by my watch, set correctly to G.M.T. in the morning. The penumbra shaded off so completely into the shadow that it was very difficult to recognise the shadow until well on the disc.

(9) 11h. 52½m. The edge of the shadow passes through the eastern part of Sinus Iridum, and thence to a point 3° S. of southern end of Grimaldi. A line of light runs along eclipsed limb, widening out near Grimaldi. The shadow is very dark, almost black. Already a perceptible difference in the light received by terrestrial objects from the moon is noticed.

(10) 12h. 4m. Illuminated limb still noticed.

(11) 12h. 13m. The shadow-edge is very near the eastern border of Mare Serenitatis. Farther south there is a "bite" or "bay" in the shadow, evidently caused by the high ground of the Apennines. The portion of the shadow near the limb is lighter than the edge, and the limb is lighter still. The brightest portion of the shadow is on the limb near N. end of shadow.

(12) 12h. 34½m. Edge of shadow touched eastern ramparts of Tycho. On the limb of the moon, slightly E. of N. point, is a bright orange strip, shading off and disappearing a little north of east. The limb becomes bright again further on, but is not so bright as in the north.

(13) 12h. 41m. The "seas" are now plainly visible with low power of telescope. The strip noted in observation (12) has increased greatly, and is ruddier than before. The edge of the shadow is lighter in colour, and is now only of a dark grey tint.

(14) 12h. 55m. The edge of the shadow passes through Mare Fœcunditatis. The region round Mare Crisium, although in the shadow, is only of a golden yellow colour. This tract passes north and diminishes in breadth and deepens in colour to a beautiful deep coppery hue as it approaches the patch noted in observation (1).

(15) 13h. 13m. Only a narrow crescent left, running out along the S.E. limb as a narrow strip of half-tone. The lightest portion of the shadow is that around Mare Crisium. It passes north, becoming ruddier in colour on that strip N. of Maria Serenitatis and Imbrium. The stars, which have been gradually becoming brighter and more numerous, now shine brilliantly. Orion and Sirius to the south, Aldebaran, with the Hyades and Pleiades to the west, and β and ζ Tauri respectively north and south of the lunar disc, form a splendid framework to the imposing picture. Add to this the curious appearance of the moon, with its luminous crescent and copper-coloured disc, and the flight of some bright meteors, and one gets an idea of the beauty of the celestial phenomenon.

(16) 13h. 30m. The light received from the moon is just sufficient to throw a shadow on the snow covering the ground when the hand is held close to its surface. The successive appearances of the shadows cast on the snow have well shown the progressive diminution of the light received from the lunar orb.

(17) 13h. 50m. The crescent has increased, and its points are extended along the limb into the shadowed portion as two half-shaded strips or horns, the eastern one of which is the brighter. The portion of the moon diametrically opposite the middle of the bright crescent is the ruddiest portion in the shadow.

(18) 13h. 58m. Shadow becoming darker. The "seas" are now not so easily distinguished.

(19) 14h. 11m. Edge of shadow passes a little N. of the crater Ball. Aristarchus can be discerned within the shadow.

(20) 14h. 20m. The shadow is now much darker, its outer portion being of a dark drab tint. Aristarchus can be seen touching inner edge of the shadow.

(21) 14h. 34m. The shadow is very dark, and no *maria* are visible in it. Its edge passes through the north-western borders of the Mare Vaporum.

(22) 13h. 42m. There seems to be a dark, sea-green tint in the shadow (this has been before suspected). The shadow fades away through a belt of faint penumbra 10° or 12° wide, the rest of the moon not seeming to be affected by it.

(23) 15h. 4m. Shadow-edge touches N.W. ramparts of Mare Crisium.

(24) 15h. 7m. Observed last contact with shadow. Calculated time, 15h. 7·2m. Estimated, 56° N. towards W. Calculated, 59°.

(25) 15h. 11m. The penumbra is very strong N W. of Mare Crisium, and extends to the western borders of the Maria Tranquillitatis, Fœcunditatis, Serenitatis, and Frigoris.

(26) 15h. 20m. Penumbra still visible.

Remarks.—The Penumbra: This was first noticed at 10h. 45m. During its progress over the moon the region near the positions of the craters Lavoisier and Gerard seemed peculiarly affected by it. At first in avoided the Polar regions [obs. (5)], especially the N. Pole.

The Shadow.—The shadow at ingress was ill-defined. It afterwards became more clearly cut, but just before passing off again became diffuse, though not so much so as at ingress. The last contact was much more easily seen than the first.

The *colour* of the shadow was noted first as "very dark, almost black" (11h. 52½m.). At 12h. 41m. the colour of the shadow edge was dark grey. The interior of the shadow became very light-coloured at times, and was noted as "golden yellow" a 12h. 55m. The tint of the shadow then deepened, becoming dark drab and nearly black again, when it was thought to show at times a dark green tint. Instrument in use 2½in. refractor; powers 15—50.

Leicester, Jan. 1. A. King.

THE LUNAR ECLIPSE.

[43161.]—THE lunar eclipse was splendidly seen in Keswick. I was much struck by the ease with which the Leibnitz mountains could be seen standing out on the uneclipsed edge at about 2 a.m. Dec. 17. Did any other observer notice this? I had never seen them before, and was not looking for them. My instrument is an 8½in. reflector.

Eccleshall. A. C. Allen.

LUNAR SEAS AND RAYS.

[43162.]—I SEE a subject introduced in *Knowledge* November and December numbers which I would like to see discussed in "Ours," as I think it would interest several of our readers. Mr. Tepper suggests that the lunar seas are covered with a coating of carbon dust, the remains of the plants and animals of the moon which lived on it in former time before the moon became a *dead world*. Several questions may be asked just here, and what can be known should be made as certain as the nature of the case admits. I ask, first, What reason have we to think that the moon had living organisms of any kind on it in the past? Having no atmosphere and no water, it is not easy to see how plants or animals could exist; and yet I think that the time may have existed when our moon had both water and an atmosphere. Will your readers tell us what they think on this subject? The difficulty would be less than it is at present if the moon's rotation period was ever shorter than at present—that is, if it rotated on an axis several times in a lunar month; but the earth's attraction, which keeps the same side earthward now, would have done so in the past, for it is thought that G. Darwin has proved that the moon was at one time very near the earth, and at that time the attraction of the earth on the nearer half of the moon must have been greater than now, and its tendency to keep the same side earthward would have been greater than at present. Nevertheless, I have long thought that some fine loose powder or something like snow (possibly carbon dust) does exist on the moon's surface, in some places at least.

I think we have not given sufficient thought to the fact that the moon has no atmosphere, and that as a consequence all the meteoric matter which falls on the moon will reach its surface. Many tons of cosmic dust fall on the earth every year, but it is burnt up in rushing through our atmosphere, and never reaches the earth's surface; it is only very large meteors which reach the earth's surface. In the moon all will fall on the surface, and it may remain undisturbed until other meteors fall on it or sweep through it, scattering the dust on each side of its track. I think the fall of large meteors vertically on the moon into its dust-covered surface, would scatter the light matter from beneath and around it, and form the ring-plains, and the so-called craters, with radiating streaks, like Copernicus, Kepler, and Tycho, may have come into existence in this manner. And the meteors, passing nearly horizontally across the moon, would be likely to produce those rays which run parallel with each other, and do not diverge as if radiating from a centre. Such rays as the two which pass from near Tycho to Bullialdus, and the great sweep from Kircher to Lexell, in which the rays run parallel to each other are good examples.

There are many other features, which, I think, may be explained by this meteoric view, and I think Mr. Tepper's view of animal and vegetable life is not inconsistent with this view. I should like to see it discussed. A. Elvins.

ANCIENT ASTRONOMICAL CHRONOLOGY.

[43163.]—IT was not until after I sent you my letter on the supposed Chinese conjunction of planets that I met with Prof. M'Fairland's article on "Ancient Eclipses and Chronology," in *Popular Astronomy* for December, 1899. It does not deal with Chinese observations; but I think it will be found well worthy of the perusal of those who repose any faith in these early astronomical notices —which seldom came from the pen of an astronomer. One of the great supposed landmarks is thought to be the eclipse which Thales predicted, and which put an end to a battle between two Oriental monarchs. When did it occur? I gave the dates from Prof. M'Farland's article: Volney B.C. 623, Baily Sept. 30 B.C. 610, Ideler and Grote B.C. 610, Oltmann B.C. 610, Bayer and others B.C. 603, Usher B.C. 601, Lardner B.C. 597, Sir G. B. Airy May 28 B.C. 585, Grant (citing Cicero and Pliny) B.C. 585, Rawlinson B.C. 584, Bosanquet B.C. 583, Scaliger Oct. 1 B.C. 583, Clemens Alexandrinus B.C. 579. The difference between the extremes is 46 years, and there are strong authorities for both B.C. 610 and B.C. 585.

The professor's conclusion is that "there is no new light from old eclipses." The truth seems to be that in hardly any instance is the record definite enough to fix the date even approximately. The dates given are found by computing backwards from the data which are generally accepted at the date of the computation, and then it is assumed that the early eclipse proves the accuracy of our present theories. The same thing is true of early conjunctions. It may be that early observations are not wholly useless, but they should evidently be treated in a much more critical spirit than hitherto. We should inquire what the original writer has actually said, or is reported to have said, if we do not possess a copy of his works, in which latter case we should also inquire into the probable accuracy of the reporter, and if we compute backwards we should also examine what amount of variation either in the year or in the season of the year would be consistent with the original account. Unless this amount of admissible variation is small, I do not think the records of past eclipses, conjunctions, &c., afford any proof that our present astronomical tables are shown to have held good for thousands of years past by comparing them with these records. W. H. S. Monck.

SOLAR SPOT OBSERVATIONS, DECEMBER, 1899.

[43164.]—THE accompanying observations may be of interest:—

1889.		h.	m.	Total Spots Recorded.	Groups of Spots.	Groups of Faculæ.	Air.	Remarks.
Nov.	26	2	30	1	1	1	1	Def. good
,,	28	2	0	1	†1	2	1	,,
Dec.	2	2	30	1	1	void	1	,,
,,	4	2	0	6	†2	1	1	,,
,,	8	2	0	4	2	2	1	,,
,,	10	0	45	void	—	1	2	Def. poor
,,	14	2	0	10	†3	1	2	Def. good; hazy
,,	16	1	45	11	3	2	1	Def. good
,,	24	0	15	void	—	1	2	Def. poor
,,	25	1	0	void	—	2	1	Def. excellent
,,	27	1	20	void	—	void	2	Def. poor
,,	30	1	0	4	1	void	1	Def. good
,,	31	0	40	1	1	void	1	Def. excellent

In the table, the daggers in the fourth column indicate that on those dates a fresh group of spots were appearing on the east limb of the sun. Air 1 is good; air 2, fair. On those dates omitted observations were precluded by unfavourable weather. It will be seen that there is a break from the 16th to the 24th, during which time there was not a gleam of sunshine here, a circumstance the more annoying as the groups then visible were the most interesting of those recorded during the month. The instrument in use is a 2·85in. achromatic, no spot being recorded unless distinctly seen with a power of 60, the projection method being used except when haze renders that method impracticable. Silverplume.

THE CONJUNCTION OF CHINESE PLANETS.

[43165.]—As Mr. Williams's work on Chinese comets is unknown to many of your readers, I ask space for a few more remarks as regards the alleged conjunction of planets. The reference to it occurs in his "Introductory Remarks," which deal with Chinese astronomy in a more general aspect. The passage regarding the conjunction (pp. viii., ix.) runs thus: "In the Chinese annals it is recorded that in the reign of Chuen Kuh, the grandson of Hwang-Tē, in the spring of the year on the first day of the first moon, a conjunction of the five planets occurred in Ying Shih. Ying Shih (or, as it is more usually denominated, Shih) is one of the 28 stellar divisions, determined by α, β, and other stars in Pegasus, extending north and south from Cygnus to Piscis Australis, and east and west 17°, and comprising part of our signs Capricornus and Aquarius. The Emperor Chuen Kuh is said to have reigned 78 years from B.C. 2513—2436, and to have died in his 97th year," and then follows what I have already quoted. I may remark that Mr. Williams refers to B.C. 2737 as the 60th year of the reign of Hwang-Tē, the grandfather of Chuen Kuh. Consequently, 183 years elapsed between the commencement of Hwang-Tē's reign in B.C. 2696 and that of his grandson Chuen Kuh in B.C. 2513, when the latter was only 18 years of age. Subsequently, I find Mr. Williams described the reign of Yaou as lasting

for 100 years (p. xi.), and I presume this 100 years' reign was one of the data by which the dates and accession and death of Chuen Kuh were arrived at. I do not think many of your readers will rely on this kind of chronology, and, assuming that Chuen Kuh was a real, not a mythical, character, I should be disposed to ascribe his reign to a latter date than B.C. 2440, so that none of the alleged conjunctions would fall within it.

I am no authority on Chinese chronology, and should be glad to have the opinions of those who are. But the first comet recorded by Mr. Williams appeared in B.C. 611, and it seems strange that if the Chinese astronomers were so well acquainted with the planets in B.C. 2440 they should not have recorded the appearance of any remarkable comet for more than 1800 years afterwards. It will be noted, too, that in the computed conjunctions the most conspicuous of the planets—Venus—is conspicuous by her absence.

My impression is that the real recorder of this conjunction is some astronomer who lived 1,500 or 2,000 later, and arrived at it by computation, and, accepting the historical theories then current as correct, placed it in the reign of Chuen Kuh, and though the alleged conjunction of five planets did not take place, he probably showed considerable knowledge of their periods in computing it. Supposing, for example, that he made an error of six hours in the period of Venus, he would be wrong as to her position by more than a month if the computations were carried back for 2000 years.

Such questions ought to be dealt with entirely from the scientific or evidential point of view. When the theological element is once introduced, some people will swallow anything that tells on one side, and others will swallow anything that has an opposite tendency. "Balaam's ass has been too conspicuous on both sides of the controversy" is the remark of the Rev. E. J. Hardy in his last publication. The ass was not always Balaam's.

W. H. S. Monck.

SOME CORRECTIONS—THE LEONIDS—BLUNDERS—ACETYLENE.

[43166.]—I SHOULD like, by your permission, to correct two or three little errors which appear in letter 43119 on page 425 in the issue dated Dec. 22. In par. 2, line 1, "a power of 80 on 6in." should read "a power of 80 on 3in." In line 5, same par., "penumbræ" should be "penumbral." And at the very commencement of the middle column, "12h. 30m." should be "13h. 30m."

Like "W. T. N." in letter 43124 on the same page, I am rather astonished that the theory now advocated to account for the non-appearance in any quantity of the Leonids last month has not been more publicly advertised before; and that Messrs. Jupiter and Saturn should have developed a meddlesome disposition within the last forty years far in excess of anything they have done before for some centuries past. So long ago as November, 1895, I mentioned in letter 38231, page 313, in the issue dated 22nd of that month, that, in spite of the dictum of "authorities" on the subject, I was tempted to predict that for two or three Novembers following there would be no striking display of Leonids. Not that I was thinking anything about Jupiter and Saturn in connection therewith; but I found it difficult to persuade myself that the vanguard of the swarm could extend so far in advance of the nucleus. If the familiar influence of gravitation is in operation amongst these particles, I should fancy their mutual tendency would be to coalesce rather than to become more diffuse. And that, therefore, if anything like the densest part of the swarm was passed through by the earth in November 1833, a part three months in advance of that was traversed in November, 1866, and their orbit was crossed six months in advance last November. Viewing things thus, and shunting Messrs. Jupiter and Saturn, I am tempted to predict the next really grand display for November 16-19, 1966, especially as I believe the moon will not then be obtrusive. I certainly hope to see a great many more Leonids next November than I did this last; but as to counting them by thousands—I will freely forego the last cypher. Their failure to then and thus appear will go very far towards corroborating the conclusions of Drs. Johnstone Stoney, and Downing.

Books are turned out at a furious rate nowadays, and, "cheap and nasty" many of them may be. But there is one book annually published which has found a place on my shelf for many years, and which it is extremely disquieting to find manifesting any signs of nastiness or—in other words — inaccuracy. I refer to the enlarged *Whitaker's Almanack*. Two days ago I bought that work for 1900, and your readers may judge of my astonishment when in reading its remarks on the prospective Leonid display of November next, I was told that at the otherwise most favourable time to watch for them—the morning of the 15th—"the moon will unfortunately be nearly full." (!!) (see page 683.) Why the book itself informs us on page 57 that at the time in question the moon must be at least something like 22½ days old, or about a day past "last quarter."

Although a few more days added to her age would doubtless be some advantage, it is pretty clear that the writer of the paragraph in question was confusing in his mind the state of things prevailing on the 15th of last month with celestial conditions of next mid-November. If this is "really too bad," what are we to think of the arrangement of things on the next page (634)? The second paragraph on that page gives a number of dates on which "large meteors should be particularly looked for." Some of these dates are printed in heavier type than are others. The explanation of the reason for this is omitted here, and clapped in as a sort of appendix to the article on "Telescopic Powers Necessary for Observing Celestial Objects" on the same page, with which it has just as much to do as I have with the financial condition of Tropical Venus. "Carelessness," of course, may be considered a satisfactory explanation for the whole; but the unfortunate thing about it is that when you *know* a book is unreliable in some places, you cannot trust it in others.

For this reason I should be very glad of a little information on the subjoined subject from some *practical* contributor to these pages—not from a book-worm. On page 665 of the said *Whitaker's Almanack* for 1900 it is stated in the paragraph on Acetylene that "It is found better, not to employ the naked carbide of calcium to yield the gas, but to saturate it with petroleum, or a mixture of tar and petroleum residues, &c." Have any of "ours" tried this experiment? If so, what improvement has been experienced? Is the ordinary refined table lamp petroleum the thing meant, and is the carbide to be simply dipped in this before being placed in the generator? And, what is the improvement? As to tar (coal tar, wood tar, or what?) one might think if lumps of calcium carbide were very thickly coated with that material, they would thereby be protected from the action of water altogether. Of course, I might find out something about it by personal experiment, only the said carbide is not by any means a nice thing to play with, and I know that the brotherhood of "Ours" is not churlish. William Godden.

SODOM DESTOYED BY THE LEONIDS.

[43167.]—MR. WENHAM may be assured that Genesis rightly describes the plain of Jordan as "well-watered everywhere, before the Lord destroyed Sodom and Gomorrah, like the garden of the Lord." The most fertile and populous part of Persia is about Tebriz, draining into the only known lake that is salter than that of Lot—the lake Urumia. Wherever fresh streams descend to the Dead Sea, as at Ain Jiddi—the Scriptural Engeddi—there is fertile land with abundance of date palms. All the barrenness is caused by salt—not by bitumen or sulphur, which belong to the strata. No account describes any salt strata; but at the south end there is a hill of salt some miles long called Jebel Esdoom, or "Sodom Hill," out of a cave in which a stream of brine flows. It seems to appear, like that near Biskara in Algeria, as if fallen from the sky. Before it arrived, the stream was doubtless fresh like that of Engeddi.

The story in Genesis implies that though five cities were destroyed for their wickedness, only two —Sodom and Gomorrah—were *buried*. The Lord "rained upon them burning stone and fire." The other three were merely ruined by the earthquake shock, and all inhabitants driven away or killed, except Lot and his two daughters in Zoar; but these dared not remain in the ruins lest another fall of sky should overwhelm them. They moved into a bomb-proof cavern, and believed themselves the only human beings left on the earth. Nothing that Mr. Wenham describes implies the neighbourhood was not populous 4,000 years ago, even if the sea was as salt as Lake Urumia. Those who have examined the deposits find them not so deep under the lake as in the Jordan valley north of Jericho. That would imply that before the catastrope, the lake was about 50 miles further north, and the site of the present lake being watered by streams flowing northward was eminently fertile: hence Genesis calls it "the vale of Siddim, which is the Salt Sea."

E. L. Garbett.

NEPTUNE—GREGORIAN, BINOCULARS.

[43168.]—REPLYING to "Neptune," my observation of his satellite was on Nov. 12, 1899, at 11 p.m. and Nov. 18 at midnight. The satellite was estimated to be at 250°, being roughly, and about 12" distant, but no great accuracy is claimed. I have no ephemeris of the satellite, so that observation is independent of knowing where to look. When "Neptune" says the satellite has not previously been seen with so small an aperture, he forgets his instance of Ward with 4·3in. My aperture had an area larger than this as to 30 to 18. Power used 300± on 5½in.

Replying to "Hippalus," as I have said, the Gregorian has the flatter field, but otherwise I have noted the defects "H." indicated; but perhaps my instrument is too small to bring them into prominence. He is right about my inquiry re John Bird. It appears, then, the history is a hoax played off on the B.A.A.

I think "Hippalus" will find the polished plate discs the best for specula. The cast ones are seldom well annealed, and the steam acting like springs, as he so well puts it, also like springs alter with temperature, and so no figure is maintainable. The polished plate is much freer from bubbles and is softer to work.

What is the best binocular that is procurable irrespective of price? I should like a power of about 6, and a large field but, above all, definition. Which is the best defining opera or field-glass in existence, even if with small field? I am sure this will interest many. Would a higher power than 6 be advisable or presumable?

I join "Hippalus" in his congratulations to the Editor upon the publication of such letters as those of "H." I hope "H." will keep his promise to deal with the flat question shortly. Ell Hay.

THE NEWTONIAN-GREGORIAN OF "ELL HAY."

[43169.]—IN letter 43111, Dec. 15, "Ell Hay" tells us that since he wrote (his) last letter he has "been busily comparing the performance of (his) telescope as a Gregorian and a Newtonian." His star tests given there were made, he again informs us, "in August last." In 42669, August 11, he said (we remember): "We can see double stars just as well with it as a Gregorian as with a Newtonian, and *vice versâ*, and *there is no perceptible difference in light*" (italics mine). Now, however, he says, referring to these August observations, that with stars forming light tests, the two forms performed equally *only* when (in his case) the Gregorian had 1in. greater aperture.

The equality of light in the two forms (which by the way, I strongly questioned when first mentioned) *was as his personal statement*, however, quite easily understood in the light of past letters—even in errors there must be a certain amount of consistency. The inversion of Jamin's tables is not without meaning in this sequel, neither are previous references to the well known fact that metallic reflections as well as others lose by close approach to normal incidence; although in these references both the theory and its application to the Gregorian were given contrary to the circumstances. *Now*, however, in order to multiply if possible his instances of what he considers disadvantageous comparisons for the Gregorian, he contradicts his former statement, so that in letter 43111 we are told (in reference, be it remembered, to these so-called "observations" in August last), that with a light test, the two forms of reflector were far from equal. (Contrast in this respect 42669 and 43111).

In the latter of these letters, we are also, as stated, informed that the comparisons given were made *since* (he) wrote his last letter, whereas, since the epoch he mentions (August) he has written at least twice, once on Sept. 8 (42783), and again since that date; in respect of which letter the Editor saw fit to deprive us of the pleasure of reading it, for in his notes on p. 193, Oct. 6, he remarked, "When you have learned good manners, we shall be disposed to give you another hearing." In this way are the first three paragraphs of letter 43111 disposed of; with the exception of his rather incomprehensible imputation of "animosity" to myself.

On the contrary, in so far as I am concerned, I do not remember having put myself to so much trouble to serve and oblige any correspondent as I have done in "E. H.'s" case, to which fact others, such as "Balolo," have drawn attention (see letter 42684, Aug. 18). Besides, while feeling myself unable to pass over some of "E. H.'s" misstatements, especially those in reference to γ^2 Andromedæ, which, as "Halley" the second, he has taken under his special jurisdiction, I was careful to add, in 42844, Sept. 22: "I criticise only statements, *never the writers of them*." "Animosity" must, I fear, be looked for elsewhere.

But, after all, are we to take the letters of "Ell Hay" seriously, especially when he asks for such information as the last par. of letter 43111 seeks for? Is it intended that we should look for any serious meaning—not to use the word "veracity" which "E. H." so ostentatiously uses elsewhere — in a "person" who pretends to have measured five times over the diameter of a speculum hole to within the *hundred-thousandth of an inch?*—this in actual measurement, remember, not in mere theoretical quantities such as I introduced in my computations.

The same kind of assertion is made in letter 42579. From the impossibility of perfect equality in all the rotational diameters of the said hole mentioned in 42516, as well as from want of any likelihood of perfect parallelism on the plane of measurement, the measures given are, I venture to say, from these causes alone, mere pretence.

The almost daily measurements of even much larger quantities under the microscope and my experience of measurements off the microscopic

slide force me to the conclusion that without perhaps such appliances as those used by Prof. Turner, of Oxford, and even those unfitted for this purpose, the numbers given by "Ell Hay" are purely mythical—a state of matters speaking little for the "veracity" of one who elsewhere ridicules fine measurements when they really come within the sphere of possibility. Besides, while questioning the reality of the above measurements, one may notice the rather subtile attempt in 42421 to lead me to give *present* measures for γ^2 Andromedæ, for, of course, those given in that letter, as *made by "E. H." himself at that date*, are more beyond the possibility of his execution at the time than the measures of others, at which, for the same reason, he scoffs in another place.

But finally, respecting any real possible value which "E. H.'s" comparisons may have, we must remember first that these comparisons were *not made* between two telescopes equally perfect in their kind (which is everything in such comparative trials), but between a Newtonian which had suffered from a certain disturbing cause—perforation of the mirror subsequently to figuring—and a Gregorian, which had from the same cause suffered at least ten times as much. As pointed out at p. 65, Sept. 1, the long equivalent focus given to the telescope by the action of the small speculum of the Gregorian, renders any deviation at its focus as a Gregorian ten times greater than before, according to the numbers given—a fact which the most elementary knowledge of geometrical optics makes clear. As a Newtonian the disturbance may be so slight in this particular instance as to detract but little from its usual slightly imperfect definition, even when, as in "E. H.'s" case, the mirror may be from the hands of a maker of the first repute.

In addition to this insurmountable source of error in "Ell Hay's" ill-advised perforation of a good mirror to make a sorry make-shift Gregorian, remains the fact that we know nothing whatever about the matching of his small speculum. The testing of this speculum by his friend, by the use of a microscope, means nothing; indeed, with men who know, *this* statement classes along with those he gave concerning his own wonderful measurements.

Had both telescopes been perfect of their kind, and one of them at least not a miserable make-shift alteration, then perhaps we might have listened to "Ell Hay's" self-important dictum.

I thank "Hippalus" for his kind and sympathetic remarks concerning our particular "section."

H.

GRINDING AND POLISHING SPECULA.

[43170.]—In reply to "Speculum" (letter 43133) and "Astor" (query 97286), I shall endeavour to forward for publication on an early date a description of the machine figured on p. 383, so that any one interested in speculum grinding may be able to construct one without difficulty.

If "Astor" can refer to volumes XXXV. and XXXVI., he will find a great deal of information on figuring and testing glass specula. The shadow test is not likely to afford much satisfaction until he has mastered its principles.

Dalbeattie. Alex. Smith.

ELECTRIC STORAGE—A SUGGESTION.

[43171.]—As you have many inventive readers who are attempting the Quixotic (to put it mildly), might I suggest that they have scope in perfecting a system of electric storage. I thought there was a practical system till lately. I was arranging to put in Linotype machine, which requires very little power, ½H.P. or so—far too little to run our large gas-engine, which is off duty except on publication days. I thought I could use the engine to store electricity, and take it off by a small motor. This, I know, is possible; but in consulting an engineer who makes a speciality of such work, he advised me not to try it, as storage was unsatisfactory. This was against his interest, and therefore reliable. Evidently a storage system which would be certain and give high percentage of duty is still wanting. In my case, had I found the storage satisfactory, I would have gone further, and installed wind-power as the prime motor—a source of power which is waste because too variable for most modern requirements.

Journalist.

FIELD ARMOUR.

[43172.]—Modern quick-firing long-range weapons have effected a change in the art of war so profound that we are only just realising by experience that a total change of method is necessary.

Primeval war was armourless. Then armour held sway in historic times down to three centuries ago on the field. After that it was discarded as next to useless against gunpowder. Besides, troops could not manœuvre rapidly in armour. That period of projectiles and weapons lasted beyond 1870. It is now closed. The war of the present has necessarily become a war of entrenchments and sieges. Magazine rifle and machine-gun have practically abolished the bayonet charge, and that in this present war we should have ever got the bayonet to work at all is amazing testimony to the courage of our infantry, always matchless as such.

But, wherever armour can be carried, either by

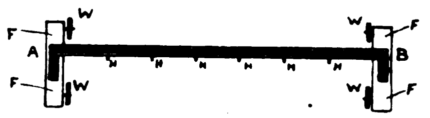

FIG. 1.—Horizontal section of iron infantry-shield. AB, iron plate, say, 4ft. high and 10ft. broad; WW, wheels; HH, iron handles; FF, framework at base.

flotation or steam traction, note that it is in full vogue. We have armoured warships and trains.

The Boer war-experiment actually up to the present has the conditions of success. The Boers are a bayonetless, entrenched, mounted infantry,

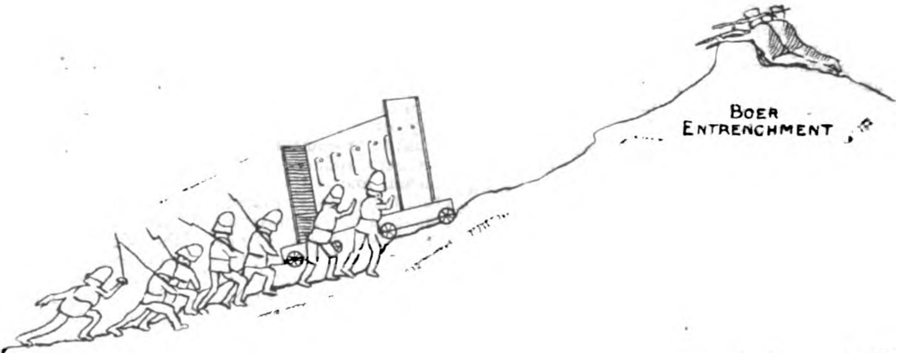

FIG. 2.—Shield being moved up by attacking force, and, if necessary, lifted bodily by them, using the handles, the wheels being locked by a pin when necessary.

only mounted in order to move rapidly to ever-fresh entrenchments.

Is the last word said, then? No.

The weak point of the Boer theory is the point we must attack. It is their system of sticking tight in entrenchments, and not manœuvring in the field at all, except for flight, and resumption of fighting elsewhere.

Armour thus can come in again. Armour, useless at Waterloo, perhaps also useless at Gravelotte—for those were battles of field tactics in the open with inferior rifles—is of the utmost use in Natal and Cape Colony to-day. It matters not if the Boers also use armour. The advantage will be thrown on the infantry who have the bayonet, and know how to use it. Intrepidity will win, not the Mauser.

Now, the following drawings show my system of

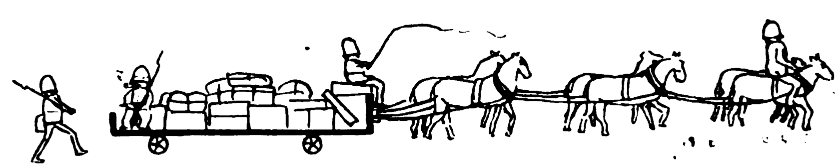

FIG. 3.—Shield adapted for transport purposes.

iron shields for infantry. The shields are useless against shells, but shells could not be used at close quarters, where the shield comes in. The whole object of the shield is merely to advance the attacking force near enough to admit of the delivery of a bayonet attack. The Boers have advantage of us at present by a mechanical device—the modern rifle—which they did not invent. Scope must once more be given for superior intrepidity to win.

My shield is a merciful device. The Boers will never stand a bayonet charge. In war it is a marvellous psychological fact that the bayonet is seldom faced. At twenty yards the moral effect is produced by the eyes of the man looking at his foe, and the inferior man, armed with bayonet or not, always gives way. The cavalry would complete the work. The shield would not, I think, be more than 4ft. high, or it would be too heavy to carry, and, of course, the ground would not permit of its being always wheeled. Hinged iron flaps might be attached at the base to protect the feet—several flaps. For river-fighting put the shields on boats. Now suppose each shield capable of covering twenty men, and of being lifted by ten of them, fifty shields would give shelter to a thousand men. This is ample to break any defence.

Dec. 23. O'Dermid W. Lawler.

WHERE IS THE IMAGE FORMED?

[43173.]—The paragraph with which Mr. Ewer commences letter 43114 (p. 406) is a rather surprising one, and I cannot at all agree with what he says there. The diagram which I gave in my letter, p. 343, is certainly a correct representation of the manner in which the image is formed, as I will now try to show. Let us trace the method by which the eye is able to see an object. In the first place, I think Mr. Ewer will admit that any object may be said to be made up of an infinite number of points, and anything that applies to one point will apply equally to all points of the object. Now, in order that the eye may see a point, it is necessary that some of the rays of light that diverge from this point in all directions be brought to a focus on the retina of the eye by means of its refractive media. It was the course of two of these rays that I traced in my diagram. We are not dealing with converging, but with diverging, rays. The fact that the rays in Mr. Ewer's diagram converge towards each other does not in any way disprove this. The principal difference between his diagram and mine is that while I only dealt with one point, he has taken a line as his object, and traces the course of one ray from each of two points, and it is impossible by means of one ray to tell how the eye will see an object. It is quite a mistake to treat the rays drawn by Mr. Ewer as if we were dealing with converging rays, because the fact is they are selected from two pencils of divergent rays, and are not brought to a focus in the eye at all. In fact, it is impossible for a normal eye to focus convergent rays: the eye would have to be more or less hypermetropic to do so.

I quite agree with Mr. Ewer that the image formed by a plane mirror is a ghost, an optical illusion, &c., and is not to be found when hunted for. But that is only what I have plainly shown before—in fact, the very word "virtual," which I used in referring to the image means that it is imaginary; but I cannot say that it is an encumbrance to the phenomenon of plane reflection—in fact, it is the phenomenon in itself. For the word means an appearance or a visible effect, and in the case of a mirror, the visible effect is the image, and hence to discard this is to dispense with the phenomenon altogether. Besides, when attempting to prove the cause or effect of anything whatever, it is the height of absurdity to disregard anything which has any connection with the question in hand.

With regard to the word "luminiferous," I think, as Mr. Ewer suggests, that the definition of light would be equally as good without this word, provided the phrase that I added be used instead. The phrase to which I refer is this: "of such frequency as to excite the sense of sight." I have not the back numbers to which he refers, and therefore cannot tell what his ideas regarding ether may be.

The well-known fact which he quotes of a beam of light passing through a box does not prove that there is no light there. It proves that while it is by means of light that we are enabled to see objects, light in itself is invisible, and the eye is only conscious of its presence when it excites the rods and cones of the retina. In order to show that light really consists of ether waves of certain frequencies, we will consider the different physical properties of ether as it vibrates at different rates. When the vibrations are comparatively slow, they manifest

themselves as heat, and the faster the vibrations the greater the heat. When they are vibrating at the rate of about 300 million million vibrations per second, we have the Hertz waves, as used in wireless telegraphy.

At 400 we have red light, and as the rate of the vibrations increases we get the different colours of the solar spectrum, violet rays vibrating the fastest, their rate being 760 million millions vibrations per second. Next we come to the X rays, with a still greater rate of vibration; but there are no nerves in the eye which are developed so as to be able to respond to these vibrations, and therefore these rays do not come under the definition of light which I gave, because they are not capable of exciting the sense of sight.

These facts lead us to one of two conclusions—either we may take it that the ether waves are themselves heat, Hertz waves, light, or X rays, according to the rate at which they are vibrating; or else we may suppose that the heat is originated by the sun, fire, &c., Hertz waves by the transmitter light by the sun, a lamp, &c., X rays by the Crookes tubes, and that each travels through the other, and sets up wave motions of certain definite frequency. In either case Mr. Ewer's statement that there is no light outside the eye is disposed of, for if his theory were correct with regard to light, similar conditions would hold good in other cases, and we should have it that there is no heat outside the body of a man or animal, no Hertz waves except at the coherer, and no X rays except on the fluorescent screen, these being the bodies which are able to receive and respond to the respective waves.

I must again state, in spite of what Mr. Ewer says, that the image formed on the retina, and which is seen in a bullock's eye, is a real inverted image formed by refraction of the rays of light from the object by the different media of the eye, and is not a reflection from the posterior surface of the lens. The reason why it is faint is because of the small number of rays which can enter, and owing to the media becoming more or less cloudy after death.

I do not think it is possible to see inside the eye by any means except the ophthalmoscope which I often use, with the possible exception of a highly hypermetropic eye, in which case it might be possible to view the retina in the manner Mr. Ewer suggests, although I do not think it would be successful on account of insufficient illumination. But what advantage would it be if he did succeed: he would merely see a red reflex of the blood-vessels of the retina, and would not see any image which might be formed there, because of the refraction of the media of the eye acting on the rays coming from such image on emerging from the eye.

C. A. Naylor, F.S.M.C.

NATURAL HISTORY STORIES.

[43174.]—THE statement in letter 43143 that the bees made their exodus, or, to put it plain, flew away, is, I should think, quite wrong. Being a bee fancier for a number of years, I think I should be able to give an opinion on the matter. The bees, on being disturbed with the axe, would soon be disturbing anything that was alive, although perhaps the majority present would attack the stores and gorge themselves with honey, but they would not fly away. Oh, no! they would stop there till their home was pulled piece by piece about them. Bees can be taken from a tree or anywhere if you can get them into a skep or straw hive, or, in fact, anything that will do for a home providing you make sure of the queen, and even then a large number forget their new home and go to where the old one was, or linger about and die.

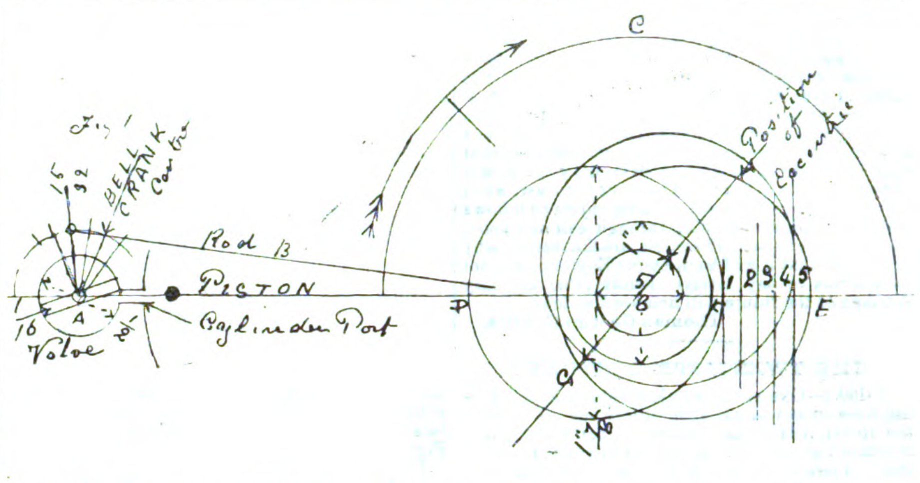
S. R., Bromsgrove.

HOW TO BUILD LIGHT ENGINE, &c.

[43175.]—THIS information looked so promising and read so nice; but are there not many more details wanting? I have tried my hardest to get at the idea complete, but give it up. Figs. 2 and 3 in illustrations are not mentioned. How does the brass triblet tube marked B come in as shown—for what purpose?

Bonchurch.

[43176.]—BEFORE going any further, I may as well give you the diagram by which to get your eccentric in right position. The flywheel and that is all cast in a piece, and if any of you should make a start you may find yourselves up in a corner when you little expect it, and you might blame "that Jack" for putting you all wrong. Fig. 1 is the valve, the port or steam way is $\frac{1}{16}$, you can make it $\frac{5}{8}$ or $\frac{3}{4}$ of an inch long, but it must be straight and linable, or it will not act properly. Diameter is $\frac{1}{2}$in. Sec. A B is the rod to bell-crank for driving same direct from the eccentric gate, below that is the piston home, and the port in valve is ready to open into the cylinder; D and E show you the range of the eccentric fore and aft, and from E to F is the stroke; G and H show you the eccentric in its proper position. Below H the stroke is marked off into five spaces. Now, when the engine is moving in the direction of the arrow it travels towards 5, opens

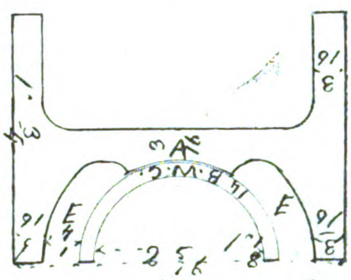


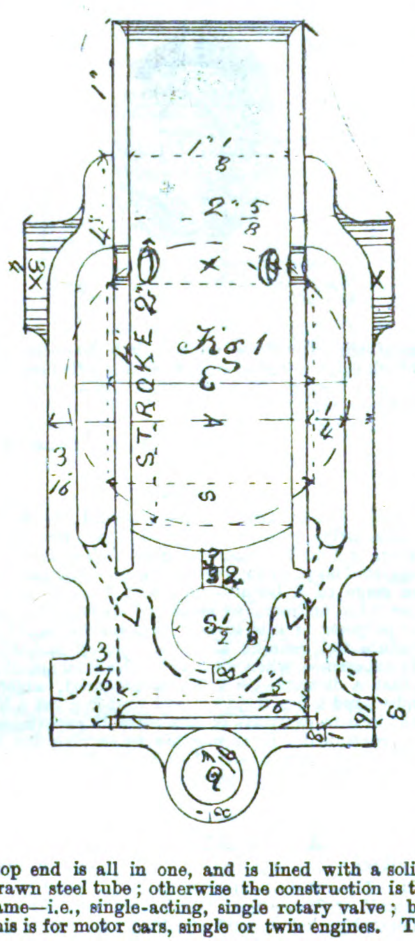
the port, until the crank comes over to the division under the arrow, when it is full open, as it travels towards C, it is closing at C, steam is cut off, all the lines and position are for the proper adjustment and putting things right, and I think plain enough to read, dimensions given so that there need not be any mistake. Of course, these are finished dimensions.

Jack of All Trades.

BUILT CYLINDER FOR LIGHT 2in. SPEED ENGINES.—II.

[43177.]—THIS cylinder differs somewhat from No. 1 (p. 428), as the jacket-valve chamber and





stop end is all in one, and is lined with a solid-drawn steel tube; otherwise the construction is the same—i.e., single-acting, single rotary valve; but this is for motor cars, single or twin engines. The jacket may be made out of any of the bronzes or ordinary cast iron or malleable cast. The dotted circle is the stroke of the engine, 2in., and it is squared off to show the action of steam—i.e., for the adjustment. S the commencement of steam, C is where it is cut off, and X is where it exhausts through the cylinder into the jacket. Now if your engine is fixed vertical, drill some holes through the bottom of the jacket (see dotted lines) into the chamber that surrounds the valve-box, and then you will need a bonnet, as shown at Q, where you can exhaust through. This bonnet can be turned round and fixed in the most convenient position for delivery to your condenser, and when your engine is in that position it will be well drained if laid upon its side, either side or inverted; then exhaust through X X either side, as the case may be. The various sketches are for a single engine; the bosses and distance pieces with the walls of the box only want repeating upon the other side opposite to carry the frame or entablature, and for studs for fixing in position, so that there will be no necessity for me to get out another drawing, as the twin engine will explain all that as laid down.

Jack of All Trades.

SPLICING.

[43178.]—THERE is no need for any carping over the proper length of a splice, because there is no proper length: it varies with the nature of the rope and also with its size. A rope is merely a collection of short fibres, so arranged and twisted as to give them coherence purely by friction. Exactly the same law applies to the splice. As a splice wastes rather more than its own length of rope, it is evident that it should be made as short as is possible, and, speaking as an old sailor, I should say that 4ft. to 5ft. is ample for any ordinary running rope of hemp. In wire ropes, it is clear that we cannot put the same twist in the rope, against which we have the greater length of each fibre. In the splice, on the other hand, we wholly lose the strength of the individual fibre, and we cannot get the surface friction, therefore the splice must be lengthened, or it will simply pull out.

Sigma.

AIRSHIP OR AEROPLANE—WHICH?

[43179.]—UNDER this heading you publish an article (p. 422) from the *Scientific American*, in which it is stated that the early flying machines in which suspension and forward motion were attempted by imitating the flapping wings of the bird were futile and wofully fatal. Now I wish to take exception to this, as, I think, very random statement, that the attempts to fly the air by the flapping-wing principle have been more fatal than those by the aëroplane, I, for one, most decidedly deny; and as to being futile, every man knows that every attempt to fly the air—either by the flapping-wing process or aëroplane, or, in fact, any other way—have one and all alike proved futile. I have no intention whatever of going into this problem any further than to suggest that the flying machine (I don't mean airship) will have to be built on the self-same principles that the bird's mechanism is designed upon; every other device that may be tried will fail, just as every device has failed up to the present time that has not for its foundation the true principles of aërial flight. I wish to point out here that an airship is a thing quite apart from a flying machine proper—these two will be as wide as the Poles asunder in their nature and work. The true flying machine will be to all intents and purposes an artificial bird, just as the locomotive is in every respect an artificial horse; whereas the airship will never be anything more than a mechanically propelled balloon. It strikes me as extremely curious that every new Yankee idea on this subject is thought a great deal of; while the man nearer home, the Englishman's ideas, are taken very little notice of. Why this should be I can-

not say; but I will suggest this much: that the chances are all in favour of bonny Britain being eventually the birthplace of the fairy carriage of the future—the flying machine. The reasons I give for this forecast is that in the first place the Briton is far more earnest in his work than your gay and brilliant-witted Yankee. He is, as a rule, more persevering in his object, whatever that may happen to be; he is less swayed by the power of the almighty dollar; and last, but not least, when his mind is once fairly set upon an object he follows it through thick and thin, through evil and good, unto the bitter end. These, Sir, are the reasons why I prophesy that it will be in bonny England, and not in America or any foreign country, that the fairy carriage of the future will first see the light.

Thomas George Challis.

THE TWENTIETH CENTURY?

[43180.]—ONE scarcely feels comfortable in differing from so logical an authority as our "Fellow of the Royal Astronomical Society," but I really find it difficult to accept his argument in your last issue, that "there never was a year 0." It strikes me that when Christ (or any other baby) was born, that this must have been in his first year, and if we wished to express his age in terms of the year, say, at three months old, we could only do this by putting it 0 year 3 months. After our Lord was one year old He entered his second year, and in the same manner, after a period of 100 years from 0, we entered the 2nd century, and so on till Monday, January 1, we entered the 20th century. We begin this century again as the 0 period, as the 00 at the end of 1900 represents the century period. Further, as regards B.C., there must have been a period of six months before our Lord was born, and this could only be expressed as 0 years 6 months B.C. The commencement of life must be a zero, and as we have B.C. and A.D., it is just the same as any other zero, as, for instance, that of a Centigrade thermometer, where 0 is the freezing-point, wherein before we register a degree we have parts of a degree, which is expressed, for instance, as + 0·6 or − 0·6, if the thermometer reads $\frac{6}{10}$ on either side of 0. **Wm. F. Stanley.**

[43181.]—UNDER this head on p. 517, Jan. 13, 1899, you did me the favour to publish a note referring to the absurdity of taking the tables in the Book of Common Prayer as an authority for the century question. They are for settling Easter, and the writer expressly explains what he means by the "next century," and inferentially why he leaves out 1900. The following note from the *Gentleman's Magazine* of April, 1800, may be of interest:—"In France, as in England, there have been disputes about the commencement of the 19th century. The astronomer Lalande thus determines the question, which, he says, was equally agitated at the end of the last century, he having in his library a pamphlet published on the subject. 'Many persons imagine that, because after having counted 17 they commence 18, the century must be changed; but this is a mistake, for when 100 years are to be counted we must pass from 99 and we arrive at 100; we have changed the 10 before we have finished the 100. Whatever calculation is to be made we commence by 1 and finish by 100; nobody has ever thought of commencing at 0 and finishing by 99.' Thus he concludes the year 1800 incontestably belongs to the 18th or old century." **Tenbyten.**

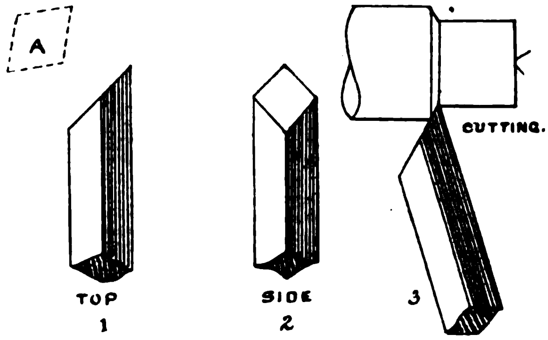
A SIMPLE HYGROMETER—THE MOON AND THE WEATHER.

[43182.]—A PIECE of ordinary twine twists and untwists with the moisture in the air. Suspend such a piece (a foot or more long) in any way—e.g., from one end of a piece of stout wire bent at a right angle and stuck in a bottle. To the lower end attach a rod, quill, or the like as a pointer (string attached to middle of pointer), and place below a piece of cardboard with graduated circle. Perhaps some of your readers may be disposed to make observations with this, and report, especially as to the indications of the instrument in regard to the barometer and rainfall.

With regard to "F.R.A.S.'s" playful criticism of the passage I translated from Augot, I cannot see that the passage is at all vague; indeed, it partakes of that lucidity which characterises the book throughout. It shows, however, that judicial quality, that philosophical suspense of judgment on a matter in course of elucidation, which is not always conspicuous in the utterances of "F.R.A.S.," and which may possibly be somewhat foreign to his temperament. The point of the passage seems to have been rather missed by your correspondent "S. R." **A. B. M.**

CUTTING EDGES FOR METAL.

[43183.]—THE late Mr. Adam Hilger, the optician, and one of the best mechanicians of our time, told me that he knew of no better edge than that obtained by grinding a four-sided prism at an angle of 45°, so as to produce a rhombic facet, as shown in the sketch at A. This tool, a graver in fact, to be held with one of its angles uppermost, and its ground facet in a nearly vertical position, as shown in Fig. 3.



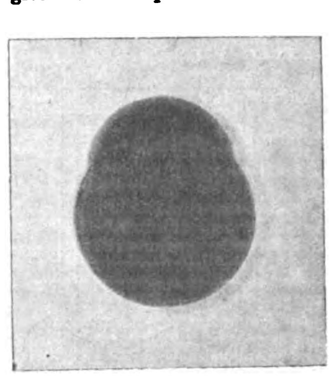
The cutting edge of this tool is about 60°, and this, Mr. Hilger told me, was equally suitable for steel and brass. He used the same style of tool for both metals, rejecting the commonly-taught opinion that an obtuser angle of cutting-edge was better for brass. I do not remember whether he approved of an almost rectangular edge for finishing brasswork, but I think not.

As a general principle, it seems that an edge for any purpose should be as acute as will stand against the material worked on without chipping, bending, or unduly heating, and it would be highly interesting if someone with the necessary appliances would experiment with edges ground at various angles, and used on different materials, so as to give us, once for all, the best information on the subject. I would suggest that the weight of metal removed, and the temperature acquired by the tool would form important criteria as to the suitability of the edge. The tool which kept itself coolest and removed the most material in a given time being awarded the palm. **Richard Inwards.**

20, Bartholomew-villas, N.W.

PENUMBRA OF X RAYS.

[43184.] — THE annexed radiograph shows a distinct penumbra produced by X rays. The radiograph represents two coins, one placed half-way over the other. In taking the radiograph the tube stood 1in. from the photographic plate. The exposure given was a quarter of an hour. On



examination it will be noticed that the outer edge of both coins is lighter than their respective centres, the coin farthest from the plate having a broader light margin. I should be glad to have an opinion from other readers as to the cause of this penumbra. **A. Stammwitz.**

OZONE.

[43185.]—SEA AIR is sometimes said to owe its health-giving power largely to the presence of ozone, and in the January *Strand Magazine* it is suggested on p. 84 to produce ozone electrically on the stage of a lecture-room and blow it gently among the audience by means of electric fans, and the proposer of this scheme believes he can "reproduce the genuine air of a country orchard." My experience, when working an electrical machine, is that a disagreeable smell is produced, which I understand is due to ozone, and that it gives a bad headache to everyone in the room if experiments are continued. Is it possible to ozonise the air without any unpleasant effect, and is it due to impurity of the ozone so produced, or to what? **Glatton.**

A LOW BAROMETER.

[43186.]—AT 8h. 23m. on the night of the 29th ult., I stood near the White Stone pond on the summit of Hampstead Heath, and read my compensated pocket aneroid 28·025in. As this reading was considerably lower than any previously taken in the same place, I thought it advisable to check the indications of the instrument by the reading of a reliable mercurial barometer.

The comparison showed the pocket instrument to be quite trustworthy. It follows from this that at the time indicated atmospheric pressure at sea level was equal to no more than 28·484in. of mercury. I think this is the lowest recorded reading about London since that of Nov. 11, 1891. Further, as the needle of the instrument had risen at least 0·05in. from the lowest point reached in the late afternoon of the 29th, owing to increase of atmospheric pressure, by the time I reached the top of the heath the barometer would seem to have indicated a lighter state of atmosphere about London that afternoon than any prevailing since Dec. 9, 1886. **William Godden.**

WENHAM'S AND "GOSSIP'S" SCIENCE.

[43187.]—APART from all reference to Biblical science, I must attack both Mr. Wenham's science, p. 429, and "Gossip's," p. 453, about the Dead Sea and its past history. These are purely mechanical and scientific subjects, and not to be ignored because Christ happened to mention them.

There are *no* "observed facts of science" to show the simultaneous fall of two large Leonids on two neighbouring cities "could never take place."

Moreover, the region of the Dead Sea has *not* had "the same geological aspect and condition" for "countless thousands of years." Mr. Wenham's science here is utterly false and worthless—"the suppositions and legends of men who knew nothing of such matters." The whole lake is now south of Jericho, but was lately (geologically speaking) wholly north of that place. The relative thicknesses of deposit, under the lake and under the Jordan, prove this recent change, and I challenge Mr. Wenham to prove it 4,000 years old. He talks again of "upheaval," but all other travellers see only a downthrow of strata, the whole valley being but a small portion of the length of a great rift, extending south across the Red Sea and Abyssinia, and even the Equator. This rift may be "countless thousands of years" old, but he has not a shadow of reason for saying the "Lake of Lot" is a year older than Lot.

That "no community could ever have resided there," is sheer imagination. Other travellers have found ruins of three or four cities near the lake. The barrenness is wholly due to the salt, which is not in the strata. The chief hill of salt, at the south-end, is called Jebel Esdoom (or Sodom Hill), and has every appearance of having fallen from the sky, like the similar hill near Biskra in Algeria. The vales of fresh-water streams that enter the lake, as at the Scriptural Engeddi, are very fertile, and abound in date palms. The high barometric pressure may make them sanatoria some day, and there may be factories of bromine for photography. When the lake was fifty miles north of its present site, its present bed must have been as described in Genesis xiii. 10, "well watered everywhere" and "like the garden of the Lord." It is perfectly ridiculous that matters of mechanical science are to be falsified with sham sciences like Wenham's and "Gossip's."

"Gossip," p. 453, quotes Josephus to prove Biblical science false, and might just as well quote Milton. Of course, the prophets taught no natural secrets (unless, perhaps, the dietary laws in Leviticus forbidding shellfish are very sanatory); but it is untrue that they touched nothing which was naturally to be discovered. No modern science was needed to show the days of creation were lengthy ages, for St. Augustine deduced this from Scripture alone. That this earth was formed before the sun is "Biblical science," and also recent science of yesterday, but not of one or ten centuries ago. That the stars are numerous enough to be ranked with grains of desert sand, is Biblical science of Abraham's time and of to-day; but not of three centuries ago, for the stars visible to the naked eye are barely 2000, and outnumbered by a thimbleful of sand. The contrast between the littleness of the earth and vastness of heavens (which the Bible always mentions before the earth) appears in no ancient book but the Bible. Elsewhere (even as

late as the Koran) we read of the earth and heavens as almost equal spaces, like the floor and ceiling of a room.

For all practical purposes the earth is fixed, and the sun goes round it. To state the contrary would merely make the teacher incredible. The millions that rejected Pythagoras would equally have rejected Moses or Isaiah for this, and all their moral teaching. Equally mischievous would be teaching the sun to be larger than the earth. In Job's time the fact of the sun and stars passing under the northern parts of earth was wondered at, as "hanging the earth upon nothing."

Instead of indulging "fancy with speculations," it would be more to the point to go and examine the alleged remains of Noah's Ark next summer. Why will not Mr. Wendham or "Gossip" attempt this? E. L. Garbett.

ORNAMENTAL TURNING.

[43188.]—In reply to "E." 43158, in our last issue, I have the pleasure to say that it is my intention to include the details of geometric chuck, as I wish to make the series complete in every way. I will prepare the same as early as possible, and hope to have the first ready to follow my next on the spiral apparatus. J. H. Evans.

USEFUL AND SCIENTIFIC NOTES.

A REMARKABLE instance of fluctuating values is to be found in the comparison of cost of steamers. It was stated recently that in 1894 a steamer cost £6 per ton deadweight, plates being about £5 5s. per ton, whereas to-day the cost is about £9 5s. per ton, £8 per ton being for plates.

THE Home Secretary has issued a notice under section 8 (1) of the Factory and Workshop Act, 1891, certifying that, in his opinion, the processes of sorting, willeying, washing, combing, and carding wool, goat-hair, and camel-hair, and processes incidental thereto are dangerous or injurious to health.

A SCHEME for extending Euston Station so as to make it front upon the square has been submitted by the London and North-Western Railway Company to the St. Pancras Vestry. The plans involve the closing of Seymour-row, Melton-mews, Euston-place, Euston-grove, and Euston-crescent, besides portions of half a dozen other thoroughfares. Provision is made for the construction of a new street and a new tunnel.

THE "ANNUAIRE ASTRONOMIQUE ET METEOROLOGIQUE" for 1900, by M. Camille Flammarion, has been issued (Paris: Librairie, Ernest Flammarion), and will be found very interesting. The frontispiece is a comparison of "La Grand Lunette de l'Exposition" with the height of the towers of Notre Dame. An illustrated description of this siderostat was given in our number for April 14, 1899. There are many notes which will be useful to amateur astronomers all over the world.

A MOTOR CARRIAGE has recently been introduced in France which is normally propelled solely by an oil-engine, but on hilly ground is helped by an electric motor. The oil-engine works at a constant speed, and when the vehicle does not absorb all the engine's power the excess drives the motor as a dynamo and charges accumulators. As the accumulators only have to supply power occasionally they are kept fully charged, and can therefore safely give rates of discharge which would seriously damage them if the cells were only partially charged. The engine is direct coupled to the dynamomotor, which is shunt-wound, and is used to start up the engine. The rate of charging can be adjusted by field regulation. Changes of speed are effected mechanically.

Coppering a Negative.—The following process, which is described by Graf Vittorio Turati, of Milan, in Liesegang's *Photographisches Almanach*, might be useful for the preparation of small ornaments by means of photography. The negative or positive should be prepared by means of the wet-collodion process, and fixed and washed as usual, only preferably on plate glass. The negative should be placed in a clean dish, and covered with the ordinary cupric bromide intensifying solution, and then blackened with silver nitrate, and this should be repeated two or three times, and after washing, the negative may be dried by heat, or spontaneously. It should now be placed in an accurately-levelled dish, and covered to the depth of about one millimètre with a saturated solution of cupric sulphate, and allowed to remain for about five minutes. Then should be added about half the quantity of fresh cupric sulphate solution which has been acidulated with sulphuric acid, and the dish well rocked. Fine iron filings should now be carefully and evenly sifted over the whole of the negative, when the negative image will be seen to gradually cover itself with a fine deposit of red copper, and it is then only necessary to rinse it under a tap and allow it to dry.

REPLIES TO QUERIES.

*** *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[96613.]—**Motor Waggon** (U.Q.)—From data given in a paper by George A. Buris, read Nov. 2 before the Civil and Mechanical Engineers' Society, it appears that on a level the power should be—

$$\frac{\text{miles per hour} \times \text{gross weight in tons}}{C}$$

C is 6·25 for effective horse-power exerted by the wheels. C is 4·165 for indicated horse-power (allowing an efficiency of transmission from pistons to road wheels $= \frac{2}{3}$). Assuming "walking pace" to be four miles, your per hour indicated horse-power of a level should be—

$$\frac{4 \times 1}{4 \cdot 165} = 0 \cdot 961 \text{ horse-power.}$$

Say 1I.H.P. GLATTON.

[96784.]—**Grate Front** (U.Q.)—With reference to my grate front, I mean that the bars in grate mentioned in my sketch must be loose, as I want them to take out. Many thanks to "Glatton." R. QUICK.

[96964.]—**Typewriter Ink Ribbons** (U.Q.)—What looks like a good recipe appears on p. 507, Vol. LXVII. If you have not got it, send 2½d. for No. 1738, which contains this page. Other recipes are given in the following places:—Vol. LXVI. pp. 232 and 439. Vol. LXVIII. p. 242 (this is by "Regent's Park," and is ridiculed, as so many of that gentleman's replies are, the following week, on p. 263), also p. 285. GLATTON.

[96965.]—**Equatorial** (U.Q.)—An air-clock is described on p. 283, Vol. XXX., which might be adapted for your purpose. A number of letters appeared in Vol. XXXII. on the subject of sand driving clocks, from which I gather that while damp or badly washed sand is useless; clean, dry sand is so good that satisfactory photographs of the moon have been taken by means of a sand clock. GLATTON.

[97063.]—**Utilising Surplus Power** (U.Q.)—Your best plan would be to refer to the makers of the engine. If you prefer to design your own gear, let me know the revs. per minute the engine runs at, when loaded, to give the full power. I presume 350 revs. is the speed at half-power. Is there an explosion at each stroke? GLATTON.

[97069.]—**Formula.**—Your query is not clear as it stands. What is meant by "mass," for instance? Does it consist of a similar compound, but in different proportions? Perhaps if you state it more clearly some of our mathematical readers may reply. GLATTON.

[97075.]—**Small Motor** (U.Q.)—I do not know the "Bee" motor; but Mr. Seal, of Castelnau, Hammersmith, advertised small hot-air engines in these columns. The "Robinson" hot-air engine is well designed also. GLATTON.

[97091.]—**Defective Circuit** (U.Q.)—Although you say connections are clean, there may sometimes be a little dust on one. A sliding contact-piece in your clock would minimise the risk of this. You would be more likely to get a useful reply if you gave a diagrammatic sketch of the connections. GLATTON.

[97099.]—**Metal Spinning.**—If I am not mistaken, it has been pointed out in these pages that there is no book about metal spinning, and, moreover, that it is an art which cannot be acquired without plenty of practical experience. There is plenty of information about metal spinning in the pages of this paper; but, as the querist probably knows, it is one of the few arts the details of which have not been published. I wonder whether he ever gave any information. Aluminium lends itself readily to all the arts of the craftsman. PAGAN.

[97119.]—**Water-Gas.**—The querist has only to take the trouble to look through your back volumes to find out all that is worth knowing about "water-gas." I believe there is a company which supplies the "most improved method of manufacturing water-gas," but as to the "number of thermal units," that is merely a question which depends for its answer on the quality of the water-gas. It would be interesting to learn whether any of the water-gas schemes are really economical, for, I think, they have all been described in the back volumes. M. T.

[97125.]—**Colouring Metals.**—Generally speaking, they are coloured by means of coloured lacquers; but some are, so to speak, self-coloured—e.g., silver, with nitric acid, when exposed to light, turns black. Treated with bichromate of potash, turns something like red. As watches are mentioned, and they mostly have silver cases, see Gee's "Silversmiths' Handbook" (think that is title), published by Lockwood and Son. TIBBY.

[97196.]—**Science and Art Department Certificates.**—In reference to this question and the replies on p. 409, it would be as well to have a little matter cleared up. In my reply on that page I say the price of the "Directory" is 6d.—"Clara" (same page) gives 1s. 6d. Surely there cannot be much doubt about what should be a matter of fact. Perhaps Messrs. Eyre and Spottiswoode will kindly say what is really the price of the "Directory." M. T.

[97210.]—**Steel-Facing Copper Plates.**—(1) The best voltage is 4–6 volts. Your dynamo at present is useless for this work; must be rewound. (2) External resistance may be dispensed with if an adjustable resistance is inserted in shunt. (3) Best solution is the sulphate-of-iron and chloride-of-ammonium solution. A little practical help would be of more value than a whole page of written instruction. Are you near London? ELECTROPLATER.

[97219.]—**Rope-Driving.**—When replying to querist week or two back, I mistook figures he gave for 28ft. centres, or should certainly not have advised using a belt at all, but a shaft connection with skew or spiral gear direct. I may here add, to attempt to drive a car by belt 2½ft. centres means for the user an unmitigated source of trouble and annoyance. MONTY.

[97245.]—**H.P. for Car.**—

$$\text{H.P.} = \frac{W\,M}{335}\left(\frac{K}{2{,}000} \pm \sin.\,\theta\right)$$

Where—

W = weight of car and passenger in pounds.

M = speed in miles per hour.

K = resistance to traction in pounds per ton on a level, and is about 25lb. per ton.

S = angle of grade (Sprague).

Rickenzaun prefers equation in this form—

$$\text{H.P.} = \frac{W\,K\,S}{33{,}000} \pm w\,(\cdot 22408)\,\frac{\sin.\,\theta}{33{,}000}$$

Where w = weight in tons, and S speed in feet per minute, core on continuous current. Dynamo and motor: generally the theoretical value to actual H.P. is about 100 to 64. To find velocity of discharge in feet per second of water flowing through sluice or penstock. Multiply square root of height from centre of orifice to surface of water by 8·025. To find height of fall necessary to give a certain velocity: Divide square of velocity in feet per second by 64·4. Number of cubic feet of water discharged through sluice per second is obtained by multiplying area of sluice opening in square feet by number of seconds, and multiplying product by five times square root of height in feet from centre of orifice to the surface of water. To find quantity of water in gallons per second discharged through sluice: Multiply area of orifice in square feet by number of seconds, and this by 31·5 square root of height in feet from centre of orifice to the surface of water. Effective fall is half head of contact added to fall. Theoretical H.P. equals quantity of water in cubic feet per minute multiplied by head of water from tail race in feet, and this by 0·001892 (Björling.) Trolley wire, size No. of B. and S. Cable wire of closed conduits, say, No. 4 hard-drawn copper. (Atkinson.) REGENT'S PARK.

[97249.]—**Vertical Boiler.**—Coat with paraffin oil, solid paraffin, and blacklead. Mixture white lead and tallow; ditto, equal parts beeswax and Ozokerit; ditto, camphor ½lb., melted lard 1lb. After clearing off scum, add q.s. of blacklead, and leave on. REGENT'S PARK.

[97256.]—**Windmills.**—Many thanks to "Glatton" for kind reply. With regard to the instrument mentioned for velocity, what exact purpose does the wire gauze and thin metal plates serve, and what governs their size. ALTERNATOR.

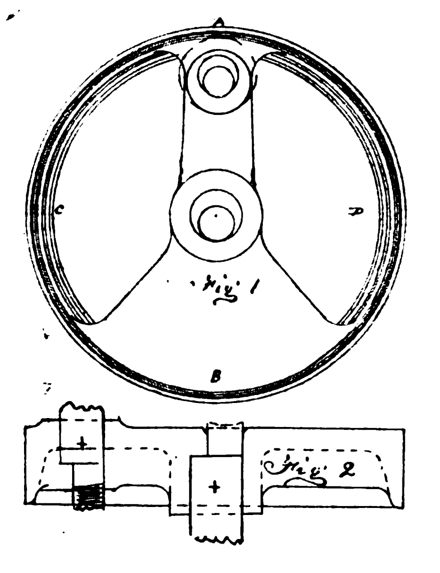
[97257.]—**Coherer.**—Many thanks to Mr. Bottone for his very kind reply, which I much appreciate. With regard to alternator, I proposed to make an armature with the stampings as supplied for Edison phono-motor, 40 teeth, 7in. diameter. The field-magnet would be a ring with a number of bolts fitted round inside to receive the wire, to be hoisted with about 10volt. 2amp., from accumulator or small dynamo; then to use a step up tranformer to raise the voltage; and so excite a Seale coil. Would this work? If so, could you say suitable size wire to use, and approximate quantity and voltage to expect. Also, must I have as many poles in field-magnets as in armature, viz., forty, or will any number do? ALTERNATOR.

[97267.]—**Indelible Washing Ink.**—1. Crystallised chloride copper 8·52 parts, chloride sodium 10·65, chloride ammonium 5·35, water 60 parts. 2. Aniline hydrochlorate 20 parts, water distilled 30 parts, mucilage acacia 20 parts, glycerine 10 parts, 4 parts of No. 2 to be mixed with 1 of No. 1; this practically a solution of nigrosin. REGENT'S PARK.

[97280.]—**Steam Pressure in Locomotives.**—The new six-coupled express engines of the N.E.R. have a working pressure of 200lb. per square inch. Other dimensions: cylinders, 20in. by 26in. (outside), leading four-wheeled bogie; diameter of wheels, 3ft. 7¼in.; six-coupled wheels, diameter, 6ft. 1¼in. Boiler: length between tube-plates, 15ft.; outside diameter, 4ft. 9in.; firebox, 8ft. long. Weight in working order: engine, 62¼ tons; tender, 38½ tons.

C. P.

[97283.]—**Motor Tricycle.**—Why should you key them on shaft at all, when the fitting of them on, as the sketch here given, will insure their fixity,



and will never sheer off or work loose, the eccentric pin being two-thirds of the diameter of the shaft? Fig. 1 gives the back view of back disc, with balance-weight all in one. The crank-pin can be put in one side and riveted, and the other a nut put on. Fig. 2, section through A B, the dotted lines show you the section the other way C D. These can be fitted much quicker than messing about with square keys and key way.

JACK OF ALL TRADES.

[97283.]—**Motor Tricycle.**—Unless you are a first-class turner, and used to working with a micrometer to ·0001″, do not attempt the parallel-shaft business. The taper hole is much easier if you go the right way about it, and stands a better chance of running truer; besides, you may, from some unforeseen cause, want them apart again. To bore wheels properly, first make a taper plug gauge, to size on which put a depth gauge line, then make a flat-ended nose chuck to fit your lathe, into which you must screw a taper plug at a distance that equals throw of crank; this plug to have end screwed to take a nut to secure flywheel when turning. Next take flywheel, chuck it in jaw chuck, and rough turn and face the one side, with crank-pin boss right depth from edge of wheel; throw out of centre, and bore crank-pin hole first, finishing with larger size outward to your plug-gauge, which it must fit accurately up to the line. Finish as many wheels as you require to this operation first, then put nose-chuck on, fix wheel on eccentric stud, and you will be able to bore centre-hole dead true and finish wheels complete, and make as many as you like with certainty that centres will be all alike. If making any number, then make sheet-metal gauges for outside diameter and inside depth from face. There is no better or simpler way of doing them.

MONTY.

[97284.] — **Geometrical Progression.** — The evident indignation of Mr. Burgess on p. 455 tempted me to turn up the original replies, which deal with a matter of some mathematical interest. The question of courtesy is nothing to do with a stranger who joins in like this, but Mr. Burgess's remarks on algebra are another matter. To begin with, it is not sound algebra to speak of a "biquadratic which happens to permit of further resolution into quadratic factors," inasmuch as any biquadratic with numerical coefficients can easily be broken up into quadratic factors with real coefficients by anyone who is able to solve a cubic. Frequently the easiest way of performing such factorisation is to guess at the required numbers, and try if the guesses will fit; but such a process does not involve any assumption, much less an "arbitrary assumption." "H. T. B." says there was no guessing in the solution he obtained, and since this was so, a querist is reasonable in asking how he did arrive at the statement $r = x$; also how such an assumption can be said to be justified by the result when part of the result is such as to negative the assumption. The solution offered by "A. O. S." is, of course, quite sound up to the point of the indeterminate equation—

$$x + 20r = 42;$$

but the only way to continue on his lines is to say: Let us see if any solutions can be found which make x and r both positive integers; of such solutions it is clear there is at most but one, namely—

$$x = 2$$
$$r = 2$$

and since this result satisfies the original conditions, we have for certain one solution of the problem. The solution by "C. P." is practically the form which would be adopted by any experienced mathematician. "Ontario's" subsequent problem is of just the same sort, and can be solved in a few lines. We have at once from the data—

$$x(1 + r + r^2 + r^3 + r^4 + r^5) = 315$$
$$x(1 + r^5) = 165$$

Elminating x, we get at once—

$$21(1 + r)(1 - r + r^2 - r^3 + r^4) = 11(1 + r^2 + r^4)(1 + r),$$

i.e., $(1 + r)(10 - 21r + 10r^2 - 21r^3 + 10r^4) = 0,$

i.e., $r^2(1 + r)\left[10\left(r + \frac{1}{r}\right)^2 - 21\left(r + \frac{1}{r}\right) - 10\right] = 0$

i.e., $r^2(1 + r)\left[5\left(r + \frac{1}{r}\right) + 2\right]\left[2\left(r + \frac{1}{r}\right) - 5\right] = 0$

i.e., $(1 + r)[5r^2 + 2r + 5][2r^2 - 5r + 2] = 0$

Of this there are two imaginary solutions corresponding to the second factor and three real ones, namely,

$$r = -1$$
$$r = 2$$
$$r = \tfrac{1}{2}$$

The finish of these has no arithmetical meaning, and the others lead to

$$r = 2 \qquad x = 5$$
$$r = \tfrac{1}{2} \qquad x = 160$$

Of course, the two series have the same terms in reverse orders. On this question, Mr. Burgess's argument is, if I may say so without discourtesy, quite worthless, for it states that r being integral, and equal to $\frac{315 - x}{150 + x}$, which is equal to $2 + \frac{15 - 3x}{150 + x}$—then r is necessarily 2. Please observe that the same argument shows that r being equal to $\frac{315 - x}{150 + x}$ which is equal to $-1 + \frac{465}{150 + x}$, must necessarily be -1! Or, better still, r being equal to the fraction $\frac{315 - x}{150 + x}$, must necessarily be zero. Furthermore, some quintics can be reduced to quadratics, *vide supra*. With all respect for the injured feelings of Mr. Burgess, I submit that the tone of his letter was not justified by the contents of the same.

QUIVIS.

[97284.] — **Geometrical Progression.** — Your method is quite correct where whole numbers are concerned; but, as you require another solution in quadratics, I will suppose a more difficult case with fractions, and I will use my method of dealing with biquadratics, described some months ago in these columns. Suppose, then, that $r = \frac{5}{3}$ and $x = \frac{4}{7}$, then it will be found that the sum of six terms of the series is $\frac{4,265}{243}$, and the sum of the first and last terms is $\frac{13,472}{1,701}$. The first is represented by $\frac{x(r^6 - 1)}{r - 1}$ and the second by $x(1 + r^5)$; eliminating x and reducing we get $931\left(\frac{r - 1}{r^6 - 1}\right) = \frac{421}{1 + r^5}$. This can be reduced to a biquadratic equation—

$$r^4 - \frac{931}{510}r^3 + r^2 - \frac{931}{510}r + 1 = 0.$$

Now bring all the terms except r^4 and r^2 to the right; then we have, solving as if for a quadratic in r^2—

$$r^4 + r^2 + \left(\frac{1}{2}\right)^2 = \frac{931}{510}r^3 + \frac{931}{510}r - \frac{3}{4}.$$

Then— $r^2 + \frac{1}{2} = \sqrt{\frac{931}{510}r^3 + \frac{931}{510}r - \frac{3}{4}}.$

This may be put in the form—

$$\frac{r}{510}\sqrt{931 \times 510\,r + \frac{931 \times 510}{r} - \frac{3 \times 510^2}{4r^2}}.$$

The last term amounts to $-\frac{195,075}{r^2}$. Now suppose we did not know the value of r, except that it is a fraction of the form $\frac{p}{q}$. It will be seen, on looking at the biquadratic above given, that, owing to the symmetry of the coefficients, if one of the roots is $\frac{p}{q}$, another must be its reciprocal $\frac{q}{p}$, as, dividing by r^4, you get the same equation, but with the r's in the denominators. Putting, therefore, $\frac{p^2}{q^2}$ or $\frac{q^2}{p^2}$ for r^2 in the last term under the radix, the square numbers which will divide the numerator exactly are 9 and 25, so that r is $\frac{5}{3}$ or $\frac{3}{5}$. Either of these values will make the terms under the radix a perfect square whole number, and the two sides of the equation will balance each other; then x can be found to be $\frac{4}{7}$, or $\frac{12,500}{1,710}$. This latter value is simply the last term of the series, so that the two values of r and x give the same series. In one case the series is to be read from left to right, and in the other from right to left. The other two roots are imaginary.

Bath. M.I.C.E.

[97284.] — **Geometrical Progression.** — It is strange that Mr. Burgess, in his reply on p. 455, has failed to notice that "Ontario's" latest problem is practically identical with the previous one (query 96725), at least as far as the method of solution is concerned. It is true that each individual equation is a quintic, but considered as simultaneous their solution involves only the treatment of a biquadratic identical with that reached in my solution to query 96725. Suppose S the sum of the six terms, and Σ the sum of the extremes. We have—

$$\frac{a(r^5 + r^4 + \ldots + 1)}{a(r^5 + 1)} = \frac{S}{\Sigma}$$

Throwing out the common factor $a(r + 1)$ this becomes—

$$\frac{r^4 + r^2 + 1}{r^4 - r^3 + r^2 - r + 1} = \frac{S}{\Sigma}$$

$$\therefore \frac{r^4 + r^2 + 1}{r^3 + r} = \frac{S}{S - \Sigma}$$

$$\therefore \frac{(r^2 + 1 + r)(r^2 + 1 - r)}{r(r + 1)} = \frac{S}{S - \Sigma}$$

which is identical with my equation on p. 189, and reduces to the quadratic $x - \frac{1}{x} = \frac{S}{S - \Sigma}$ where $x = \frac{r^2 + 1}{r}$. As in the other case, this is a general solution for all values of S and Σ. With the numbers given by Ontario $\frac{S}{S - \Sigma} = \frac{21}{10}$. This is the same numerical result as reached by the evacuation of $\frac{S^2 + \Sigma}{S^2 - \Sigma}$ on p. 189. It is, therefore, obvious that "Ontario" derives both problems from the same source. We have, as before $x = \frac{5}{2}$ or $-\frac{2}{5}$, whence $r = 2$, or $\frac{1}{2}$ or $\frac{-1 \pm 2\sqrt{-6}}{5}$. Since $a = \frac{\Sigma}{r^5 + 1}$ we have, from the real values of r, $a = 5$, or 160.

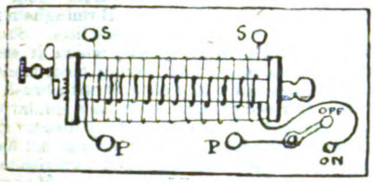
C. P.

[97284.]—**Geometrical Progression.**—The sum of the terms of this G.P. having been given together with the sum of the first and last terms, nothing more is necessary—not even the number of terms, for that is involved—in order to determine by a simple equation what the particular series is. "Ontario's" method is quite right so far as he has shown it; but he does not state his difficulty, nor has he been quite frank in explaining why the remainder is "$15 - 3x$ *or* $15 - 3x = 0$." Why *or*? There is nothing in the equation $\frac{315 - x}{150 + x}$ viewed as an ordinary equation, to suggest, necessarily, that this remainder = 0, though it is really the case. In any g.p. series $\frac{s - a}{s - l}$ = ratio (where a = first, and l = the last term) *without a remainder*, which is seen to be the case with $\frac{315 - x}{150 + x}$, for, if 5, the value of x, be substituted, we get $\frac{310}{155} = 2$. Now, as it is certain that the algebraical division cannot produce a different quotient than the arithmetical one, with the same divisor and dividend, we are invited to look for a reason why. In this case there appears to be a fraction more than 2, and it is found in the fact that a number *greater* by 5 is being divided by another *less* by 5 than the actual numbers. The result of the algebraical division being that the numerical excess is balanced by the deficiency of the x portion of the binominal $15 - 3x$. But this would not be true in any other case than this particular kind of problem, because in this case the assumed x represents two things — the actual numerical *value* of the first term, and also that it *is* the first term, since the formula $\frac{s - a}{s - l}$ indicates that the prime condition is the deduction of the *first* term, whatever be its numerical value. And this is the reason why "Ontario's" remainder $15 - 3x = 0$; it is $\frac{15 - 3x}{150 + x} = \frac{15 - 15}{150 + x} = \frac{0}{155}$. The

entire working of the question is: Let x = first term; then $165 - x$ = the last. And $\frac{s - a}{s - l} = \frac{315 - x}{315 - (165 - x)}$ = ratio. $= \frac{315 - x}{150 + x} = 2 + \frac{15 - 3x}{150 + x}$—an apparent fraction which, for the reason given, requires that the $15 - 3x$ should $= 0$, from which $x = 5$. One function of this x is to represent the actual value; its other function is to represent or symbolise the *first term*, and therefore gives both the ratio and first term in one operation. JAMES PARIS.

[97289.]—**Double Vision.**—Double vision, such as you describe, came upon me eight years ago, and got slowly worse for two years. I tried three doctors and two opticians, who could do nothing with it, though they tried many kinds of spectacles. Then I went to John Browning, optician, Strand. He said it was a very uncommon form of astigmatism, and he fitted me with spectacles that have quite cured it. I mean that I see clearly and singly with the spectacles, but without them vision is double, as it used to be, but not getting worse. W. M.

[97295.]—**Coil Connection.**—TO MR. BOTTONE.—The annexed sketch, in which the primary is indicated by heavy lines, and the secondary by finer



ones, illustrates the manner of connecting up. The battery wires are coupled to terminals, P P, and the shocking handles to S S. Presuming you are using a carbon zinc battery, you will find the following excitant give good results:—Chromic acid, 3oz.; water, 1 pint; oil of vitriol, 3 measured ounces. Mix in the order given, and do not use until quite cold. The solution can be kept in a glass bottle. Do not return the spent solution to the stock bottle; when it gets olive coloured, throw it away and replace it by fresh solution from the stock bottle. To keep the battery in good order, always plunge the zinc-carbon elements in boiling water, as far as the solution has reached, for a few seconds; then rear up to dry. S. BOTTONE.

[97296.]—**Gas Engine.**—Make the trunk piston as shown in reply 96864, page 429, Dec. 22, 1899. Make the hollow end ⅞in. deep, and allow ¼in. for clearance end of stroke, and that quarter full counter bored $\frac{1}{16}$ below the cylinder bore. Valves: air, ¾in. or ⅞in.; exhaust, ⅞in. or 1in.; gas, ⅜in. or ½in. See reply to 97283. I should never think of having a forged or bent crank for such engines; but should build them as shown, either a gas-bag or a rising gas-holder in water, as used formerly. JACK OF ALL TRADES.

[97298.]—**Cements.**—The following cement will answer both your purposes. See that the parts are quite clean. Put the very best and purest gum arabic in water, and leave overnight, when it should be of the consistency of treacle. Then add calomel (mercurous chloride or subchloride of mercury) enough to make a sticky mass. Mix well. The cement sets in a few hours, but it is wiser to leave it for a day or two. Mix only for use. ERFAHRUNG.

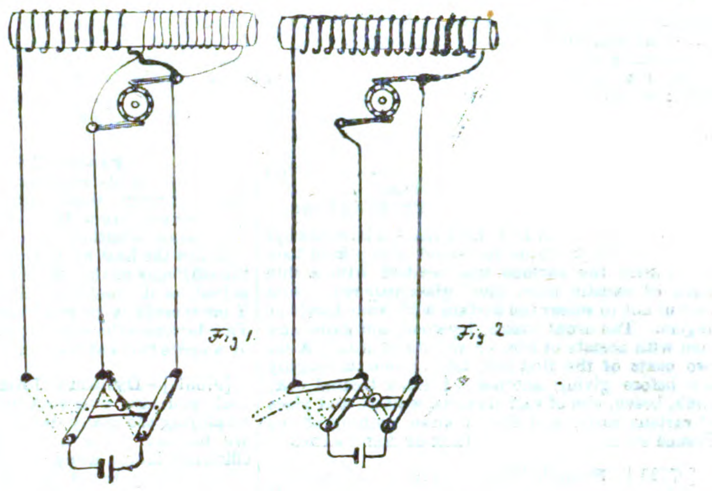
[97299.]—**Budding Roses.**—Querist asks what are Manetti stocks? Goodness knows! It depends where they are bought. The Manettia belongs to the Rubiaceæ, and in light soils seems to be a good stock for budding the Rosaceæ; but I agree with Mr. Bottone (p. 456) that it is very doubtful if they are superior to the dog-rose stock. Roses never do better than on the dog-rose of the hedgerows, and that requires a rather damp, stiff soil. The Manetti seems to be a better stock on sandy soils; but I think it soon fails. If the position is sandy, get some clay or stiff soil, and dig in about 3ft. deep. A rose-bush is always worth a little trouble. Get on own roots as soon as possible. DIJON.

[97303.]—**Soldering.**—Two of lead to one of tin, melted together in a ladle or pot. It can be bought as cheaply as you will be able to make it. Keep all other metals out, such as zinc, &c. Get some spirits of salts from your chemist, and place it in a stone jar by the fire, and throw in some scrap zinc until all action ceases—it is hastened by heat. Add as much water as there is killed spirits (chloride of zinc), and then it is ready for use. Never attempt to solder unless your copper-bit is tinned. To do so, get a lump of salammoniac, and heat your iron to a good heat (not red hot) and make a hole in the sal. with your iron. Drop a little solder in the hole, and again place in iron and it will be nicely tinned. Never get too hot; and, on the other hand, you cannot solder unless your work is the same heat as iron, or nearly so. Practice is necessary. Clean work, if dirty, by scraping. Apply solution where you want to solder. S. R. BROMSGROVE.

[97303.]—**How to Solder.**—This query is a mix, for although it is easy to solder tinplate, "brazing" copper or brass is a different thing. One thing is essential—the surfaces must be clean, and they must be made hot before the solder is applied, or that will be chilled and won't adhere. The best flux for tinplate work is chloride of zinc (spirits of salts "killed" with bits of zinc—that is, bits of zinc put in until the muriatic acid ceases to bubble). Rub the surfaces clean, apply a little of the flux, then warm up with the hot bit, and then apply the solder, melting that with the tinned copper bit, and the solder will flow where it is led. Brazing is different, and generally needs a blowpipe. The process has been described hundreds of times in back volumes, and in any of the manuals. M. T.

[97308.]—**Soda and Uric Acid.**—I asked if the soda contained in baking-powder, soda-water, and other preparations would be injurious to persons suffering from excess of uric acid in the system. "Regent's Park" replies (?) that "certain stewed fruits contain bicarbonate of soda"! He adds that "cane sugar creates acidity," and that "cream is a digestible form of fat"? Our feline pets will no doubt heartily concur with the last assertion, but its connection with my query is somewhat remote. I shall be grateful to any competent reader who can give me authentic information. "Glatton" wrote recently in praise of a lithia preparation for uric-acid troubles. Will he kindly say if he can confirm his first experience? With me it seemed to benefit the kidneys, but to increase the headaches. D. W. A.

[97309.]—**Fuller Porous Cells.**—This querist seems to have somewhat mixed up his quoted authorities. Both the first two quotations may be good advice, though opposed, because any such statements must be adapted to the particular case. Now, Mr. Perren Maycock gives the reason for his advice, and it is a sound one, as he directs the cell to be made non-porous at the part in which it is in contact with the saturated bichromate solution, which is most certainly not wanted in the neighbourhood of the zinc. The Fuller cell is used principally to give currents at high E.M.F., but only at intervals of short duration; therefore, the surface of the porous cell may be reduced, and every care taken to prevent useless diffusion of the liquids. But I cannot imagine why the quotation from my "Electricity" is brought in. The quoted section, p. 394 of third edition, does not relate to Fuller's cell, or porous cells, or even to zinc. It describes what goes on between two plates of copper in a copper solution. Its purpose is to show the effects of stratification in the liquid, and the consequent circulation, bringing a stream of acid against the upper parts of the anode. The same action occurs in the case of zincs, as described on p. 111 of my "Electricity." The querist may also find something useful about porous jars on p. 119. For the special case, soak both the top and the bottom of the cells with paraffin, for the reasons given. SIGMA.



[97310.]—**Armature.**—There are two modes by which this can be effected. Both require three lead lines from motor to switch. Fig. 1 shows the better plan; Fig. 2 the easier. In the first the motor must be compound-wound, with the series and shunt coils so arranged as to give precisely the same number of ampère turns, not coils. An ordinary Breguèt switch is arranged at the distant end, near the generator, between the three studs, so that when it is turned over to the right, as shown by the heavy lines at Fig. 1, the motor runs as a shunt motor; and when turned over to the left, as shown by the dotted lines, the motor runs as a series machine. In Fig. 2 an ordinary series-wound motor is shown. Here again a Breguèt switch is used, but in this case the left-hand arm must have a metallic extension, reaching to the extreme left-hand stud. When in the position shown in cut, the motor acts as a shunt motor; when the switch is put over to the left, as in dotted lines, as a series. And since a series and a shunt motor, *cæteris paribus*, rotate in opposite directions, your end is attained. S. BOTTONE.

[97319.]—**Belt.**—I do not see how you can expect to get a satisfactory drive with such short centre especially with ¼-twist belt. I should endeavour to put up a countershaft, and drive back again, and use certainly not less than 15ft. centres—more if possible. There is a special belt made by a Glasgow firm, with one edge overlapped on weatherboard principle for such work as you require, see advertisements in *Engineer*. I have seen leather link belting on a similar drive used when all others failed. You might try this, or a Dick's 4-ply by 9in. wide, this, I feel sure, would answer. Chain drive works well at slow speed, and is cheap. MONTY.

[97319.]—**Belt.**—Cotton manufacture: Lister, 1894 (C. Lockwood); Morris and Wilkinson, 1897 (Longmans). Wool manufacture: W. C. Bramwell's "Vade Mecum," 1881 (Thayer and Wadham, Boston), American; Jas. Burnley, "History Wool and W. Combing," 1889 (Sampson Low and Co.), &c. REGENT'S PARK.

[97319.]—**Belt.**—Has W. Moore tried the half-cross belting manufactured by C. O. Gehrckens, of Hamburg? English agents, Haughton and Co., 6, Lombard-court, London, E.C. ASHFORD HALL.

[97319.]—**Belt.**—I give approximate breaking strains of—

Leather	per square inch	3,660lb.
Best quality	,, ,, ..	6,800lb.
Stitched cotton do. solid woven....	,, ,, ..	10,420lb.
Waterproof linen.	,, ,, ..	12,000lb.

Horse-power (or 33,000ft.-lb. lifted 1ft. high): H = H.P. of pulley, P = circumferential force of power in pounds. Then H × 33,000, 1ft. high = power of pulley. Denote circumferential velocity of pulley in feet per minute by v_m; there is power in pounds—

$$P = \frac{33{,}000\ H}{v_m}\ (f\ 20).$$

Inversely, $$H = \frac{P\,v_m}{33{,}000}\ (f\ 21).$$

Rule: Query power of pulley in pounds. Divide 33,000 times the H.P. by circumferential velocity of pulley in feet per minute. To determine H.P.: Multiply power of pulley in pounds by circumferential velocity in feet per minute, and divide product by 33,000. If v = circumferential velocity of pulley in feet per second, there results $v_m = 60_v$, and (f 20) becomes, by substitution—

$$P = \frac{33{,}000\ H}{60\,v}$$

or— $$P = \frac{550\ H}{v}\ (f\ 22).$$

Inversely— $$H = \frac{P_v}{550}\ (f\ 23),\ \&c.$$

REGENT'S PARK.

[97320.]—**French Black Stain.**—Boil ½lb. chip logwood in two quarts of water. Add 1oz. pearlash, apply hot. Take ½lb. of logwood, boil as before in two quarts of water, add ½oz. verdigris, and ½oz. copperas. Strain off, put in ½lb. rusty iron filings, and apply as before. Take 1lb. of logwood, boil in four quarts of water; add double handful of

walnut peelings, boil up again, take out chip, add half-pint best vinegar, apply boiling hot. To improve it if when dry a solution of green copperas in water, 1oz. to quart, applied hot. Ebonised black stain: strong vinegar, 1gal.; extract logwood 2lb., green copperas ½lb., china blue ¼oz., nutgall 2oz. Boil over slow fire till dissolved. When cool is ready to use. Add half-pint of iron rust, obtained by steeping iron filings in strong vinegar. If you have not tried either, you have a choice.

REGENT'S PARK.

[97320.]—**French Black Stain.**—I have always found that black stains for wood of any kind took better after the surface was washed with a thin wash of caustic lime, then glass-papered, being careful not to smear the surface with your hands or fingers. The usual stains, logwood, nut galls, and then with acetate of iron or nitrate of iron. After two coats of the first hot, letting one thoroughly dry before giving another. I have treated oak, birch, beech, elm of various sorts, walnut, and pines of various sorts, and firs. I know nothing of the French stains. JACK OF ALL TRADES.

[97320.]—**French Black Stain.**—I am not sure that I can even guess what this query means. It may be some special stain, but it cannot well be French. Does the querist mean the ordinary black stain produced by solutions of logwood and sulphate of iron, or what does he mean? He must know, if, as he says, he has tried "numerous experiments from books." As a rule a solution of sulphate of iron will make oak as black as night, and, in the case of birch, a previous soaking with logwood decoction is necessary. Put the piece of wood into a boiling decoction of logwood for a quarter of an hour, and then into one of sulphate of iron.

M. T.

[97322.]—**Cement for Rubber.**—Some of these may work. Waterproof cement: Powdered resin 1, strong ammonia 10. Shellac 4, borax 1; boil in little water, and concentrate by heat to paste. Guttapercha 1lb., indiarubber 4oz.; dissolve in bisulphide of carbon. Pitch 2oz., shellac 2oz., boiled-oil 2oz.; melted together.

REGENT'S PARK.

[97322.]—**Cement for Rubber.**—A solution of caoutchouc in mineral naphtha or in bisulphide of carbon (the cheapest solvents) will cement (or unite) rubber; but I suppose this tricycle tire is vulcanised rubber, and is therefore different to caoutchouc. So far as I know there is no really successful cement. Rubber (caoutchouc) once vulcanised is practically done for: it cannot be mended, and is only of use for working up in fresh mixtures to make inferior articles. The querist, for his special purpose, might, however, try bandages of calico soaked in rubber solution. S. R.

[97323.]—**Dynamo.**—If the dynamo is constructed exactly as you state, and it is properly magnetised, so as to have a N. pole one side and a S. pole on the other, there can be but three causes for it not working: (1) The F.M. wires are coupled up to the wrong brushes, or, what amounts to the same thing, you are driving the wrong way. (2) Either the commutator sections or else the brushes short-circuit to one another. (3) The wire on the armature is not continuous, or may even have got detached from the commutator section. See any late edition of my work, "The Dynamo: How Made and How Used," for full instructions in the way of locating and remedying these parts under the heading of "Failures in Dynamos." S. BOTTONE.

[97325.]—**Wireless Telephone.**—To MR BOTTONE.—I have had no practical experience with the above, so I prefer to abide by Montaigne's dictum and write nothing. What little I know about the subject will be found in my last book "Hertzian Waves," now in the publisher's hands.

S. BOTTONE.

[97326.]—**Bell-Ringing Electrically.**—To MR. BOTTONE.—The three sets of bells must be arranged in parallel: otherwise they will not work satisfactorily. S. BOTTONE.

[97330.]—**Steel-Facing Copper Plates.**—In further reply to "Trinacria," the subjoined may be of service. (1) The best voltage for iron depositing is six volts. Since no addition to the resistance in circuit can lessen the E.M.F. of your 50-volt dynamo, you must procure one of suitable voltage. (2) Having decided upon the largest surface you are likely to require in your vat at one time, secure a dynamo of sufficient output to allow a current of 10 ampères for each square foot of surface to be coated. The anode surface should always be larger than the surface to be coated, and by varying the distance between the former and the latter in the vat, the current can be regulated to a nicety. An ammeter should always be placed in circuit so as to be able to measure exactly the current passing. (3) The best solution is made as follows: Dissolve clean iron wire in hydrochloric acid, adding iron wire until the acid will take up no more. Let this be done as rapidly as possible to avoid oxidation, and giving a boil up towards the end of the operation. For every 58 parts of iron wire dissolved, add 54 parts of salammoniac, 1 part of glycerine, and 500 parts of water. The solution must be kept as much as possible away from the air when not in use, as it oxidises so rapidly. It can, however, be renovated by the addition of more acid, more iron wire, boiling up again, and adding salammoniac.

S. BOTTONE.

[97331.]—**Dynamo Coils.**—There is too little wire on the field-magnets, hence too much current passes through these coils. This heats the wire, and detracts from the efficiency of the machine. The mere addition of outside resistance would diminish the heat by cutting down the current; but the efficiency of the dynamo would be greatly impaired, as it would not magnetise up sufficiently. Your remedy is to wind more wire on the F.M.'s. This decreases the current, but increases the number of ampère turns at the same rate. S. BOTTONE.

[97331.]—**Dynamo Coils.**—The heating shows that you are overworking your dynamo, and employing too many lamps. Four 60-watt lamps are too many for a 200-watt machine. High-efficiency lamps using less power should be substituted; they do not, however, last so long.

H. L.

[97332.]—**Electric Ignition Coil for Motor-Car.**—To MR. ALLSOP OR MR. BOTTONE.—Premising that I do not greatly prize dry cells for this purpose, I give the following specification for a coil to be used specially in conjunction with dry cells in series:—Core, a bundle of No. 22 soft iron wire, carefully annealed, 7in. long 1in. dia. Primary ½lb. No. 24 silk-covered wire, to be wound in four layers, over about 6in. of the core, the other inch being taken up by the coil heads, &c. There will be about 180 turns in each layer. The secondary should consist of ¼lb. No. 36 silk-covered copper wire. This must, of course, be separated from the primary by a stout ebonite tube, screwed into the heads of the coil. It is not necessary to build so small a coil in sections; but the greatest care must be taken to insulate perfectly. The condenser should be built up of 50 sheets of tinfoil 5in. by 4in. interleaved with paraffined paper. S. BOTTONE.

[97333.]—**Spring Pressure.**—You will get nothing in the shape of a spring—spiral, flat, or elliptic—or any other form with a working constant of 40lb. As the work advances or recedes, the power will be augmented or reduced. A spiral spring made of No. 14B.W.G. steel wire wound upon a ⅜in. mandrel, hardened and tempered, will, I think, give you 40lb.; or No. 15 would be better. Ah! I see I have made a mistake, 40lb. per square inch, then a spring of 18 or 20 gauge will give you what you want, which will be about 10lb., which is rather more than will be required for an area of ⅜in. = ·1104. JACK OF ALL TRADES.

[97333.]—**Spring Pressure.**—Find load by multiplying area of safety-valve in square inches by pressure of steam in pounds per square inch; then multiply load by diameter of coil from centre to centre of steel; divide quotient by constant 3 for round, or 4·29 for square steel, and cube root of quotient gives size of steel in sixteenths of inch when diameter is round, and side of square when square. Internal diameter should equal four times thickness of steel. Lift for all sizes taken at one-tenth of an inch. The compression or extension of spring to produce initial load should be forty times lift of valve, or 4in. for all sizes of valves with above limit. To find compression or extension of one coil in inches: cube diameter in inches of coil (centre to centre of steel), multiply by load in pounds; divide product by product of fourth power of diameter (or side of square) of steel in sixteenths of an inch, multiplied by constant of 22 for round, and 30 for square steel. REGENT'S PARK.

[97333.]—**Spring Pressure.**—The area of a ⅜in. circle being ·1104, the downward thrust must be $40 \times \cdot1104 = 4\cdot416$, or, say 4½lb. GLATTON.

[97334.]—**Spiral Barrel.**—The same principles are adopted in loam, as in the loam pattern illustrated, but the rig-up is necessarily different. The templet screw is laid in the bottom of the mould, and the striking boards are guided by it. To explain the work in detail would require many illustrations; but I will keep the request in mind. J. H.

[97335.]—**Dandruff.**—Borax 2 drachms, dissolved in camphor water 1 pint. Head washed with this lotion once or twice a week. Or wash head with tepid water, agitated with a piece of quillai bark until strong lather is produced; or with water with salt of tartar, 2 drachms of salt to 1 pint of tepid water. Discountenance, as a rule, soap. Called Pityriasis. REGENT'S PARK.

[97336.]—**Roller Bearings.**—These would be expensive luxuries on carts, cabs, &c. The loads and shocks on locomotive axles is so great that the roller bearing would probably get out of order quickly. J. H.

[97338.]—**Motor Tricycle.**—You can obtain a two-speed gear that will fit any 1¼ Dion motor tricycle, and will fulfil your requirements, the reduction being about one-half. It is similar to one I designed in August last that I mentioned before in this paper, though carried out in rather a cruder manner. It is of French vintage, and as it is already offered for sale here, I will now describe it. It is of the Crypto form, or the old sun-and-planet, and is not a new idea by any means, and cannot be claimed as a patent. It consists of a box, about 8in. diam. by 1½in. thick, formed in two halves, one of which carries an external cone, the other internal leather-faced friction cone that fits it. The spindle takes the place of the ordinary one that carries driving pinion; being made Dion taper to fit flywheels over this spindle, a sleeve is fitted, which the new pinion is placed on. This sleeve is fastened to one half the gear-box, and carries inside the box teeth round it, that engage with two small pinions, which latter gear into a large internal toothed ring, fitted inside one half the box, allowing sleeve pinion to revolve at a reduced speed at a ratio proportional to differences in the diameters. On extreme end of spindle is a bearing with a bracket that will fit axle of tricycle to hold the lot steady. Ordinarily all the box runs round; but when gear is thrown in, a light spring steel band clips one half the drum, or box, bringing low gear into play without the least shock or noise. The motor can be started with a small handle independently of pedals, and so be warmed up, without grinding up and down street for a shot in the orthodox manner. It costs, I believe, £13 complete, fixed to any machine. You can get particulars from the Automobile Supply Company, Birmingham; I have not seen it in any other firm's lists. Should clutch get covered with grease, which it seems likely to do, no arrangement having been made to throw it off, you can easily clean it with brush full of petrol. A friend of mine, who has a similar one, says he would not ride at all in a hilly district if his tricycle was not so fitted, though he has not had it long enough to give an extended experience on faults that may develop. MONTY.

[97339.]—**Accumulator.**—To MR. BOTTONE.—Place a 50-volt 16c.p. lamp in series with one wire leading from dynamo to accumulator. This will give you just the right resistance to enable you to charge the accumulator from the said dynamo, without injury. S. BOTTONE.

[97340.]—**Oil-Engines.**—In running oil-engines, a good deal depends if the compression is perfect; as to the consumption of oil used, a good oil-engine, if the compression is good, will consume between one pint and one pint and a half of paraffin per horse-power hour, costing about 6d. or 7d. per gallon. Oil-engines have been run satisfactorily using "Russolene" oil, having a density of 0·823, costing 3¾d. per gallon; a "Crossley" engine having developed 7·01B.H.P. when consuming 0·82lb. of "Russolene" per hour, a small engine would use about ½d. or ¾d. worth of oil per horse-power per hour. Oil-engines are started by getting the tube and vaporiser heated, when the engine should start by turning the flywheel a few times. A 1in. leather belt is plenty strong enough to transmit all the power developed by your engine. If the tube is heated too high, the mixture explodes too soon, causing a bump or knock in cylinder. The mixture of oil and air is, roughly speaking, one to seven. IGNITION TUBE.

[97341.]—**Small Dynamo.**—To MR. BOTTONE.—I am very doubtful whether you would possibly get as much as 4 ampères at 20 volts pressure out of a drum armature as small as 3in. long by 1½in. dia., unless, indeed, the field magnets and pole-pieces were exceptionally massive. However, if you like to try, the following are the proportions to be observed:—Armature to be wound with ½lb. No. 24 silk-covered copper wire, field magnets with 2lb. of wire of same gauge, which may, however, be cotton-covered. Fields to be connected up in shunt with brushes. For details as to the exact manner of tackling the winding and connecting up of a drum armature, I must refer you to my book "The Dynamo: How Made," wherein, at p. 86, you will find full instructions, with working drawings.

S. BOTTONE.

A TYPE of compound express locomotive in use on the Chemins de Fer du Nord, of France, has high-pressure cylinders 1ft. 1⅜in., and low-pressure cylinders 1ft. 8¾in. diameter, by 2ft. 1⅛in. stroke. The initial steam pressure is 213·3lb. per square inch; the diameter of driving-wheels, 7ft.; the grate area, 24¾sq.ft.; and the heating surface, 1,890sq.ft.

THE Russian Ministry of Ways of Communication has approved of the following projects for developing the railway system of the empire:—The construction of the projected railway from St. Petersburg to Vitebsk, on the Western Dwina, and 380 miles south of the capital; between St. Petersburg, Vologda, and Viatka in north-east Russia; and finally, the projects for bringing the port of Archangel into connection with the railway system of Russia, and for affording communication between the towns of Cheliabinsk, Orenburg, and Zarizin and the Ural Region, Siberia, and Black Sea.

UNANSWERED QUERIES.

The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered, are repeated four weeks afterwards. We trust our readers will lo k over the list, and send what information they can for the benefit of their fellow contributors.

Since our last "Glatton" has replied to 96613, 96964, 96965, 97063, 97075, 97091.

QUERIES.

[97342.]—**Incubator Tank.**—Can any reader inform me whether, if I paint the under-side of the hot-water tank in a Hearson incubator with lampblack, it will permit more heat to pass into the egg-chamber?—A. DICKESON.

[97343.]—**Influence Machine.**—I have a frictional machine with two 18in. plates, which I should like to convert into an influence machine. Will some reader please give most efficient arrangement for same, and say probable spark obtainable?—MILLS.

[97344.]—**"A Perfect Marking-Ink."**—Is the ink described under this heading on p. 38, Vol. XXX., still procurable, and what is its trade name? I believe Mr. Albert Smith, its inventor, is no longer among us.—GLATTON.

[97345.]—**Wax Phonograph Records.**—Will any reader familiar with the subject please describe fully the manufacture of wax phonograph records? I have seen one or two inquiries on the subject in the "E. M.," but no satisfactory replies were ever given. What is the composition? What is the kind of wax used in the composition of the records? Are any other ingredients used? What is the melting-point? How are the cylinders moulded—under pressure or at rest? What kind of mould is used—separable or otherwise? hot or cold? What chemical will quickly dissolve the material in a record? Is there not some process similar to hard-soap making that would answer in the manufacture of records? Would not paraffin-wax do if hardened with another higher-melting-point wax? Will acetone dissolve the material of phonograph records, and would it be possible to mould them from saturated chemical solutions? Please describe fully.—JUNIUS.

[97346.]—**Emery Wheels.**—Will any kind reader inform me how to make reliable emery wheels from emery powder? Also, where do the blocks come from, and how are they pounded into powder?—EMERY WHEELS.

[97347.]—**Air Cylinders.**—Will any kind reader tell me what thickness of steel plate I should require to make six cylinders, 4ft. long 12in. diam., to contain compressed air sufficient to supply a man inclosed in an air-tight space of 125c.ft. for five hours? At what pressure would the air be required in the cylinders when charged?—W. MURDOCH.

[97348.]—**Orientation.**—What notable examples are there of buildings possessing some specially designed orientation with respect to cardinal positions of the sun or other heavenly body? Say, with an opening allowing the sun to illuminate a particular spot on a particular day in the year, or the like.—JOHN BACON.

[97349.]—**Sore Throat and Tongue.**—Can any of our homœopathic or allopathic readers tell me the proper remedy for the following condition? I have been, and am still, painfully tormented by very tender and painful pimples at the back part and sides of tongue, and extending down and (it seems to me) all round the top of the throat, causing a painful sensation when swallowing. There is also inflammation of all the surrounding surfaces on looking into mouth. I have been taking doses of Gels., Phyto., and Bry., but with little or no results. Would any of our readers tell me the cause of this condition of mouth and throat, with the proper remedies for same? I am a non-smoker, temperate in all things, but my last attack (the seventh) of influenza (with one of those blood-red throats) left it very tender. I am sixty-four years of age, and otherwise perfectly healthy. If I go to sleep for only five minutes my tongue and mouth go quite dry, and it is some few minutes before I can get the sensation of moisture back again into mouth. Please to advise.—COMUS.

[97350.]—**Thermo Dynamics.**—What is the difference between entropy and thermal capacity (that is, sp. heat) in thermo-dynamics?—CARNOT.

[97351.]—**Coating Cardboard Cylinders.**—I wish to construct an apparatus for covering cardboard cylinders with a thin coating of wax. Will some reader kindly give me some hints how to do it?—C. C.

[97352.]—**Longitude.**—Will some reader kindly explain the simplest and nearest way to get longitude far from civilisation, and with a 6in. transit theodolite, without having Greenwich time? I hear there is a new and easy way, which was shown in some back number. Writer is in lat. South.—ARGENTINE.

[97353.]—**Altitude.**—Will some reader kindly explain the following? In taking verticals, face right and left, I use the same vernier, and carefully level the horizontal plates with telescope bubble, taking mean of readings. If the horizontal plates are not exactly level, I suppose the mean of readings to be incorrect also. Am I right in this? Can an accurate altitude be taken by adjusting telescope as a level for bubble and collimation, and then, after setting vernier of vertical arc to zero, levelling-up telescope with the levelling screws under horizontal plates, and then taking a single altitude?—ARGENTINE.

[97354.]—**Naval Coppersmiths.**—Kindly inform me what the test work is for a coppersmith in the engine-room staff of H.M. Navy, and oblige.—A. R. GEORGE.

[97355.]—**Mercury Interrupter.**—How is the platinum which fills up the hole in the bottom of the glass containing the mercury attached to the glass?—A. T.

[97356.]—**Sun's Altitude and Azimuth.**—Will some mathematical correspondent kindly explain the method of calculating the above quantities, latitude, declination, and time being known? I asked this question not long ago, and though "F.R.A.S." kindly gave me a reference to back numbers, it was useless to me, not having access to them.—FLEUR-DE-LYS.

[97357.]—**Linoleum Paste or Cement.**—Can any reader supply me with a recipe for a paste or cement for sticking linoleum, &c., to floors, wood or stone (wood mostly)? It should not be expensive to make, and should also keep well.—LINO-LAYER.

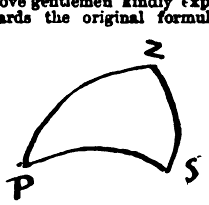
[97358.]—**Spherical Triangle.** To "ARCTURUS" or "F.R.A.S."—In working out longitude observations, I use the formula—

$$\cos. \tfrac{1}{2} P = \sqrt{\frac{\sin. \tfrac{1}{2}\Sigma \times \sin. (\tfrac{1}{2}\Sigma - SZ)}{\sin. PZ \times \sin. PS}}$$

where P = hour-angle, and $\tfrac{1}{2}\Sigma = \tfrac{1}{2}$ sum of three sides of the triangle. As used, the above formula becomes—

$$2 \log. \cos. \tfrac{1}{2} P = \log. \sin. \tfrac{1}{2}\Sigma + \log. \sin. (\tfrac{1}{2}\Sigma - SZ) + \log. \mathrm{cosec.}\ PZ + \log. \mathrm{cosec.}\ PS - 20.$$

I quite understand the development of the working form from the original, except the reason of rejecting index 20 from the sum of logs. on the right of the equation. Will either of the above gentlemen kindly explain why this is done? As regards the original formula, if it is not



asking too much from the patience of the good-natured mathematicians who so kindly help beginners, might I ask for demonstration of the formula, particularly the function of the quantity $\tfrac{1}{2}\Sigma$, which comes into so many solutions of spherical triangles? I feel that the above is of general interest to many readers of the "E.M.," and as I have not access to back numbers, please do not merely refer to them.—FLEUR-DE-LYS.

[97359.]—**Flash Powder.**—I take formula below from a recently-published annual. Is it reasonably safe to use? Picric acid, 37.5 parts; chlorate of potash, 50 parts; magnesium powder, 12.5 parts.—OPTICAL L.

[97360.]—**Wehnelt Brake.**—I have made one of these interrupters as follows. Cathode a lead plate 3in. by 4in. Anode No. 16 B.W.G. platinum fused into the end of small glass tube, and bent at right angles to face or point towards the cathode. When connected to coil, which will spark 10in. by mercury break, I could not get more than a 3in. discharge; but it was a continuous blaze, and appeared about ¼in. thick. (I should say the platinum point is about 1½ from cathode, and the dilute acid, say, 1 acid to 25 water.) I expected to get a much longer spark. Can anyone say where the fault may be? I tried at 50, 60, 70, and 100 volts. When I connected to X-ray tube the platinum plate became white hot. Does this harm the tube? Of course it was only connected for about two seconds. If left longer, am afraid it would melt the reflector. Where am I wrong?—WEHNELT.

[97361.]—**Clock-weight.**—Can some correspondent kindly tell me what is the law governing the weight of a clock-weight? I recently purchased a movement with seconds pendulum and dead-beat escapement. Since then I have seen a clock by Cooke and Sons in the possession of a neighbour, and noticed at once, not only that the weight was distinctly smaller than in mine, but that in the course of the week it falls only to about 3in. below the bottom of the pendulum, the cord passing over two pullies, whereas in my clock the weight is larger, the cord passing only round one pulley, and the weight descending 6in. every 24 hours. Why is there this difference in two similar clocks?—C. D.

[97362.]—**Perpetual Calendar.**—I see that a perpetual-motion calendar has been invented which "indicates automatically" the day of the week, the date, and the month, and shows "the 29th of February every four years." Can any reader tell me where this calendar can be seen?—A. F.

[97363.]—**Artificial Oysters.**—It is said that artificial oysters are served at the restaurants in Paris. Can any of your readers tell me how they are made? It is stated that "connoisseurs" cannot tell the difference—hence this query.—S. S.

[97364.]—**Hand-Camera Shutter.**—Will Mr. Bennett, or any other reader, kindly give full instructions how to make a shutter for ½-plate hand-camera capable of giving instantaneous exposures ranging from, say, $^1/_{50}$sec. to $^1/_5$sec., and also time exposures?—CAMERA.

[97365.]—**Deafness.**—Will "M. B., Galway," or other reader, kindly give me the best treatment for catarrhal deafness of middle ear, with nerve weakness? Patient male, age 35 years. Deafness is chronic; no discharge. Is the Drouet treatment of deafness worthy of trial? They have a branch in London. Is the above form of deafness curable?—CAMERA.

[97366.]—**Mouldy Growth on Prints.**—Last August I mounted some silver prints in optical contact with glass. They were floated on with a weak solution of gelatine, to which a few drops of thymol solution had been added. The superfluous gelatine was squeegeed off. After a month or so bright pink spots began to appear on the prints, which gradually spread into more or less circular smudges. The paper under the spots was found to be rotted, or, at any rate, to leave the glass easily when rubbed. A few weeks later similar spots were found to be forming on some platinum prints which had been mounted with the same solution on a sheet of glass, close by the first. The spots spread from a centre, gradually increasing in size, were of a bright pink colour, and appeared to be on the surface, and to be covered with small dark specks; but the paper under them seemed quite rotten, and, indeed, the spots could hardly be distinguished from those on the silver prints. Can anyone explain them? They give the impression of fungoid growths. There is no question about the complete fixation, &c., of the prints.—No. 7.

[97367.]—**Maximum Rainfall.**—I have some information as to this in London and neighbourhood; but the shortest space of time for which the maximum is recorded is one hour, but it is quite certain at the very heaviest falls never last so long. Will some observers kindly tell me the maximum for a shorter space of time, say a quarter or one-third of an hour, in London and neighbourhood, with dates?—PLUVIUS.

[97368.]—**Reconstructing Organ.**—I shall be greatly obliged if organ experts will kindly give their views on the following? We have an old organ, two manuals and full compass of pedals, eight stops on Great, eleven on Swell, two on pedals; case in good condition, and pipes for the most part decidedly good. The action, however, is antiquated and bad, and the Swell has the grave fault of ending at 4ft. C. What I want to know is whether the following plan of renovating the organ would be advisable? To replace the entire action with one of modern design, with three manuals; fit new wind-chests, &c.; leave room on each manual for a few additional stops to be added; fill up most of Swell stops down to 8ft., and form a small Choir by taking Twelfth from Great to form Open Diap., and filling it up in the Bass; two soft stops from Swell, and a new Clarionet. The new action would have all the usual couplers, including Swell Superoctave. There is not likely to be very much money available, and this plan is suggested as the cheapest, the present action being entirely past repair. Will someone give a rough estimate of cost of new action as above, new pipes to complete Swell, and new Clarionet for Choir? Would £120 cover it?—No. 7.

[97369.]—**Matches without Phosphorus.**—Can any reader tell me what results have followed the offer of a prize for matches without phosphorus that would strike anywhere, and what of those patented devices which were supposed to solve the difficulty? The prize was offered by the Belgian Government, I believe. There were many notes on the subject last year, and notes can be found on pp. 137, 168, 319, 351, 581, Vol. LXVIII. The paragraph on p. 581 seems to give some definite information; but I want to know whether anything more has been heard of those "safety matches."—PHOS. J.

[97370.]—**Balloon Fabric.**—Is there any particular method of seaming when joining? How must the silk be treated so as to become impervious to water—as a gas-bag when immersed in water, say, to a depth of 5ft.?—JOSEPH H. ROWNEY.

[97371.]—**Prevention of Silver Oxidising.**—I have a pair of candelabra which tarnish in a very short time; they are Sheffield plated silver. Presume it is due to sulphur from gas. How can I treat them so as to retain their bright silvery appearance?—CASENHEM.

[97372.]—**Aluminium.**—Be kind enough to tell me the best and easiest way to buff aluminium? Also the best and easiest way to frost the same a deep frost?—W. H. FRY.

[97373.]—**Theatre.**—Please give small sketch showing R. and L. of stage, prompt side, O.P., proscenium, wings, &c.—S. O.

[97374.]—**Windmills.**—Several inquiries, including one of my own of months ago, have done very little in getting what is evidently wanted by several—sufficient information as to size of parts and drawing of details of revolving head, carrying the wind vanes and "rudder," to enable us to construct one, say equal to ½ or 1H.P. It is useless to say "the mill is thrown out of action when wind is too strong by an arrangement of weights." That is just one of the wrinkles wanted to be described in detail. Will not some competent reader, of whom there are plenty, kindly take the trouble? The mill I am thinking of is of the circular kind, with fixed wind vanes. The vanes, I imagine, could be made of thin wood, all attached at the proper angle to circular supports; but the size of all the parts is a puzzle, and how automatically thrown out of action.—BONCHURCH.

[97375.]—**Induction Coil.**—What sized condenser should be used with an induction coil having a core 6in. long by ⅝in. diameter, wound with three layers of No. 24 silk-covered wire? Would a condenser composed of 20 sheets 4in. by 2in. give different results from one of 40 sheets 2in. by 2in.? In winding on the secondary of a ⅝in. coil, is it absolutely necessary to recover the wire with silk in places where it may have been removed for the purpose of soldering a joint? Would it not be sufficient to fold a piece of thin paper around it? What battery power (in ampères) would such a core as the above require to produce a ⅝ spark in a secondary of 6oz. of No. 40 wire? Is there any form of Leclanché cell that would suit for short experiments? I cannot find any information on these points in any book, or would not trouble your correspondents, as they must no doubt be tired of answering so many queries on the subject of coils.—D. E.

[97376.]—**Wheatstone Bridge.**—Will Mr. Bottone or Mr. Allsop give me the length and gauge of silk-covered wire (copper or German) to be used to give accurately 1 ohm resistance? I should like as short lengths as possible, to prevent the taking up of great space.—ALBERT A. HARLEY.

[97377.]—**Oil-Engine.**—Will some reader enlighten me on the following? I want to turn a gas-engine into an oil-engine. How could I do this? Please explain how to make an oil-burner to heat ignition-tube, the oil to be taken from the supply-pipe of engine? A sketch will greatly oblige.—A. C.

ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries, put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

*** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such iinformation, and we trust our readers will avail themselves of it.

The following are the initials, &c., of letters to hand up to Wednesday evening, Jan. 3, and unacknowledged elsewhere:—

THOMAS JOHSON.—W. E. Gibson.—Bonney.—Apex.—A Fellow of the Royal Astronomical Society.—H. L.—N. M. Munro.—S. R. Bottone.—John W. Faulkner.—Ignoramus.—New Moon.—Motor Car.—Jack of All Trades.

SPOKE.—You cannot place the matter in the "hands of the police," because it is not a case of fraud. part of the goods having been delivered. You are entitled to sue him for the price of the wheels not delivered, and for any loss you have sustained by their non-delivery. You should write, giving him notice that you will do this if the wheels are not delivered within a week. We do not remember that he has advertised in these pages, so that we have no ground of interference.

WM. SCOTT.—The ·60 is a very obvious misprint for ·80, and is corrected elsewhere. If Merthyr Tydfil is 3° 22′ 41″ West of Greenwich, this, in time, = 13min. 30·733sec., and we say 60m. : 13m. 30·733s. : 9·8565s. : 2·22s. The sidereal time at Greenwich mean noon on Jan. 1 is 18h. 42m. 43·51s., and this + 2·22s. = 18h. 42m. 45·73s. The Right Ascension of α Orionis on Jan. 1 is 5h. 49m. 47·91s. If from this we take 18h. 42m. 45·73s., we get 11h. 7m. 4·40s. as the sidereal interval after mean noon of that star's southing at Greenwich, and this = 11h. 5m. 15·12s. p.m. G.M.T. If, again, from 5h. 49m. 47·91s. we take 18h. 42m. 45·73s., we get 11h. 7m. 2·18s. as the sidereal interval after Merthyr Tydfil mean noon at which α Orionis will south, and this = 11h. 5m. 12·90s. p.m. local M.T. At this instant it is obviously 11h. 18m. 43·63s. at Greenwich itself.

A. B. H.—Do not know of any French journals which are at all "corresponding." Nothing of the kind in France or Germany. That is probably why we have so many correspondents from the Continent. You could put the question to Mr. D. Nutt, Strand, W.C. (sufficient address); he would know about all the likely publications.

MARINE ENGINEER.—To obtain a certificate as a marine engineer you must have had at least twelve months' experience in the engine-room "on the watch" at sea. See "Wannam's Marine Engineers' Guide," published by Crosby Lockwood and Son, Stationers' Hall-court, E.C., price 8s. 6d. That will supply all the information needed, and give some useful hints about the examination papers. Candidates must have had experience in engine-shops on shore, and, above all, have had at least a year at sea in the engine-room "on the watch." That is indispensable.

THOS. W. WHITELEY.—If you have tried all the remedies for creaky boots which have been given in back vols. without success, perhaps you had better take the boots to the shoemaker, and ask him to lift the sole and put some French chalk underneath. As a rule, a number of short rivets driven into the sole at parts effect a cure.

G. HUDSON.—If you refer to p. 18, Feb. 18, 1898, No. 1717, or to p. 158, No. 1723, you will find full accounts of the composition of acetylene. It is a hydrocarbon with the formula H_2C_2. It is mentioned in any good textbook of chemistry—not exactly a novelty. Calcium carbide is the cheap source of supply. That probably explains the cause of your surprise.

W. BRADLEY.—That is the correct address, we believe. We know no other.

SIGNAL.—Get the "Railway Directory," published by McCorquodale and Co., Cardington-street, N.W.

L. C. W.—The advertisers referred to say they have never refused you the piston or the return of your money, but have repeatedly told you they were out of stock. They say they have now returned you the 1s. 6d. sent.

E. CATCHPOOL.—The best source of information of that kind would probably be the secretary of the Royal Meteorological Society, Victoria-street, Westminster. As to rainfall, the records are no doubt in the library of the Society. For the British Isles, Mr. G. J. Symons, F.R.S., Camden-square, N.W., has published for many years records of rainfall. The Governments of the United States, of India, and of Australia, also publish official reports. Possibly all such reports for "twenty years" can be found at the British Museum.

PIERCIE PICKERILL.—Not so far as is known, but you will find something on the subject in the back volumes under the head "Argentaurum."

JOSEPH H. ROWNEY.—Probably of any of the makers of balloons, and possibly also already prepared to resist water and gas. The technical query is inserted.

CHARLES MCARTHUR.—Luminous paint was described many years ago; but as to where to obtain it in the commercial way, we do not know. It was advertised as Balmain's Luminous Paint. It requires exposure to light, and then "glows" for hours. It is mainly a phosphide of calcium, and is mentioned in all the textbooks, some of which you can see in the free libraries of Glasgow and probably also the back volumes of this paper, in which its history has been fully described.

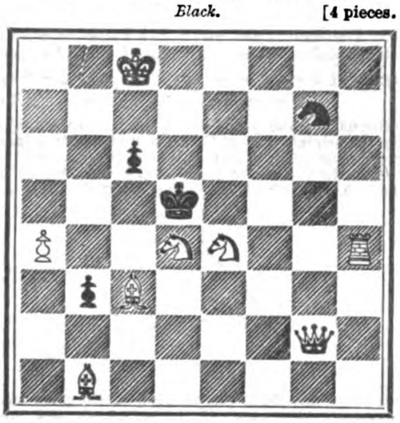
W. A. JENNER.—Such questions should be put to the tax-collectors of the district, in the first instance, and then to the representatives of the local authority or of the county council. The "license" applies only when the vehicle is used as a conveyance plying for public hire. As to the storing and selling of inflammables like petrol, you must consult the local authorities, because they have by-laws.

CHESS.

All communications for this column to be addressed to The CHESS EDITOR, at the Office, 332, Strand.

PROBLEM No. 1708.—By G. B. VALLE.

Black. [4 pieces.



White. [8 pieces.

White to play and mate in two moves.

(*Solutions should reach us not later than Jan.* 15, 1900.)

Solution of PROBLEM No. 1706.—By V. KRAUSE.

Key-move, Q-Q R 2.

NOTICES TO CORRESPONDENTS.

PROBLEM No. 1706.—Correct solution has been received from W. E. Collins, Rev. Dr. Quilter, Richard Inwards, Whin-Hurst, Oracle, A. Tupman, J. E. Gore, Quizco, N. M. Munro, F. B. (Oldham), Frank Gowing.

N. M. MUNRO.—Correct solution of No. 1705 received.

F. GOWING.—In yours of 30th you ask us to point out where your key-move B-K B 6 fails in No. 1704. We are glad to say that it does *not* fail. It is the correct solution, and in "E. M." of 22nd ult. we acknowledged you as one of the correct solvers. What more would you have?

The Chess Editor heartily reciprocates the many kind wishes from his correspondents, and hopes that a Happy New Year may be the lot of all his little band of ardent solvers.

SPECIAL OFFER.—CHEAP VOLUMES.

In the course of the next few months we are compelled, owing to the making of the new street from Holborn to the Strand by the London County Council, to remove our Offices and Printing Works. Due notice of our removal will be given shortly. In the mean time, to reduce stock and save trouble of removal, we offer readers desirous of making up sets of back volumes *any volume* in the list below at HALF PRICE, or post free for 4s. 1d.

Any reader desirous of making a free library or working men's club a present of a few sets of volumes will find this a favourable opportunity. The offer is only available till our removal.

TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

5s. 6d. for Six Months and 11s. for Twelve Months, post free to any part of the United Kingdom. For the United States, 13s., or 3dol. 25c. gold; to France or Belgium, 13s. or 16f. 50c.; to India, New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-Office Order. Back numbers can also be sent out by the ordinary newspaper post at the rate of 3d. each.

Vols. IV., V., VI., VII., XII., XIV., XXIV., XXX., XXXII., XXXVI., XXXIX., XL., XLII., XLIII., XLIV., XLV., XLVI., XLVIII., L., LI., LII., LIII., LIV., LV., LVI., LVII., LVIII., LIX., LX., LXI., LXII., LXIII., LXIV., LXV., LXVI., LXVII., and LXVIII., bound in cloth, 7s. each. Post free, 7s. 7d.

Indexes to Vol. LI., and to subsequent Vols., except Vols. LIII., LV., LVI., LVII., LIX., LXI., 3d. each, or post free 3½d. Cases for binding 1s. 6d. each.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each post free from the office (except index numbers, which are 3d. each, or post free 3½d.)

NOTICE TO SUBSCRIBERS.

Home Subscribers receiving their copies direct from the Office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a PINK Wrapper, as an intimation that a fresh remittance is necessary if it is desired to continue their subscription.

Foreign Subscribers will have the Pink Wrapper sent ONE MONTH before expiration, in order to give them time to forward fresh remittance before subscription expires.

The English Mechanic
AND WORLD OF SCIENCE AND ART.
FRIDAY, JANUARY 12, 1900.

A SMALL MOTOR-CAR, AND HOW TO BUILD IT.—II.

FIGS. 2 and 3 show two views of the motor complete. It will be seen that this is of very simple construction. As far as practicable, forgings have been replaced by malleable iron castings. The only forging of any difficulty is the crank-shaft. The numbers refer to both views, the references being:—1, the cylinder; 2, the cylinder-cover; 3, the crank-chamber fitted with covers 4 and 5. The cover 5 has a boss (6) on it, which takes the stud 7 carrying a sleeve 8, on which is formed the exhaust-valve cam. This sleeve has keyed to it the gear-wheel 9 driven by the pinion 10, which is keyed to the crank-shaft 11. The wheel having twice as many teeth as the pinion revolves at half the speed of the crankshaft, thus operating the exhaust valve at every alternate in-stroke of the piston. The piston 12 is provided with three packing rings (13) which make it a gas-tight fit in the cylinder. The connecting-rod 14 is a malleable-iron casting fitted with brasses at each end. On a facing cast on the side of the cylinder is bolted the valve-box 15, which communicates with the combustion-chamber of the cylinder by the port 16. The valve-box has a water-jacket which opens into the cylinder water-jacket, thus keeping the valves and seatings at an even temperature. The inlet-valve, 17, is automatic in its action, opening by the suction of the piston, and returned and held to its seat by the light spring 18. The exhaust-valve, 19, is furnished with a stronger spring, 20, which resists the suction-stroke, and is lifted from its seat every second revolution of the engine by a cam on the sleeve 8. This cam raises the roller 21 on the bell-crank lever 22, pivoted at 23, the other arm of bell-crank lever having the push-rod 24 jointed on to it. This rod pushes up the exhaust valve. On the face of the gear-wheel 9 is a disc, 25, both gear-wheel and disc being formed of vulcanised fibre in one piece. On the edge of the disc is the brass segment 26 in metallic connection with the sleeve 8. On the projecting end of the stud 7 is mounted a fibre plate on which is a brush or spring bearing on the fibre disc. As the primary circuit of the induction coil will have one wire earthed on to the motor and the other connected to this brush, at every revolution of the fibre disc the brass segment will be brought into contact with the brush, thus completing the circuit and causing the ignition of the charge. To

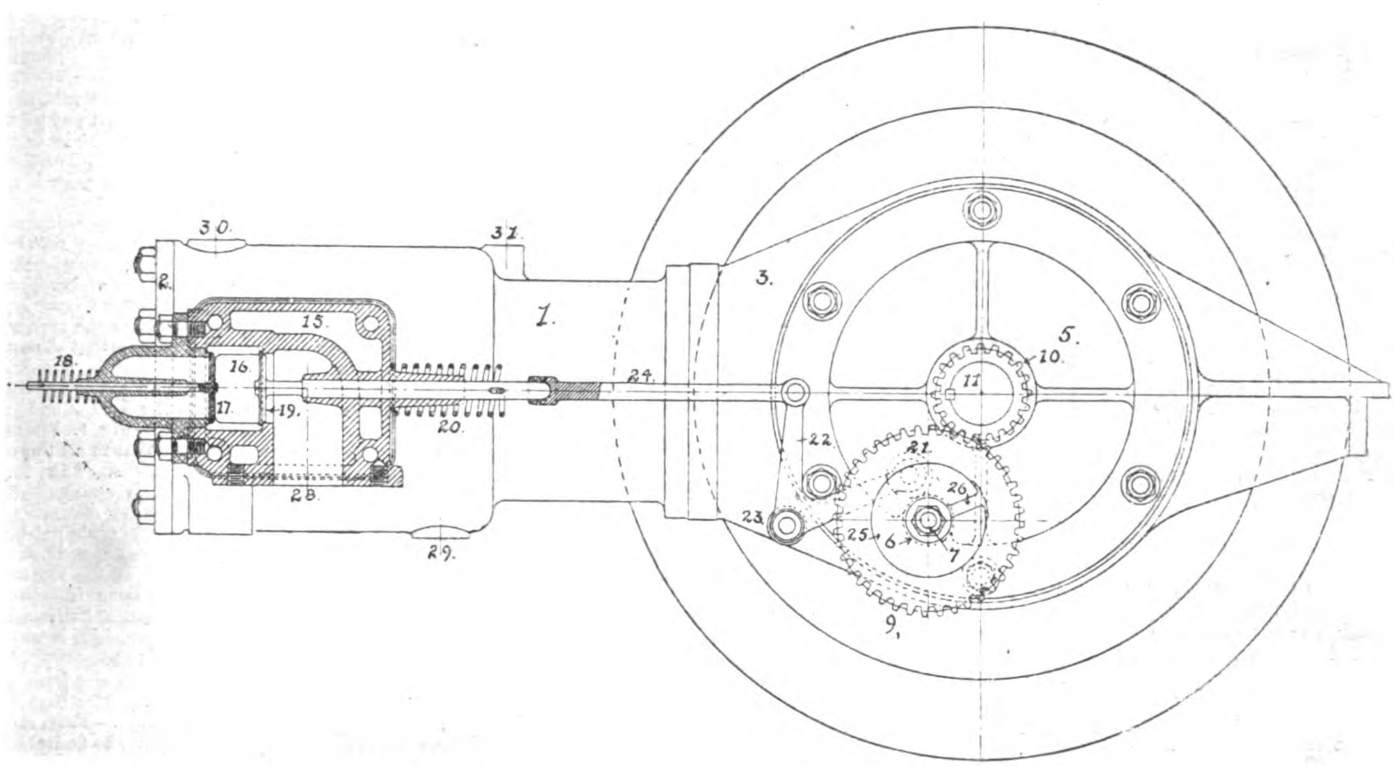


FIG. 2.

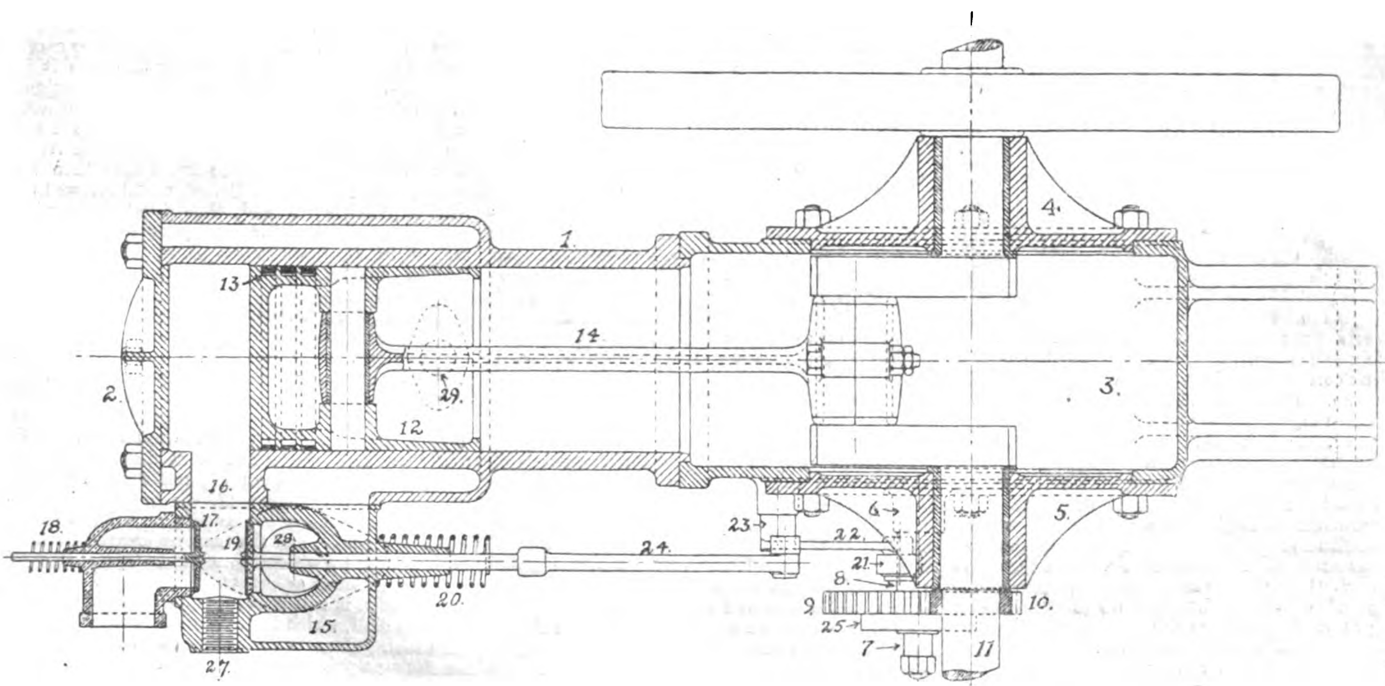

FIG. 3.

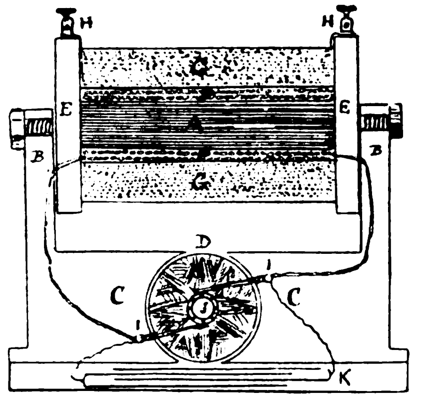
avoid confusion, I have omitted the fibre plate and brush in Figs. 2 and 3. The sparking plug will be screwed into the valve-box at 27. The exhaust gases pass away to the silencer through the hole 28. The water for cooling the cylinder enters the jacket at 29, and leaves it at 30, an oval facing being cast at these points to which the flanges on the water-pipes are secured by studs and nuts. A sight-feed lubricator for the cylinder is screwed into the boss 31. To insure the lubrication of the sleeve S and the fulcrum of the bell-crank lever at 23, the studs carrying these are drilled up from the inner ends, a sufficient quantity of oil being splashed into these holes by the crank, whence it is led by smaller holes on to the bearing surfaces. There is also provision made, as will be seen later, for continuous lubrication of the crank-shaft bearings. All the bearings of the engine and valve gear are thus lubricated automatically—a matter of considerable advantage in a motor carriage where the neglect of oiling one bearing may cause it to seize, and land one miles from home with a car that will not work. In order to enable one to adjust the big end of the connecting rod without having to take off the covers of the crank chamber, a hand-hole covered by a plate is made in the crank chamber in its upper side. As the motor is to be as simple as possible, I have not shown a governor on it; therefore, to prevent the engine from racing when the car is stopped, use must be made of the throttle-valve, which will be bolted to the dome-shaped cover of the inlet-valve. As a governor is a great convenience, reducing as it does by its action the number of levers to attend to when making a stop, I propose showing later on how one may be fitted by which the speed of the engine may be prevented from exceeding a given limit. The inlet and exhaust valves are of ample area to insure free working without throttling the incoming charges or causing back-pressure on the exhaust stroke.

A NOVEL DYNAMO-COIL.

MESSRS. BOTTONE AND SON, of Wallington, have secured provisional protection for a new form of dynamo-coil, which promises to be of great service in many branches of electrical work, such as igniters for gas and oil-engines, the production of current at very high E.M.F. for X-ray work, and, in point of fact, in all cases where a quick and easy mode of setting up high-tension electricity, without the use of batteries, accumulators, or a separate dynamo is required. On the battle field, for radiographic work, this apparatus will prove itself invaluable, as it is portable, easily driven, and not nearly so heavy as coil and accumulators. Our illustration gives a good idea of the general construction. A is a soft iron wire bundle, which serves at once as the core of the coil and the field-magnet of the dynamo. This is wound with wire suitable to render the machine an efficient series-wound dynamo, and at the same time to impart magnetism to the core as a primary coil. This wire is shown at F F. Thence the wire is led to the brushes I I, whence the current generated by the armature D is picked up. The commutator J is constructed specially to give sharp interruptions in the current. No contact breaker is therefore needed. G G are the secondary coils, the terminations of which are brought up to the binding screws H H. B B are the yokes, and C C the pole-pieces of the dynamo proper. A condenser, K, is in circuit with the brushes.

In our illustration neither bearing nor pulley is represented. On rotating the armature at its proper speed the machine enters into action as a dynamo, and, in so doing, at each interruption of the current, which occurs as the slits of the commutator pass under the brushes, powerful currents are induced in the secondary coil, which currents can be taken off the secondary terminals. So efficient is the apparatus that one of these dynamo-coils, standing 7in. high by 7in. wide, and 5in. deep, and weighing only about 12lb., will give a continuous and fat ½in. spark from the secondary terminals, the entire machine occupying actually less space, and being of less weight than that of the accumulators usually employed to work an ordinary coil of the same output. The winding of both portions of the machine can be varied at will to produce different effects; hence it is possible to adapt the machine



to the production of soft, steady currents for medical purposes, or to the generation of hot "quantity" sparks for gas or oil-engine ignition, or, finally, to the evolution of high frequency discharges of enormous tension, but small ampèrage, for X-ray and wireless telegraphy effects.

ORNAMENTAL TURNING.—XXXIV.

By J. H. EVANS.

AS intimated in my last, I now have the pleasure to illustrate and give the details of the specimen of work executed by the aid of the slide-rest, which has occupied our attention through four or five articles, and to those who have finished, nay commenced, the task of making this instrument, I offer my hearty congratulations. These may not be, in fact are not, worth much; but with them goes the corresponding desire to give all the further help I can; so I say no more than, to all questions I am ready to give the fullest information, hiding nothing; knowing no more than I have told, and hoping for nothing but that the very best results may reward the amateur who is bold enough to have undertaken the task.

The vase shown in the illustration not only gives an idea to copy and improve upon, but at the same time further illustrates many different applications of the spherical slide-rest, which, I may say, have not yet even come under our notice. I may as well here candidly confess that, much space as I have occupied, it would entail the filling of even many entire numbers of the "E.M." were I to attempt to show all and everything that could be done with this particular tool; but the following explanation of the specimen before us will enable those interested in it to follow, and discover what I am unable under the circumstance to further dilate upon.

The vase, as here depicted, may, of course, be either enlarged or reduced; also it may be made of different materials. That from which the autotype was taken is made of boxwood only, which arose from the fact that when I commenced it I intended only to carry out some experiments in connection with the spherical slide-rest; one part after another turned out a success, and so I determined to complete the whole thing in the same material. I must say that after the amount of time and labour I expended upon it, I rather regretted I had not made it in ivory; however, in all respects, it was all I could desire.

I should strongly recommend turners to always make their first attempt in this particular wood; but when about to produce a finished specimen, it should be made either of ivory or blackwood, or a combination of the two is most effective. I have seen three different copies of the vase now illustrated: one composed entirely of ivory, a second in African blackwood, the third being a combination—that is, the base being of blackwood, while the tazza and stem is in ivory, and, as a matter of fact, it was a difficult task to decide which I really preferred, all being equally beautiful; however, I think the ivory had the preference. There are reasons why it is not always available, and the choice of material must be left entirely to the turner who is about to execute the work.

The first attempt to reproduce a piece of work of this nature may not result in an exact copy. This is scarcely to be expected, as the instrument is in itself complicated, and it will require some practice to overcome the difficulties of such an intricate piece of machinery. This, however, is more or less modified by the explanation of its manufacture and manipulation in the previous articles upon the subject.

When about to commence such a piece of work the proportions must first claim the attention of the operator, and the material, whichever it is, must be selected with equal care as to size, colour, and grain.

Should it be desired to produce a fair copy, the dimensions of the original are as follows: 12½in. high, the tazza or bowl 5½in. in diameter. Should any of the material selected fail to turn up to the required size, it must be at once discarded and replaced by fresh. It is the idea that one piece being a little small will not matter: that leads to disaster in the finish, and if the sizes of the various parts be not maintained, the result cannot be satisfactory.

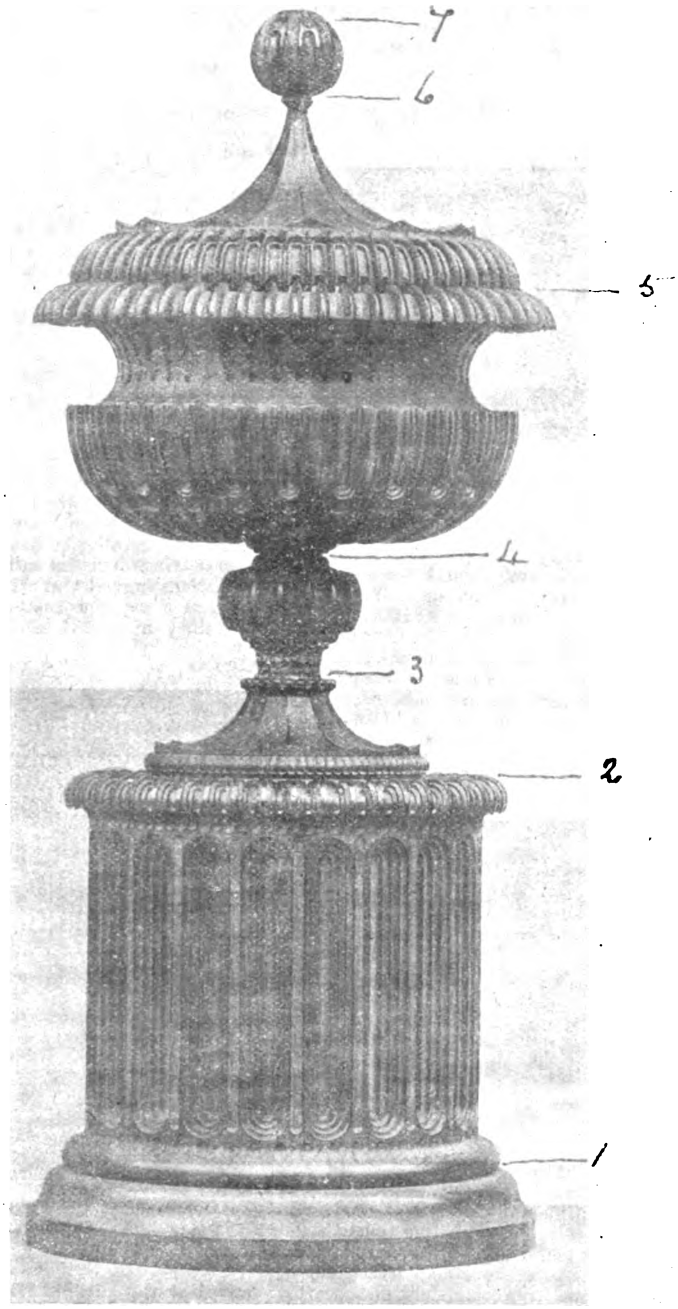
In making these remarks, I do not presume to imply that the base I illustrate may not be improved upon by many of our experienced amateurs who may read this; the observation simply refers to the production of a true copy. The choice of material being left to the turner, I will, as a basis, assume that ivory is that chosen for the work, and we will commence at the foundation—viz., the base. This is composed of a plain ogee. This should be cut from the hollow end of a tusk, and the thickness as shown, Fig. 1. I have numbered the autotype, showing that in all there are seven distinct and separate pieces. This, for the reason that much material is economised, labour saved, and the facilities for decoration much enhanced, in fact, some parts could not be done if the whole of the upper part were in one piece—I mean, of course, as far as the top or cover. The measurement may be taken from the illustration, as it is as nearly as possible half-size, so if it should be considered large enough, it may be made to the dimensions existing in the copy.

The body, 1 and 2, must be cut also from a hollow, but of lesser dimensions. The base 1 may be best held in the following way:—From the unevenness of the interior, it may not be desirable to turn it out true; anyway, it is not necessary. In this case, a boxwood chuck should be turned down to allow the ivory to pass freely over it, to admit of the external diameter being as nearly true as possible. The ivory must then be carefully faced on one side, and by this face it is securely held to the boxwood with strong glue. When dry, the ogee moulding is carefully turned, and being perfectly plain, may be shaped by hand. This, it will be noted, is the only portion that is entirely plain; the front may then be turned out to a suitable diameter, and screwed to receive the body 2, and, thus fitted, it may be considered chucked for further operation, being turned in its permanent place, therefore no further chucking will be required.

The body is now turned to a short cylinder. To do this, the ornamental slide-rest may be used, and as a matter of preference I should recommend that it be so, as it will be as well to save the more delicate rest all the work possible. However, as I have already stated, this was done entirely with the spherical slide-rest. I will explain it as so:—The top slide must be turned round to front the work, then fixed with the binding screw of the socket, and the third slide set parallel with the second, the top slide is (for rigidity sake) kept as much over the worm-wheel as possible, and the traverse created by the second slide, by which the work is turned to the before-mentioned cylinders.

The body, it will be seen, is fluted with a large size step drill, which is substituted in place of the fixed tool. Here is an instance of the necessity for fitting a pair of fluting-stops to each slide, as previously recommended. This must be set one on each side, to meet the requirements as to the termination, the flutes at the ends. The flutes being deeply cut and of increased sizes, each one will require a series of cuts to complete it. Also, when working round a large diameter of this material, it may reasonably be expected that the drill will lose a deal of its clean-cutting powers; therefore, when one round has been completed, the drill may be removed and very carefully sharpened.

The best way to effect this is either by means of



piece of Arkansas stone, with a sharp square edge or a series of brass slips, also made sharp, for the fillets, and curved for the various profiles. The same will require to be made with concave and convex: they should be fitted into convenient handles, and when used, charged with crocus and oil, the tool held in the left hand, while the slip is applied with the right, care being exercised to keep the brass flat on the vertical angle. The face of the drill must, of course, not be touched, beyond what is required to remove a slight burr should any have been created.

With the drill thus sharpened, a final cut may be taken over each flute; it is, of course, not impossible, but somewhat probable, that, in the process of sharpening the exact profile of the drill may have been slightly altered; this, however, will not interfere with the result, as a slightly increased penetration will again render it perfect. Between each flute sufficient space is left for a round-nose drill to be inserted. The original being 4in. in diameter at this particular part, contains twenty-four. The deeply-cut step flutes are cut by the smaller round-nose drill, being placed to cut between each; at the two extremities a round-nose drill is again used to pierce or serrate the corresponding hollows at each end; the lower curve having two drills employed alternately as seen in the illustrations.

We now arrive at that part of the work which affords the first instance of the application of the spherical slide-rest, and this is contained in the curved lip at the top of the body we have just fluted. The curve may be carefully shaped by hand approximately; the spherical rest is then placed on the bed of the lathe and fixed, the main slide is now adjusted to coincide with the lathe axis, and the slide which carries the worm-wheel so fixed as to place the latter exactly under the curve to be turned. This will at first be found rather a tedious and troublesome job, but a few trials and short experience will soon obviate any difficulty in this respect. When thus set, the work is first turned in plain form, which will be found to take much less time than the the settings and adjustment occupied. The drilling instrument again replaces the fixed tool, and with a smaller size step-drill this curved lip is fluted to correspond with the other parts.

It will be observed that the curved form is carried completely over the top. If it is found that the drill will not traverse over the curve far enough to cover the distance, it may be adjusted to do so by moving the tool receptacle on the socket; but on no account must the position of the worm-wheel be disturbed.

The difference between the positions of the fixed tool and the drill will arise from the fact of the plain form being turned with a curved tool while the drill is central to the stem of the instrument. The distance to be traversed once decided, the segment stops are employed to certify the same for each consecutive cut. So far we may consider the base and body complete. Before removing it, however, a recess must be turned out, and screwed to receive the foot of tazza.

The foot No. 3 should be first roughed into shape by hand, and screwed to fit the recess in the body to which it is to be attached. It must then be fitted to a well-seasoned boxwood chuck, and, as a matter of security, it is a good plan to place a little thin glue between the faces. This is not absolutely necessary, and, if the fitting is well made, it may be omitted; but in the case of any excessive excavation being required, it is always a safeguard against the work moving in the chuck.

The concave curve thus approximately shaped, the spherical slide-rest is again adjusted, and the tool in this case extended beyond the centre to suit the curve, which is then turned; we now cemo to the application of the vertical cutter in place of the drill. This is placed in the tool-box, and by shifting the same in the socket, the cutting-edge of the tool is brought to the necessary position, by which it will follow the curve already turned by the fixed tcol. The vertical cutter with the spindle passing through to one side is the most suitable for application in this rest, as there is no framework to prevent the tool passing round the curve or come in contact with any shoulder on the work or face of the chuck. With the tool adjusted twelve consecutive cuts only are made. At the base of this foot, it will be seen is a small serrated moulding cut with a drill, and at the top, a series of small beads. These are better cut with an astragal or square-end bead-tool, in order that, when finished, the beads stand well apart. The intermediate piece 4 is carried out in a similar way, being first shaped by hand, and afterwards decorated as shown.

We have now arrived at that portion which may be considered the most difficult, and forms, so to speak, the most important feature of the design. This is all in one piece, which to a great extent creates a difficulty in its execution. The rough block of material is held in a Universal chuck. The inside is then first excavated. In the first instance, a short, slightly taper fitting should be left. It is then removed from the jaw-chuck, and rechucked carefully upon a boxwood plug by the inside fitting referred to. Here again the application of glue will be found an assistant, especially if the work is likely to remain for any length of time upon the chuck unfinished.

The lower convex curve forming the bowl is next shaped approximately, followed by the concave curve at the upper part receiving the same treatment. The spherical rest must again be very carefully adjusted to the precise axis of the lathe. This setting is not a difficult matter in any case, seeing we have the index-line already marked upon the lower slide. This done, the second slide must be brought into use, to place the axis of the worm-wheel exactly under the hemisphere or curve to be turned. In this case a straight tool will be found to travel far enough round the curve to meet our requirements.

Again is the drill substituted for the fixed tool, and in this case a step-drill of smaller dimensions than that used for the body. As the drill passes out at the upper part it will only be necessary to adjust one segment step to arrest the cut towards the centre. Around this bowl there are forty-eight consecutive cuts, half of which are first cut—viz., those that go throughout the curve to the centre. The intermediate incisions, it will be seen, are arrested at half the distance, in order that the true form of the curve be not destroyed by their too close proximity at the centre. This admits of a series of round-nose drills of different sizes being used to stud seriatim over that part left uncut. It is scarcely necessary to point out that, when about to cut the intermediate step flutes, the segment stop of worm-wheel must be readjusted, to prevent undue traverse in that direction. It is found in practice that a great deal of the superfluous material may be removed by the partial rotation of the circular movements by hand; but for finishing cuts, the tangent screw should be placed in gear, and the motion governed by it.

The second slide must next be adjusted to suit the concave curve beyond the one we have just turned; this will require a careful and precise setting. Once more is the drill spindle resorted to, and a series of different sized round-nose tools employed to decorate this form. The work is now removed, and chucked by the edge of the curve bowl. Here, again, much care will be required. It will be noticed that it is held in the chuck by the uncut spaces on the body. It

will, however, hold perfectly tight if correctly fitted to the chuck. Thus held, the convex curve is turned, and the spherical rest adjusted to suit the curve. This curve is decorated with a series of reeds, which are cut with a quarter-hollow drill having an astragal end, thus creating the space between each, as seen in the illustration. As in this case the distance at which the drill was arrested between each reed did not allow the true form of the hemisphere to result, the reeds take an elliptic form, which adds to, rather than detracts from, its appearance.

So far, the specimen is complete, with the exception of the cover. I have heard it expressed that the latter is not an improvement. This may, at the same time, be considered a matter of opinion, and any turner deeming it worthy of reproduction can omit this part or not, according to taste. The proceeding for the shaping and decorating of this part is almost identical with those already explained. I may mention that the cover is not intended to fit closely, the spaces rendering the vase appropriate in a *pot pourri*.

I have, I hope, now given all the details necessary to enable a turner of some experience to either reproduce this as shown, or to improve upon it, as the notes with respect to the movements of the spherical slide-rest are more or less the same throughout its application to works of all kinds.

I have received more than than one request to treat next the spiral apparatus, which I propose to do, also with illustrations of rudimentary examples of work, ending with complete and finished specimens.

THROUGH A SMALL TELESCOPE.—IV.

By NORMAN LATTEY.

RESUMING our examination of the circumpolar constellations and those which are approaching the horizon in their annual drift westward to disappear for the season, we begin our work this evening with Aquarius (the Water-Carrier), lying immediately beneath the celestial Equator, and about to set in the south-west. There is a beautiful planetary nebula (No. 4628 in Klein's Atlas, position R.A. 20h. 58m., S. Dec. 11° 50') in this constellation, close to the star ν. It was discovered by Sir William Herschel in 1782, and is sometimes called the "Saturn Nebula." 41 Aquarii is another pretty double, composed of a yellowish star of 5½ mag. and a tiny companion nearly 9 mag. Almost immediately over this little object is ζ Aquarii (Fig. 1), a tolerably close double; but the components are fairly large and of almost equal magnitudes—viz., 4 and 4·1. Both are pale green. Yet one more easy double, fairly wide apart, is ψ Aquarii, with its deep yellow primary and blue companion.

Above Aquarius towards the zenith stretches the extensive constellation of Pegasus (the Winged Horse). ϵ Pegasi, a wide double, is a fine 2-mag. star, with a companion 8-mag., the latter another of Sir W. Herschel's many discoveries. η Pegasi, of 4 magnitude, with a minute companion 11 magnitude, affords a severe test for both a 3in., and the eye looking through it, in the detection of the *comes*. β Pegasi is a fine variable of 2 mag. with a faint companion. Its variability is, however, almost imperceptible as well as irregular; but it is accompanied by a slight change in the reddish tint of the star. An instance of a multiple star is furnished by γ Pegasi; but the two companions are hardly visible in the aperture at our disposal.

Between Pegasus and the cross of Cygnus is the small diamond-shaped group constituting Delphinus (the Dolphin). β, the most southern of the four, is a fast-moving binary, the components of which revolve round each other in about twenty-eight years. The spectrum yielded by the light of this star is remarkably similar to that of our sun; but computations go to show the former must be at least seven times brighter.

Higher up, towards Polaris, is located the minor constellation Cepheus in which are a number of fairly easy doubles, among them β (Fig. 2), pale green and of 3 mag., its small violet companion a little way off. Almost due south of this and almost in the middle of the diamond formed by α β ι, and ζ Cephei will be found a dense star cluster, a pretty spectacle even in a small telescope. δ Cephei is a yellowish-red variable, and the primary of a wide double-star system in which the companion is blue. Besides being a variable, with a period of 5d. 8h. 48m. δ Cephei is also, in itself, a "spectroscopic double"; but its minute *comes* is probably a dark body, as it is quite invisible to direct vision. ζ Cephei is another double, though somewhat close and difficult to divide; while μ Cephei, the ruddiest star in the Northern heavens, has also a minute companion.

Adjacent to Cepheus towards the east, the

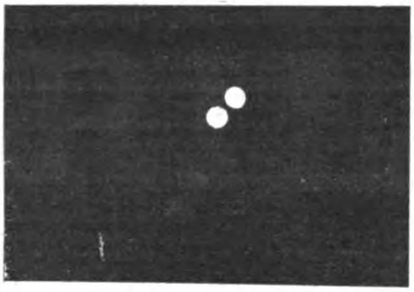


FIG. 1.—ζ Aquarii.

prominent W formed by the principal stars in Cassiopeia (the Lady's Chair) form a striking figure. Among the first objects we encounter about half-way between this constellation and Cepheus is a star cluster (No. 4957 in Klein's *Atlas*, but erroneously stated in the text to be in Cepheus). Close to β Cassiopeiæ (a star of 2½ mag. with a faint companion) is another star cluster; but it needs a large aperture to show it well. Several more occur between β and γ Cassiopeiæ. In fact, in this as with all the groups lying in the neighbourhood of the Milky Way, the entire

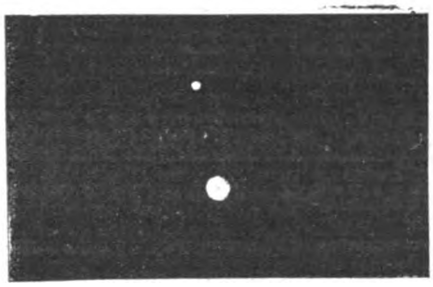

FIG. 2.—β Cephei.

region is crowded with clusters scattered and dense. γ Cassiopeiæ, lying in a field strewn with stars, has a companion 9½ mag., some considerable distance from it. It was in this constellation that the famous temporary star observed by the Danish astronomer Tycho Brahe blazed out in 1572 A.D. It long ago completely disappeared, yet it may be of interest to examine the place it once occupied. The approximate position is R.A. 0h. 19m. N. Dec. 63° 24'. η Cassiopeiæ (Fig. 3) of 4 mag. is yellowish with a 7½ mag. purple companion. It is an interesting binary with a period of 200 years. Special attention may be drawn to a star cluster immediately south of the star ϵ. Not only is it large and rich in stars; but a

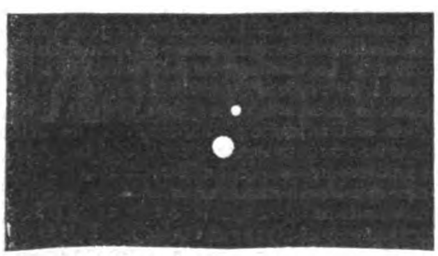

FIG. 3.—η Cassiopeiæ.

double and red-coloured star (both about 8 mag.) are to be seen in its midst.

To the immediate south of Cassiopeia stretches the attenuated form of Andromeda, containing one of the most famous objects in the Northern heavens, the Great Nebula (Fig. 4), a weird elliptical patch of hazy light shining with a strange translucence. Its ellipticity is, however, doubtless due to an effect of perspective, for it is in all probability nearly circular—a colossal maelstrom of glowing gas viewed almost edgwise. Its position is easily discerned even with the naked eye, being quite close to ν Andromeda, the most northerly of the two small stars lying at right angles to β Andromedæ (shown in Phillips' "Planisphere"). A reference to the atlas will at once make its exact situation clear (R.A. 0h. 36m., N.Dec. 40° 35"). An opera glass will show it distinctly, and a small telescope easily reveals its nebulous nature. In a 3in., on a dark, clear night, it is a splendid sight, the observer's wonder deepening with steady gazing into its mysterious depths. A few facts regarding this celestial wraith may be interesting. The existence of the nebula has evidently been known since the 10th-century. Messier noticed an increase of brilliancy towards the middle; but even the highest optical power of to day cannot resolve it into stellar points. About the end of August, 1885, a star of 6½ mag. suddenly appeared near the centre; but in a fortnight dwindled down to 8½ mag., and by the following summer had disappeared altogether. There are several small stars scattered throughout the length and breadth of the nebula; but they do not seem to have any physical connection with it. The well defined dark rifts on each side of the brighter portion are in all likelihood vacant spaces between the rings of matter surrounding the nucleus. Calculations suggest that the entire structure is a vast mass of vaporous matter partially condensed into a fluid or viscous condition, though not yet

FIG. 4.—The Great Nebula in Andromeda.

arrived at the present stage of our sun. The distance of the object is difficult to determine. Estimates have been made amounting to five times the distance of α Centauri, the nearest star to the Solar System, a distance that can only be measured by 650 light-years! Our luminary removed to such a remoteness would pale to the insignificance of an 11th-mag. star. Close by is another nebulous looking object commonly called the "Companion of the Great Nebula." It is, however, a star cluster which requires considerable power to resolve. μ Andromedæ (the lower of the two smaller stars marked on the planisphere) is worth a few minutes' scrutiny, as its tiny companion of 11 mag. affords another severe test of excellence both of eyesight and instrument. It really needs a powerful telescope to see it well. Not so, however, that exceedingly pretty and comparatively wide double γ Andromedæ (Fig. 5), a specimen almost as fine as ζ Ursa Majoris, with its beautiful gold and greenish-blue components. The colours of both stars are very intense. They really form a triple system, the primary itself being a close double, far beyond the separating power of our modest aperture.

Beneath Andromeda lies another straggling constellation, Pisces (The Fish), in which are several interesting doubles, all well within the range of an instrument of 2in. or 3in. Among them may be mentioned Nos. 35, 51, 55, and 65, all of which are marked on Klein's atlas. Special allusion may be made to ζ, a lovely double, easy to see with its components of 5 and 6 mag. Its position (R.A. 1h. 8m. N. Dec. 6° 56') is slightly to the east of ϵ Piscium.

Almost wedged in between Andromeda and Pisces is the lesser constellation Aries (The Ram), which gives its name to the first sign of the Zodiac, although, owing to the precession of the Equinoxes, this group no longer exactly corresponds with that sign, as it did in the time of Hipparchus when the sign was named. Not far below the smaller of the two principal stars

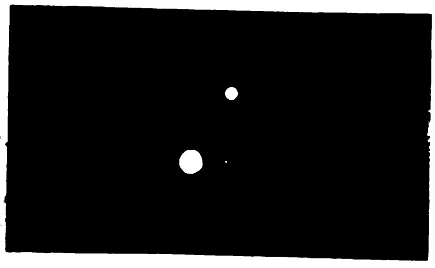

FIG. 5.—γ Andromedæ.

(shown in the planisphere, and by the aid of which they can be easily identified in the sky) lies γ Arietis (Fig. 6), an historical double, inasmuch as it was one of the first to be telescopically observed by Hooke in 1614, who remarked that "it consisted of two small stars very near together, a like instance of which I have not else met with in all the heaven." The smallest telescope, almost, will divide its two nearly equal components of 4·2 and 4·4 mag. Just above α and β Arietis may be found λ Arietis, another easily-divided double; but its companion, being only 8 mag., is not very prominent.

About the same distance still further north of α Arietis lies 14 Arietis, a triple star with a primary 5½ mag., and two tiny companions. It is well worthy of inspection, and will afford us a convenient example with which to close our investigations until next week. Probably, too, by the time the student has examined these three last constellations he will have had enough of astronomy for one night, if indeed he has not succeeded in completely dislocating his neck in his endeavours to look upwards through the, by now, almost vertical tube. He may, however, derive some small consolation from the knowledge that if uncomfortable to observe he has been seeing these objects in their best possible positions as far as clearness and good definition are concerned; for celestial bodies need to be placed on or near the meridian, high above the dense horizonal mists and sluggish atmospheric strata which lie close to the earth's surface, in order that the more delicate minutiæ of both planetary and stellar detail may be fully revealed. Obviously, if we are gazing directly overhead, we are looking through a lesser thickness of fog and smoke than if our vision were directed more obliquely to objects of a lower altitude.

One or two of the illustrations in the last article did not reproduce quite as expected—viz., the star cluster in Hercules, which came out too bright, and the "double-double" ϵ Lyræ, which should have been much reduced. The views this week have, however, been drawn exact size to

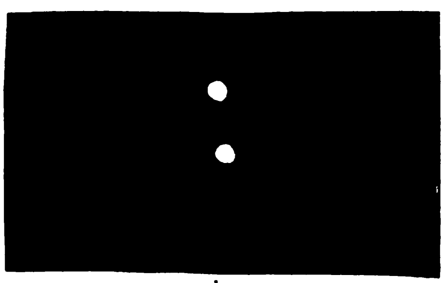

FIG. 6.—γ Arietis.

fixed scales, both of magnitude and distance, which will be adhered to as far as possible throughout these papers, although it will necessitate making the star discs of the higher magnitudes seem rather larger than they appear in the telescope, in order that pairs with very small companions may be portrayed in their correct relations.

The instrument in use is one of Messrs. Thos. Cooke and Son's superb photo-visual refractors of 4in. aperture, stopped down to 3in. Possessors of telescopes of ordinary quality must therefore not feel despondent should they not be able to readily see faint objects quite so clearly as they are drawn. Often, too, the indistinctness may be entirely due to unfavourable atmospheric conditions which frequently render the most perfect lenses almost useless.

SOME METEOROLOGICAL INSTRUMENTS AND THEIR USES.—XI.

AS seen in the measuring-glass of a rain-gauge, the amount of water derived from a moderately heavy shower seems very insignificant, and even one inch of rainfall does not bulk very largely. A fall of one inch does, however, in reality represent a very large amount of water, and the statement that such a fall over any given area means that roughly 100 tons weight of water has fallen on every acre, gives a slight notion of what this amount of precipitation really is. Over an area of the size of the Thames valley, a fall of one inch of rain means that 53,375,000,000gal. of water has been condensed out of the atmosphere, an amount which has to be drained into the main river by the rivulets and streams, and when such a quantity of water as this falls, say, within an hour, it is not surprising that destructive floods sometimes occur. In northern India 10in. of rain once fell in less than two days over an area of 10,000 square miles, the weight of water in this downpour being no less than 7,248,000,000 tons. On another occasion elsewhere 2·34in. of rain fell in thirty-seven minutes, and ·62in. in seven minutes, and where successive falls of rain such as these occur over large tracts of country, it will be gathered from the figures quoted above that the amount, although small in the measuring-glass, may readily be translated into millions of gallons and tons. Given, therefore, the area of the country over which any heavy rain has fallen, it is not difficult to work out how much water has passed into the watercourses and rivers, and to make an estimate as to the quantity of the rainfall available for the feeding and nourishment of the local springs and wells. In this connection, the easily-remembered jingle which says that a pint of water weighs a pound and a quarter will be of service; while, in making other calculations, the recollection of the fact that a cubic foot of water weighs 1,000oz. will have its uses. It has been proposed at various times that in order to prevent floods in the Thames Valley, reservoirs should be constructed to hold the rainwater, and since it is not unknown for 3in. of rain to fall in one day, it will be seen that such reservoirs would need to have a total capacity of 160,000,000,000 gallons. The cost of constructing such reservoirs as these has been estimated at £15,000,000. Now, of course, in these times of great national expenditure, such enormous works as these are not likely to be undertaken; but the figures at least serve to indicate how very great a quantity of water is represented by a tenth of an inch in the measuring glass of a rain-gauge.

Now, the contemplation of the enormous volumes of water represented by the foregoing figures raises the question as to where all the rain comes from, and the attention is soon led to the consideration of the causes which carry the moisture into the air and throw it down again. The prime agents in the production of rain are, of course, the sun, which provides the heat, the ocean, from which the moisture is evaporated, and the atmosphere, which acts as the condenser. From the atmosphere the moisture is condensed in a multitude of ways, and from the violent condensations which occur during some large cyclonic disturbance to the quieter depositions of moisture which happen during a heavy display of hoar-frost, there are plenty of different methods for consideration. It used to be said that rain was mainly produced as the result of two currents of air of different temperatures and of a different humidity coming into contact and mixing with one another, but although this action is in many circumstances responsible for much rain, it has given place to other theories. Dynamic cooling as the result of the expansion of vapour-laden air in an ascending current now finds most favour as a rain producer, and a consideration of the facts leads to the conclusion that meteorologists are right in adopting the newer standpoint. When a moist current of air flows against a range of mountains rain commonly follows, and, according to the old statement, this rain was owing to the fact that the air had been cooled by contact with the cold sides of the mountain; but the newer statement ascribes the rain to the fact of the current of air being thrown upward and reduced in temperature by expansion. The mountain range, therefore, gives the wind a vertical component, and the reduced pressure results in a dynamic cooling, as it is termed, and rain follows.

Cumulus clouds, which so much resemble huge bales of wool, are commonly said to be the tops or capitals of columns of hot, moist air, and when these clouds become surcharged with moisture or are overgrown, then rain falls from them. These clouds may, moreover, almost be said to spring into existence like a bursting rocket, for it is only when the rising stream of air reaches a certain level that the moisture in response to dynamic cooling bursts into cloud. The height at which the condensation takes place is indicated by the long base of the cloud, this level base with the rocky or turreted peaks of clouds above it being, as is well known, the distinctive feature of these cumulus clouds. Such ascending currents as these are called convection currents, and of all the forces which put volumes of vapour in a position to be cooled by expansion, they are perhaps the most important. There is not much difficulty in imagining how the moisture which is thus condensed grows to the size of a rain-drop, and increases in size until it is heavy enough to fall to the earth. In recent years there has been in meterology quite a boom, so to speak, in dust, and whenever condensation of moisture is thought of it is commonly considered that there must first be a tiny atom of dust for it to settle on. Were it not for these dusty nuclei, the atmosphere would be continually raining down moisture, and it is owing to their presence that the condensed vapour is able to float about in the air, and be transported from one place to another. When once moisture has condensed on one of these dusty nuclei a surface is formed on which further supplies of vapour may settle, and the drop gets, as it were, a start in life. But as moisture condenses on any surface, latent heat is of course set free, and some authorities say that this action has the effect of evaporating the very tiny particle of moisture which may be condensed, and the raindrop makes but small progress, or may even die as soon as it is born. All dust nuclei, however, are not alike, and many keep the moisture which settles on them, and sooner or later such favoured drops collide with their neighbours, and in this way increase in bulk and commence to fall. The drops also overtake one another like the bubbles in a bottle of soda-water or like the drops of moisture on a window-pane, and amalgamation goes on apace. Since, moreover, the drops of moisture are very cold, they readily collect more material from the ascending moist current of air through which they are falling, and they eventually reach the earth as a full-sized raindrop. In this connection it may be remarked that if an ordinary school-slate be ruled into a number of squares, some interesting observations may be made concerning the distribution and size of the raindrops which fall during a shower. Some idea of the distance the drops have fallen may be gathered from their size and the force with which they splash on the slate. The rain, then, which falls as the result of these ascending currents is sometimes called convective, and the term is used to indicate that there was but little horizontal movement in the air-currents by which the rain was produced. These convection currents rise from all parts of the earth, but they perhaps occur on the largest scale in the belt of calms at the Equator, and here it may often happen that the moisture which evaporates from any surface returns to the same spot as rain, since there is no horizontal movement of the air to carry the evaporated moisture away to other neighbourhoods.

The great carriers of evaporated moisture are, of course, the cyclones. Not only have these low-pressure systems strong convection currents, but they also have a great horizontal movement, and are indeed much wider than they are high. Rain which falls from these swirling vortices is termed cyclonic, and this forms a large class, and includes thunder showers, which are produced in a variety of ways, and such torrential rains also as occur during what is sometimes termed a "cloud burst." The rain which falls during the cyclones has commonly been evaporated in some distant locality, the rain which is discharged over the British Isles, for instance, from cyclones which come in from the Atlantic being an illustration

of this process. The dynamic cooling necessary for the production of rain is, in this case, the resultant of the two forces termed as above convective and cyclonic; and it is not at all times possible to say how the rain associated with such systems should be described. A similar condition of things occurs with some of the smaller cyclones; but whenever there is a marked horizontal component in the circulation of the wind, the rain which falls is properly termed cyclonic. Now, the enormous quantities of moisture condensed by some of these cyclones amounts, as already indicated, to many millions of gallons, and it follows that equally great quantities of latent heat are set free. This latent heat it is which keeps the cyclone going. Supposing, for instance, a cubic mile of air is at a temperature of 72°, and its dew-point is 61°, it will be necessary before rain can fall that heat be abstracted to an amount that would raise 88,000 tons of water from freezing point to boiling point.

To increase the condensation of rain, further abstractions of heat would be required, and supposing the temperature to be reduced another 10°, the result would be an insignificant shower of rain of only ·25in. in depth, or, roughly, 20,000 tons of water. Such a shower as this is of no importance compared with a fall of 3in., but it liberates sufficient heat to raise 100,000 tons of water from freezing-point to boiling-point, and serves to give the convection-currents in the storm new vigour, and sends the rising columns of air to higher and colder regions, where further moisture is squeezed from them by dynamic cooling.

As already mentioned, the currents of air gain an upward movement by impact with mountains and other inequalities on the surface of the earth, and they are thus thrown upwards and cooled by expansion. It has been suggested that rain which is thus produced should be termed orographic, and so common is this action that it will not be necessary to say very much about it. Such range of mountains as the Andes are very active in producing orographic rain, and it is well-known that winds which strike on one side of this range are thrown upwards, and all the moisture condensed out of them, so that they descend into the valleys on the opposite side of the range as cold, dry, devastating winds. In cases where the sides of the mountains are covered with foliage, there is doubtless considerable rain to be set down to the account of the reduction in temperature, which occurs when the moist warm current of air strikes them, and another factor is accordingly introduced into the problem. Broadly speaking, however, the three chief causes which give an upward component to the winds and so produce rain may be termed convective, cyclonic, and orographic.

A consideration of the many instances in which these three causes may be observed at work throws a little light on the question as to whether cultivation of the land and deforesting has had any effect in diminishing rainfall. Now when once rain has fallen on the ground it either percolates underground or is evaporated to the atmosphere, and it is upon the supplies of moisture gained by this latter process that the future rainfall depends. Cultivation of the ground may increase percolation and decrease evaporation, as is often the case when stiff clay soil is broken up, and if the rainfall of such a locality is produced by the convective methods referred to above, it is possible the local rainfall may be diminished. Further the sides of mountains are warmer when bare than when covered with trees, because absorption of sun heat is greater, and the removal of trees may have an effect on the rain condensed from the currents of air which flow against them. In any case the modification of the amount of rainfall is small, and, as a rule, too much weight is attached to the supposed effects of deforesting. It has been suggested that where the orographic conditions have been thus modified it sometimes happens that the result is to keep rain in a certain river basin that would otherwise have been carried to a distant locality. Moreover, cyclones move in the direction where moisture is most plentiful, and here again it is possible that cultivation of the soil may, by affecting evaporation, diminish or increase the amount of moisture in the air, and the usual course of local cyclonic disturbances may be altered, and in this way some change in cyclonic rain may occur. So many different things, however, cause the amount of rain to vary from year to year, that caution is required in ascribing any suspected change to any one cause.

MILLWRIGHT'S WORK.—XXIII.

At various times millwrights have to take dimensions of worn or broken wheels, and make new ones to gear with existing ones in position. There are a good many points of importance to be attended to in such work, as the following illustrations will indicate. The millwright has to take dimensions, draw out the new wheel, make, or superintend the necessary pattern work, and often to follow it through the foundry. Sometimes broken or worn wheels are brought into the shop; sometimes he has to go and take dimensions of wheels partly or entirely fractured, or of worn wheels still at work, or to take dimensions for entirely new wheels required to effect changes in direction of motion, or in rates of revolution. It is seldom safe to attempt to work from dimensions supplied by people who are not engineers. Often the diameter is given, and number of cogs, but without anything to indicate whether the diameter is at pitch circle, or outside the points of the teeth. Particulars are seldom given of dimensions and shapes of teeth, or of depth of boss, or minor details. So that it is generally safer to send a trustworthy man to take particulars of wheels that cannot be brought to the works.

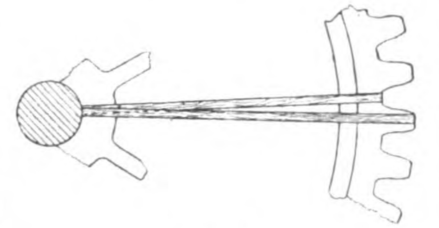

FIG. 145.

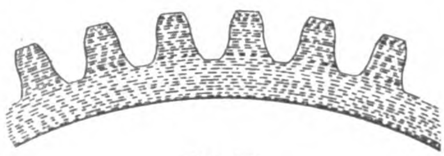

FIG. 146.

Since one doesn't always know exactly what has to be measured, it is generally best to take a plumb-bob or a plumb-rule, a lath or two, a bradawl, screwdriver, and half a dozen screws, a rule, and calipers. With these, any particulars can be taken of spurs or bevels.

If dimensions have to be taken of a spur-wheel in place, and a replace wheel made without any further reference to the worn one, no forethought should be lacking. A man looks very foolish when he comes back to shop, and finds that he has forgotton some particulars without which the wheel cannot be made. There are the major dimensions to be attended to first. Count the teeth, and count twice, chalking the one you start from. Take the diameters to the points of the teeth, and also to their roots. If the shaft is small these may be measured right across on a strip. If the shaft is of moderate or large diameter this cannot be done. Then measure, still with the strip from the shaft to the teeth points, and roots, Fig. 145. One end of the strip will be set against the shaft, and the radius of the latter added on to get the correct radius of the wheel. Or, hang two plumb-lines suspended by nuts, or anything heavy to hand, from the diameter of the wheel at the tooth-points, and measure and mark off the distance between them on the strip.

The shapes of the teeth from which to make the new wheel, or from which to get those of the new wheel in which the old one will have to gear, will be taken by means of a rubbing. That is, a sheet of white paper is taken, Fig. 146, long enough to cover about half-a-dozen teeth, and being laid against one face of the wheel, the fingers are rubbed hard against the paper, over the ends, and round the edges of the teeth. This leaves a good impression of the teeth forms on the paper, of which Fig. 146 gives an imitation. If a sharp outline cannot be obtained thus, in consequence of the tooth faces being very bad, then a wooden templet is fitted between a few teeth, Fig. 147. In either case, having the tooth forms, they are drawn out upon a board on returning to the shop, and the pitch circle and the tooth curves located therefrom.

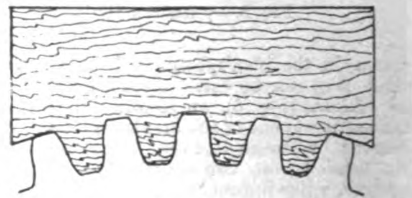

FIG. 147.

Measurements must now be taken of the boss and bore, the arms, and any other particulars needed. The shaft may be measured with calipers for the core prints, but for the boring of the wheel a gauge must be made, Fig. 148. A gauge should be also made for the keyway. Sketches of the arms must be made, and fully dimensioned. Fig. 148 shows a *facsimile* shop-hand sketch of a wheel, in which all necessary dimensions are inserted, and from which, with the rubbing in Fig. 146, a new wheel is made quite as well as from a highly-finished drawing.

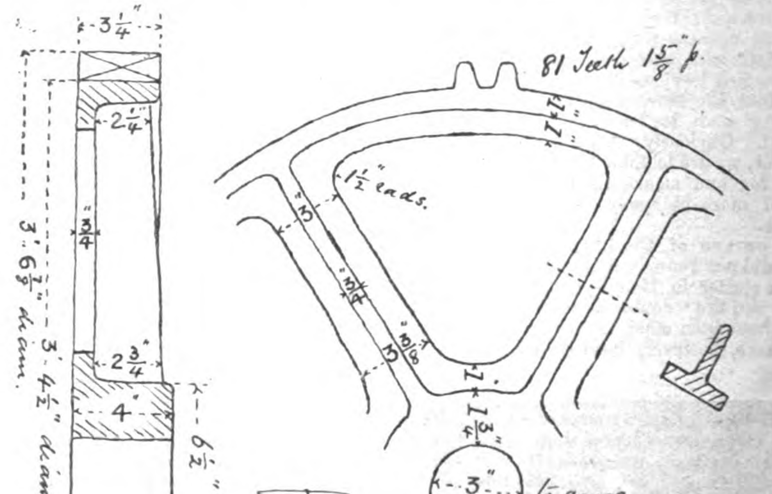

FIG. 148.

An awkward job sometimes is the taking dimensions from a broken wheel, when, as is sometimes the case, it has been utterly smashed

to pieces, and probably some of the pieces are not available. The only course open, then, is to see that all broken parts are brought closely together before attempting to take dimensions, assuming nothing, and checking everything. If, instead of making a new wheel to replace an old one, a new one has to be made to gear with one already existing, then the centres must be taken from the shaft on which the new wheel has to go to the teeth of the wheel with which it has to gear. These are best taken by measurement from the

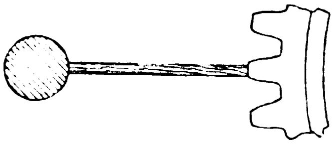

FIG. 149.

outside of the shaft to both root and point of the existing wheel, Fig. 149. Then, having the diameter of the shaft and a rubbing of the teeth of the wheel, the rest can be worked out in the shop.

If the teeth of a wheel are worn very badly, the proper shape for the new one can generally be obtained from the less worn side—one side, as a rule, being merely smoothed by wear, while the other is deeply indented. The thickness at the root is generally intact, while the thickness measured on pitch-line can be obtained from the pitch. If, however, the wheel is to gear with a mortise-wheel, it is well to measure the thickness of the teeth of the latter, for which, if worn, it will be desirable to make the iron teeth a little thicker than the rules give, to avoid backlash.

To get fairly good shapes of the teeth, centres

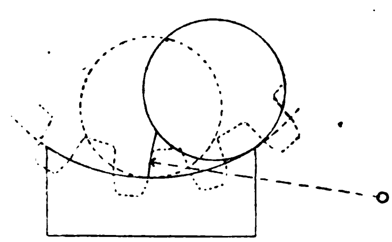

FIG. 150.

will have to be located from which to strike the curves. The teeth will certainly not be all alike, and so an average will have to be struck. It is always safer to give the fullest rounding off to the points which they seem to warrant, in order to avoid possible interference of these when engaging with the roots of the other wheel.

When a wheel has to be made with teeth to gear with an existing wheel, the rubbing, or the wooden templet (Figs. 146, 147), is used to obtain the correct curves from, before those for the new wheel can be determined. If a wooden templet is used, then the tooth-shapes can be scribed off to a drawing-board. If a paper rubbing is used, the tooth-shapes can be pricked through the board, or the paper itself can be glued or pinned on the board; then the centre of the wheel is

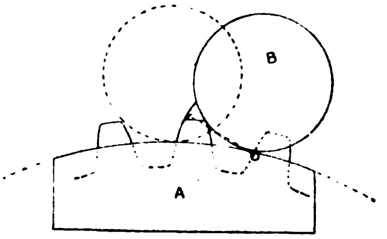

FIG. 151.

obtained, and the position of the pitch-line determined and struck, together with curves for the points and roots. Afterwards the sizes of the generating circles which have been used for points and roots must be discovered. This is done by cutting templets, one of which is shown in Fig. 150 at A to the curve of the pitch circle, and rolling generating circles of different diameters upon them until the one B, Fig. 150, is obtained, which traces the curve. This will often be found to be one having a diameter equal to that of the radius of a small pinion of the same pitch; but in many old wheels, the teeth of which were originally struck without much regard to system, curious results may be expected. When the circle is found, which, when rolled on the pitch diameter, will trace the curve of the tooth—say, above pitch-line, Fig. 150—that will then be used to strike the curves below pitch-line of the wheel to gear with it, Fig. 151.

It will not do to assume that the same circle will strike the curves also of the pinion teeth above pitch-line. It would, provided the original wheel had been struck out on a proper system; but this must be tested by making a sweep for Fig. 150, against which generating circles will have to be rolled to find the curves of the teeth below pitch-line, and then this circle will strike those of the teeth above pitch-line in the new wheel. The rest of the work is merely locating circles, as in Figs. 150-151, from which to strike the curves so determined in a manner which is well understood. J. H.

THE DRIVING OF ELECTRIC GENERATORS.

EVER since the introduction of the dynamo-electric generator into commercial service the question of the best method of driving it has been a subject of discussion, and at the present time the subject of the power portion of an electric plant really constitutes the most important section of the work.

The question of the choice of motive power, and the best methods of application, form the subject of a paper by Herr Robert Friese, published in the *Zeitschrift des Vereines deutscher Ingenieure*, and presented before the recent convention of that society at Nürnberg.

After referring briefly to the electrical magnitudes of voltage and ampèrage, as related to the mechanical elements of force and distance, and showing how the equations giving the relations of electricity generated to power required may be derived, Herr Friese proceeds to consider the various methods of connecting the generator to the source of motive power by which it is driven. The development of the direct-connected generating set is discussed, and the important influence which this development has exerted upon steam-engine design is shown to have been for the improvement of both generator and engine. With the earlier dynamos the high rotative speed required demanded quick-running engines, and although some very excellent machines of this type have been made, such as the Westinghouse engine in America, and the Willans in England, yet it is generally conceded that the best economy is attained by larger engines operating at moderate rotative speeds. The improvements made in large alternating and polyphase generators render it possible to use such engines in direct connection with the generators, and this type, with vertical engines and large armatures built directly upon the engine-shafts, is the prevailing form now used in large electrical stations where steam is the motive power.

The question of speed regulation has naturally been given much consideration in connection with the subject of driving electric generators, and Herr Friese has some interesting remarks to offer in that connection. While the centrifugal governor maintains its supremacy, in spite of its inherent defects, the demands of electric service have resulted in various improvements in the matter of speed regulation. The natural auxiliary of a governor is a flywheel, and in one form or another the inertia of a revolving mass is generally relied on to assist in the maintenance of uniform speed. The usual method of expressing irregularity in speed is that of a percentage variation from the normal, it being stated that the speed shall not vary, for example, more than 2 per cent. above or below the standard; but this method does not give a clear idea of the conditions, because it fails to take into account either the duration of the regulating operation or the number of variations from the normal which may occur during that time. The fluctuations of electric lamps, however, make both the extent and duration of speed variations visible. Herr Friese calls attention to the difference in sensitiveness of people in different walks of life to variations in brilliancy of electric lamps, and shows that fluctuations almost unbearable to persons of culture were hardly perceptible to the peasant labourer, so that the personal equation must be considered in this connection, as well as the service to which the light is to be put. As a matter of fact, the degree of variation in speed is not a constant factor, as some treatments consider it, but is a resultant of varying influences in every portion of the combined machines. All that can be expected is the restriction of the variations within certain predetermined limits, and this should be effected not only by regulating the impelling power after the variations have occurred, but by so combining the parts that the variations may neutralise each other as nearly as possible, and at as early a point as possible after their inception.

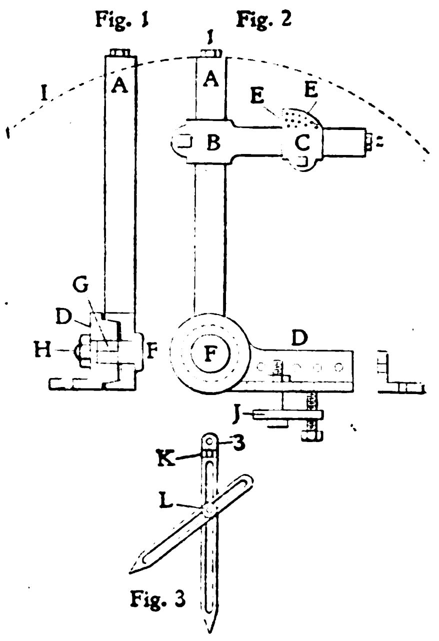
As an example of what can be done in this direction, the subject of the connection of electric generators in parallel is discussed, and the equalising effects of two generators is illustrated by comparison with that of two engines geared in parallel with a certain degree of elasticity in the connections. The use of accumulator batteries for the purpose of equalising variations in the load is also considered, and the analogy of such batteries to flywheels is clearly shown.

The probable use of gas-engines for the driving of electric generators is considered, and although the single-cylinder four-cycle engine is considered unfit for this service, Herr Friese maintains that with two or more cylinders, and with proper arrangements for the equalisation of the load, there is no reason why the internal combustion motor, with its superior economy, may not come into general use as a motor for dynamo-electric machines.—*Engineering Magazine.*

A NEW "OLD MAN."

THE following description of the workshop appliance known as an "old man" may be useful, or at least suggestive, to many readers. It is by Mr. W. de Sanno, of Kern City, California, and is published in *Locomotive Engineering*, N.Y.

As far back, he says, as he can remember (and it

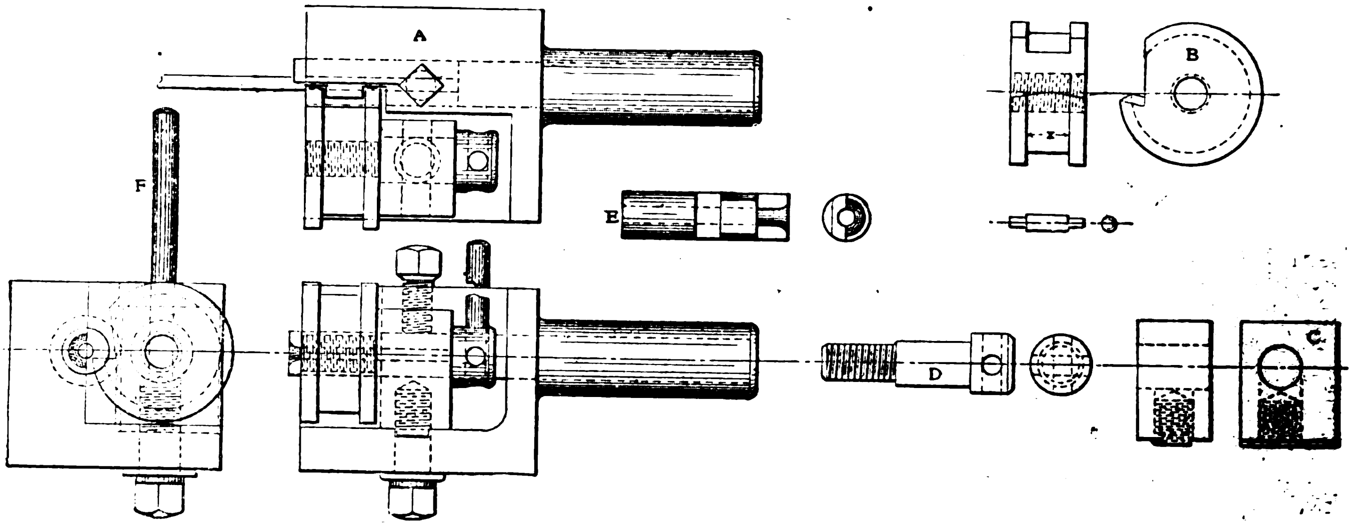


is a long way back) the tool known as "old man," used in ratchet drilling, was of the same shape as it is to-day. Having been put to my wits' end many a time for something to support my ratchet, the appliances in general use not being suitable for the job, an "old man" of the design shown suggested itself to me. A A, Figs. 1 and 2, is the post, B the arm, and C a hardened piece that will pinch on post or arm, as the case requires. The spots shown on the side of C are permanent centres for the feed-screw of the ratchet. The curved and straight faces E E also have the permanent centres. The idea of the piece C is that there is no position for the ratchet that one of these centres cannot be used for, thereby obviating the necessity of putting centres in the post or arm.

You will notice the lower end of the post A has a boss, bored out taper. The angle foot D also has a boss, fitting into boss on post A, making a male and female fit. The taper is of such a degree as will make a tight fit when drawn together by the bolt F; and the fit is not supposed to move when any reasonable pressure is exerted by the ratchet. The hole through the boss on the angle-foot D is square, and the end of the bolt F made square to fit. This prevents the post moving and slackening the nut H. So far as the angle-foot D is concerned, the post A has a full sweep of a complete circle.

J is a clamp to be used when required. Fig. 3 shows an adjustable brace to be used when required. The brace is secured to the post or arm by the bolts 1 and 2 passing through the hole 3. At K is a hinge joint to allow the brace to adjust itself. At L is a pinching bolt to hold cross-brace in position.

I don't know why good malleable iron would not do for this tool by coring the post and arm and doing just as little machine work as possible to save the outside skin. Perhaps steel castings would be better. It is not patented.



BOX TOOL FOR PIVOTS.*

THE accompanying drawings illustrate a box tool for making clock pivots, corner posts, or anything of that class in which accuracy between shoulders is required.

A is the body of the tool, with shank to fit turret; B is a circular tool recessed at x to a width corresponding to distance required between shoulders. B is pivoted in block C by bolt D, which has left-hand thread and holes at right angles in head to receive pin F. Block C has cross adjustment to regulate diameter of pinion ends. E is a bushing to support stock while being cut, and is cut away as shown, to clear B.

To operate, the tool is brought forward to the stop with the right hand, as is usual in screw machine work, and cutting-edge of tool B is forced against the stock by pressure of left hand on pin F, which is continued until the cutter swings by. It is then turned back to clear the stock, and withdrawn from the work, which is then ready for cutting-off tool.

The diameter of the pinion ends will vary if the stock is not of a uniform diameter, but this may be avoided by selecting the stock with a micrometer. The distance between shoulders cannot vary, and removing the tool and grinding it does not necessitate readjusting. The stock, running in the bushing, while being cut, prevents burrs forming on the corner of the shoulders, and the body and ends must be concentric, which is important on some work.

With this method, if the stock is not round the pinion ends will be out of round also, but as cold-drawn stocks run within one-half a thousandth, the error will be within reasonable limits.

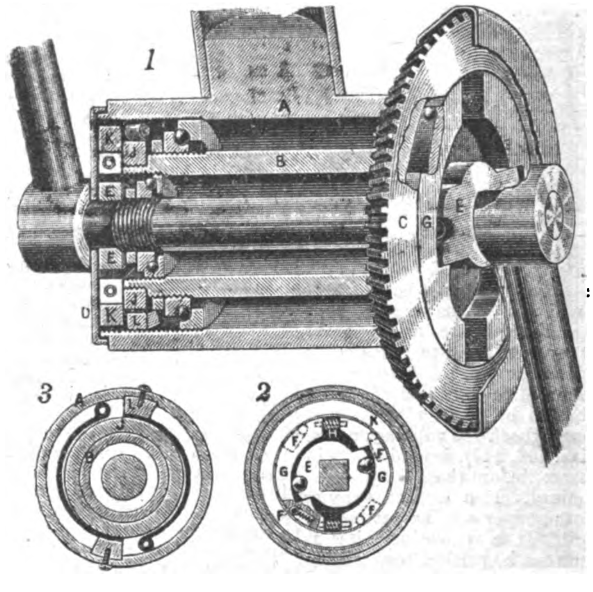
* By A. J. STRONG, in *American Machinist*.

BACK-PEDALLING BRAKE FOR CYCLES.

THE following description of a back-pedalling brake, which, according to the *Scientific American*, presents many novel features in its construction, has been invented by Edgar S. Stem and Arthur O. Dunlap, of Alderson, Penn. Fig. 1 is a general view of the device; Figs. 2 and 3 are cross-sections.

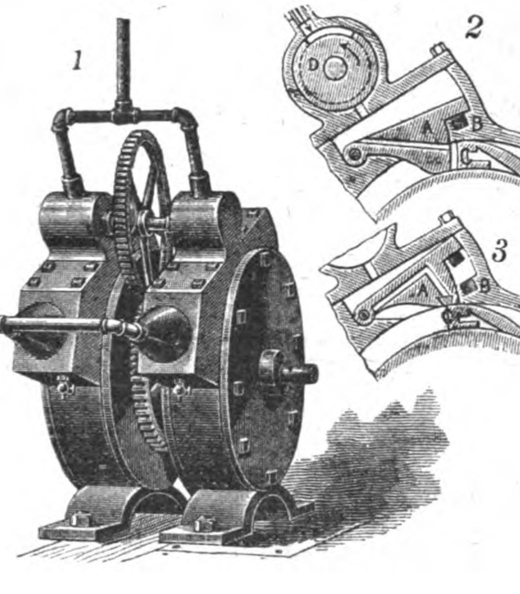
The braking mechanism is applicable both to chain and chainless wheels, and is contained in the crank-hanger. On suitable bearings, a sleeve, B, is carried, forming the trunnion for the driving-gear wheel C. The pedal-shaft turns on bearings within the shaft B. At one end the crank-hanger is provided with a case for the gear wheel; at the other end with a cap, D. Near the cap end of the pedal shaft a cross-arm, E, Fig. 2, is fastened, forming a clutch member, having eccentric edges terminating in shoulders, adapted to engage corresponding shoulders on shoes, G, likewise provided with eccentric edges. Recesses in the cross-arms E contain balls for rollers designed to engage the edges of the shoes G. A ring, K, is loosely fitted within the crank-hanger, and a cam encircles the clutch member E, and is held in place by the cap D. When the shaft forces the shoulders of the cross-arm E into engagement with the shoulders of the shoes G, the shoes are turned loosely within the ring K and around with the shaft and clutch member E. But when the shaft turns in the opposite direction, the rollers or balls are forced against the eccentric inner edges of the shoes, thus locking the shoes and ring together. Rigidly secured to the left end of the sleeve B is a collar, J, Fig. 3, against which act two brake-straps, each fastened at one end of the crank-hanger by a dovetailed connection, L. The other ends of the straps are connected with the ring K by pins. When the ring is idle, the brake-straps are loose; but when the ring is locked with the shoes G, and therefore turned with the shaft, the straps will be drawn tightly against the collar J.

At the gear end of the crank-hanger a somewhat similar clutch mechanism is provided. Here we also have a shouldered cross-arm, E, the balls of which are caused to impinge against brake shoes, G, held movably together as in the first case. There is, however, no loose ring. When the shoulders of the clutch E and of the shoes G are in engagement with each other, the clutch member, E, the shoes, and the shaft turn together. When the clutch member E is turned in the opposite direction, the rollers on the clutch member bind against the eccentric edges of the shoes, and lock the gear and shoes together, so that the gear is caused to turn with the shaft. When the shaft is driven forwardly by the pedals, the clutch member E on the gear end will be caused to turn with the shaft, in the manner just described. When it is desired to coast, the pedals are held stationary, and the parts are free to run. In order to stop the machine, back pressure is applied to the pedals, so that the clutch E on the left end will throw the shoes G out against the ring K, thereby causing the ring to turn, contracting the brake-straps against the collar J, and stopping the motion of the sleeve B, and therefore of the gear C.



MUSICAL PITCH.

AT a meeting of the Musicians' Conference last week, the chairman, Mr. W. H. Cummings, principal of the Guildhall School of Music, delivered an address on "Musical Pitch," and in the course of that observed that the past history of musical pitch was somewhat remarkab'e. There was a prevalent idea that centuries since the standard pitch was very low, and that it had been steadily rising until it had strained voices and strings almost to breaking point. This was a fallacy that could be shown by reference to a few well-established facts. Pitch had been lowered to suit modern necessity. In Handel's time there were two pitches—Church and Concert—and the former was a whole tone higher than the latter. Those who were familiar with Purcell's music would readily recognise the evidence it gave of two distinct pitches. Comparisons of Church and chamber music of the 16th and 17th centuries afforded similar conclusions. On the Continent there were formerly also two pitches. But now there was practically one pitch there, which approximated very closely to that known as the "diapason normal." As a result of the action taken by himself and others, the pitch known as the Philharmonic Concert Pitch was adopted and generally warmly approved. By the universal adoption of this pitch many works which were distressful from the strain put on voices would become comparatively easy. Moreover, singers who travelled to foreign countries would not be confused by differences of pitch, and the same might be said of violin players. It would also facilitate the time when children would be able to sing without the Sol-fa figures or any other crutch for musical cripples. Speaking, as he did, to practical musicians, he need not say more of the great advantage which would accrue from one universal pitch, and he was sure they would be glad to witness its adoption in the future. One of the difficulties which presented itself was the attitude of some of the British pianoforte manufacturers, who appeared to think they were the arbitrators in a matter which, he took it, scarcely came within their prerogative. Surely, if they, as performers and practical musicians, were of opinion that a lower standard of pitch was desirable, that ought to suffice and settle the question. If British makers would not supply the needs, then musicians would be driven to obtain the instruments they required from foreign sources.—Prof. Prout said he was a most hearty supporter of the proposed lower pitch.—Mr. T. Westlake Morgan (Bangor) had found, during the past three years, since the change in the pitch of the organ at the cathedral, that the choir singing had lost the element of brilliancy which it before possessed. He did not say the lowering of the pitch had been a mistake. Time would show, but it was the opinion of people attending the church that the singing was now not so good.



Sir Frederick Bridge observed that the alteration of pitch would, in some instances, involve much cost. That was one of the difficulties. To alter the pitch of the great organ at the Albert Hall would cost something tremendous. The pitch of that organ was the highest he had ever met with. The change to low pitch had been attended with some curious experiences. In the case of Birmingham it had, at first, most curious results. An oratorio performance could not be given in the low pitch, for the pitch of the instruments was not suitable, so poor unfortunate Mr. Perkins, the organist, had to transpose the whole by half a note to suit the instruments. The result was that the performance was given in a key half a note higher than before. It was the same all over the country, and instruments had to be obtained to suit the lower pitch. It seemed to him, however, that there was such a body of expert opinion in favour of lowering the pitch that by doing so they could not go far wrong. Mr. Frederick H. Cowen said that at first he was rather against the lowering of the pitch. He had a sort of idea that it would interfere with the brilliancy of a performance, but he had been fast coming round during the last two or three years to the idea that it would be better all round if they had the low pitch adopted in this country. He hoped some resolution would be taken, and some movement made by which the pitch could be lowered universally throughout the whole of the country, and the sooner they did that the better.

Upon the motion of Sir F. Bridge, seconded by Mr. Gardner (London), it was unanimously resolved "That it be a recommendation to the general council that they consider the question and take such action as they deem desirable."

THE BIGGEST FAST STEAMER IN THE WORLD.

WHAT the German claims to be the largest fast steamer in the world, the *Deutschland*, will shortly be launched by the Emperor from the Vulcan Yard at Stettin. The *Deutschland* has been constructed to the order of the Hamburg-American line, and will run between Hamburg and New York. She has a length of 208·5 mètres, a breadth of 20·42, and a depth of 13·41. Her displacement fully laden is 23,200 tons and her register tonnage is 16,200. The ship exceeds the *Kaiser Wilhelm der Grosse*, built by the same firm in 1897, by 11 mètres in length, and by 0·3 mètres in breadth and depth. Her displacement is about 2,500 tons and her register tonnage about 2,000 tons greater. Schooner rigged, the *Deutschland* is built in numerous water-tight compartments, and her pumps will enable 4,000 tons of water an hour to be taken out of her, should the necessity arise. She is of steel, will accommodate 467 first-class passengers, 300 second-class, and 290 third-class, while her crew will number 525. She will be lighted electrically by 2,000 lamps, and will carry 20 boats. Her indicated horse-power is 33,000. The *Deutschland*, which would have been launched on the 3rd intant but for the ice, will certainly be one of the monarchs of the ocean.

THE average daily advance of the Simplon Tunnel is about 30ft.; but the contractors will have to average 42ft. to 46ft. per day, in order to meet their engagements. About 2,600 men are at work, and twelve drills. The calculated length between the two heads of the tunnel is 12¼ miles.

JAMES'S ROTARY ENGINE.

AN ingenious rotary engine, in which the steam is used expansively, has been patented by William F. James, of Phœnix, Arizona Territory, says the *Scientific American*. Fig. 1 of the accompanying illustrations is a perspective view of a compound engine; Fig. 2 is a cross-section, showing the cut-off valve and abutment; Fig. 3 is a detail section, showing the valve in a different position. The cylinder casing is provided with two recesses, one of which serves as an exhaust-chest and the other of which receives the abutment. The piston, upon which the abutment bears, consists of a block, C, secured to the outer surface of the piston disc, so as partly to close the steam space. Secured to the block C is an inclined plate resting on the piston disc. By placing packing-plates between the inclined plate and the block C, the depth of the piston in a radial direction may be regulated. The abutment A is hinged to the outer casing so as to swing up or down, in obedience to the action of the rotating piston. The abutment is provided with an extension engaging the wall of the recess; the swinging movement of the abutment is therefore limited. By this means the disc is relieved of the pressure of the abutment without destroying the steam-tight contact. A steam-port extends through the abutment, and opens at the swinging end, so as barely to clear the wall of the steam-chamber. When the abutment is in the position shown in Fig. 2, steam is admitted through ports in the abutment recess. To avoid the jar due to the seating of the abutment upon the disc, a dash-pot is employed, entering a hole, B, in the casing. In order to work the steam expansively, a rotary cut-off valve is employed, which is geared with the piston-shaft. The gears are of such diameter that the valve and shaft rotate synchronously. By providing the engine with two or more cylinders, the pistons are placed opposite each other, so that there are no dead centres.

PICRO-CARMINE AND ALUM-CARMINE AS COUNTER STAINS.*

THE excellence of picro-carmine was first noticed in staining developing bone which had been decalcified. Picro-fuchsin was being regularly used as a counter stain with hematoxylin. Merely for the experiment picro-carmine was used on one section and left nearly two hours. Much to our surprise and, pleasure we found that, instead of our section being ruined, we had secured an excellent differentiation. This was not the first attempt with picro-carmine, but always before the time had been short, from two to fifteen minutes. The advantage of the stain over picro-fuchsin is noticeable in the superiority of differentiation secured.

The embryonal cartilage cells are better marked by the hematoxylin and picro-carmine, for the alkaline picro-carmine does not fade the hematoxylin as does the acid picro-fuchsin. It is particularly in the zone of calcifying cartilage that this superior differentiation is noticed. The vertically-arranged rows of cartilage cells have lost their horizontal septa, but the vertical septa are pronounced and project into the primary narrow cavity as irregular trabeculæ of calcified cartilage. The osteoblasts have enveloped these trabeculæ with a covering of true bone, and at the same time the cartilaginous trabeculæ within are being absorbed, and true bone substituted.

This true bone, with the picro-carmine, has taken a red which is brilliant in comparison with picro-fuchsin; and the gradually diminishing and disappearing cartilage which, with picro-fuchsin, has taken a stain not distinguishable from that of the cells of the true bone is, with picro-carmine, beautifully differentiated by a clear pronounced blue, showing the alkalinity of the picro-carmine. This tendency on the part of picro-carmine to bring out the hematoxylin as a blue, while the acid picro-fuchsin fades it, is very noticeable in the tonsil of dog which was next submitted. In the mucous cells near this gland the nuclei, removed as far as possible from the lumen, are brought out with unequalled clearness. The structure of the blood-vessels is also brought out with great distinctness, and the differentiation throughout is very marked.

Quite as striking a contrast between picro-carmine and picro-fuchsin is noticed in a section of the pyloric stomach of a kitten. The stain with picro-carmine is not only more differential, but the unstriped muscle of the stomach and blood-vessels is brought out much better by the picro-carmine. During the summer picro-carmine was tried with good results on sections of the Fallopian tube of a mare. It has been used with greatest success on tissues which present a mucous surface, and while these successes have been noted, an equal number of failures were encountered, so no claim is made for picro-carmine as a "pan" stain. It seems particularly unsuited for tissues that stain with difficulty. Ranvier's picro-carmine was used in most of these experiments, but Bizzozero's was used with equal success. Mayer's recent formula was used in the histological laboratory at Cornell last year, with results quite as good as those from Ranvier's.

In the summary, then, we find picro-carmine, in the cases noted, gives, with hematoxylin, a more differential stain than picro-fuchsin, and shows the characteristic alkaline reaction with hematoxylin, bringing out the hematoxylin as a beautiful sharp blue, while the acid picro-fuchsin tends to fade it. Two hours is, in general, the best time for picro-carmine. There is no danger of overstaining. Stohr, in his textbook of "Histology," directs that developing bone be stained with hematoxylin and then with picro-carmine.

Alum-Carmine.

During the summer it was my privilege to prepare some slides of liver of guinea-pig to show Anthrax bacilli. I attempted to get a contrast stain, and finally succeeded with alum-carmine. I had tried picro-carmine without success, and had never been able to secure a good stain with picro-carmine on liver. One hour and fifty minutes with alum-carmine gave the best results. The crystal-violet with which the bacilli were stained, and which is washed out much or entirely by the alcohols and clearer, must be sufficiently intense to permit of thorough dehydration and clearing and yet leave a distinct stain. One minute and a half will suffice if care is taken not to leave longer than is necessary in alcohol. By this stain the nuclei and the cell-body are clearly differentiated, and the alum-carmine forms a very good contrast stain with the crystal-violet. The simplicity of the method commends it. With methylene blue a still greater constrast may be secured.

* By B. D. MYERS, in the *American Monthly Microscopical Journal*.

CARBON LANTERN SLIDES.

IT is generally conceded that the acme of perfection in slide-making is reached either by the Woodburytype or carbon processes; the former is, as a rule, quite beyond the amateur, and the latter is not very much used, as the preparation of a slide by means of the gelatine lantern plate is so simple. The beauty of the carbon slide lies, as a rule, in the exquisite transparency of the shadows and the perfect rendering of all the tones in the negative, and the general absence of anything like grain, as the pigment in special transparency tissue looks more like a stain than a solid.

For absence of grain there is no doubt that the gelatino-chloride printing-out plate ranks next to them, and then the gelatino-chloride developing plate. It is possible, however, to obtain slides in almost any colour by what is certainly a carbon process, and a modification which has the advantage of requiring no tissue, but in which the ordinary gelatino-chloride printing-out paper can be used.

It is immaterial whether the paper has become yellow through age or whether it is a spoilt print, though in the latter case the printing is a little more difficult.

Allow the paper to darken to a deep rich colour by exposure to daylight, but in no case must it be allowed to bronze; it should then be immersed for two minutes in a 5 per cent. solution of common salt, then a 4 per cent. solution of bichromate of potash and dry it, preferably by squeegeeing it to a piece of waxed plate glass and allow it to dry in the dark. When thoroughly dry, it can be exposed under the negative, allowed to soak in water till limp, and then squeegeed to a lantern plate from which the silver image has been removed by means

of potassium cyanide well washed, and then treated with a 10 per cent. solution of formalin and rinsed. The exposed paper may be squeegeed to a plain piece of glass without any gelatine, but it requires extremely careful handling.

When squeegeed down, it should be left for at least half an hour and then developed in warm water exactly as an ordinary carbon print, only that the paper should not be pulled off, but merely allowed to float off.

When the image is quite developed, it may be dipped into alum solution or weak formalin, washed, and then toned with any gold bath or platinum, or intensified by any of the ordinary methods as used for negatives. Exquisite results are obtained by merely immersing in a 10 per cent. solution of silver nitrate, blotting off superfluous moisture, exposing thoroughly to daylight, and then toning in a combined bath.—A. D. PRETZL, in *British Journal of Photography*.

USEFUL AND SCIENTIFIC NOTES.

THE native countries of the tallest and shortest people of Europe, the Norwegians and the Lapa, adjoin each other.

FOR several years attempts have been made at Omaha and Los Angeles to hatch the egg of the ostrich artificially, but so far these attempts have been unsuccessful, the difficulty being the application of moisture. Now, however, an ostrich farm in Florida can boast of the first incubator-hatched ostrich in the United States. The incubator required 41 days of careful watching; the thermometer was kept at 110°, and the moisture was applied at intervals.

On the Wing at 8,000ft. Altitude.—The Rev. J. M. Bacon, in *Knowledge* for January, describes his balloon ascent in November last in quest of the Leonids, and mentions, incidentally, some facts of peculiar interest. He says:—"The trivial incident of our having suddenly found a big blue fly buzzing noisily about us, when hanging at a height of 8,000ft., would have passed without serious notice but for certain correspondence which has since arisen. Mr. F. T. Wethered, of the Alpine Club, writes to say that he has seen a butterfly scudding across the summit of the Grandes Jorasses at a height of 13,799ft., and sees no reason why the fly should not have been on the wing, and not taken up in the car, as we had supposed. M. C. Flammarion tells of white butterflies fluttering round his balloon at 3,280ft., though in the same voyage he remarks on the silence of bird and insect life at sunrise. My own experience has always been that winged creatures of every kind have been left behind long before the first thousand feet were reached. The height at which the swift is flying is surmounted with the first leap into space, and even when sailing at the lowest levels compatible with safety the skylark is neither seen nor heard. Very possibly, however, all creatures of the air take alarm at a balloon, and naturally give it a wide berth."

The Danger of Flash-Lights.—Notwithstanding the number of serious accidents that have been chronicled, and the cautions given as to the dangerous character of most of the flashlight compositions, mishaps are continually occurring. We read of one that recently happened in a studio at St. Louis, which may serve as a warning to those who compound their own flashlight powders here. Briefly, the facts are these:—An operator was using the blade of a knife to mix a quantity of Blitz powder and magnesium together, when the compound ignited, with the result that the man was terribly burnt about the face, hands, and arms, and had to be removed on an ambulance to the City Infirmary, where his condition was found to be serious. It was also stated that some of the white-hot flame had been inhaled by him, which, of course, added greatly to the gravity of the case. We have on several previous occasions warned those who make flashlight powder, containing chlorate of potash and the like, as to the way that the compounds should be mixed. They should be dried and pulverised separately, then mixed in small quantities at a time, as required for use, on a sheet of paper, using a strip of stout paper or thin cardboard for the purpose. Had this method been adopted in the St. Louis studio, the accident would not have happened. There the operator used the blade of a knife for the purpose, probably because it was more convenient. Here is one more caution we would give:—When mixing the ingredients in ever such small quantities, do it at arm's length, because then, if the mixture does ignite, the operator's face will not be injured by the flame, as in the case just cited, for most of these compounds are liable at times to "play tricks," and go off when least expected. Our object in specially calling attention to this accident is to once more impress the necessity of extreme caution upon those of our readers who may not know the dangerous nature of the material they are dealing with when they compound their own flashlight powders.—*British Journal of Photography*.

SCIENTIFIC NEWS.

IT is announced that the Paris Observatory will adopt the plan of time-reckoning from midnight to midnight, which has been adopted by the *Nautical Almanac* for many years.

The editors of the *Observatory* magazine ask us to state that, owing to the change in the system of time-reckoning in the *Annuaire* of the Bureau des Longitudes, the variable star Ephemerides in the *Companion* for 1900 are given in Greenwich civil time, the day being considered as beginning at midnight.

An ephemeris of the minor planet Eros is given by Signor Millosevich, of Rome, in *Astronomische Nachrichten* 3609. The period of the planet is 643·14d.

The prizes offered by the Paris Academy of Sciences for 1900 are—the Lalande (540 francs) for the most interesting observations or for work most useful to the progress of astronomy; the Damoiseau prize (1,500fr.) for a memoir on the theory of one of the periodic comets of which several returns have been observed; the Valz prize, for the most interesting astronomical observation made during the year; the Janssen prize (gold medal) for the most important discovery in physical astronomy; and an "anonymous" prize of 1,500fr. for the encouragement of calculators of minor planets, especially those planets discovered from the Nice observatory.

Holmes's comet is calculated to have a position on Jan. 20, G.M.T., of R.A. 2h. 23m. 17s., N. Dec. 40° 17' 38·4", but it is probably so faint that it can be observed only with the most powerful instruments. Even with the Lick telescope it appears to have been only glimpsed in August and September last.

In *Knowledge* for this month Mr. E. Walter Maunder, F.R.A.S., commences a series of articles on "Astronomy without a Telescope," and Mr. A. Fowler, F.R.A.S., has an article on "The Constituents of the Sun," with illustrations of spectrum analysis.

Prof. A. S. Herschel, writing from Slough on Jan. 3, says there was an unusually fine shower of the Quadrantid shooting-stars through nearly all last night, which the clear sky here gave me a very favourable opportunity to observe continuously, from 11h. p.m. until 4½h. a.m. this morning. The meteors fell all the while at a rate of about twenty-five per hour, and consisted mainly of first and second magnitude shooting-stars. But at 2h. 58m. one must have been of three or four times the brightness of the planet Venus, for it cast a glare on my notebook which made me look up overhead, and enabled me to see the long and broad bright tapered light-streak there, which remained, on the path which it had traversed, persistently visible for about ten seconds. Another meteor of the shower at 4h. 17m. was also quite as bright as Venus, and left a sensibly curved long wide yellow streak of light for six seconds along its track. About three minutes after its disappearance, two second magnitude Quadrantids ran a race side by side across the head stars of the Great Bear, about 5° apart, keeping nearly abreast of each other for some 20°: while at 2h. 22m. a meteor as bright as Vega Lyræ disappeared, after a course of about 20°, for about 5° or 6°, and then reappeared almost immediately, and described a further course of about 12°; unless the latter part of the visible bright course was perhaps also a second independent meteor. Eighty meteor-paths were mapped and fifty more were counted, making 130 Quadrantid and other meteors seen in a five-and-a-half hours' watch. Of this number about four-fifths appear to have been Quadrantids, with a rather scattered region of radiation round the usual centre of the shower in Quadrans Muralis. But the mapped paths have not yet all been projected to determine their radiant focus, if it was a well-defined one, with exactness. Only one of the brightest, besides the two already-mentioned large ones, left a faint enduring light streak, and the heads were also seldom tailed with sparks, and presented only long-flighted, bright yellow, starlike points of light. The exact date and hour of this shower's annual return has not been well observed for many years, owing generally to cloudiness of the nights and mornings of Jan. 1 and 2; but also owing to scantiness of its displays, which in any clear hours of those nights have not for a long time been very brightly recorded. The exceptional richness of the shower last night in brightness and numbers of its meteors at least marks its time of greatest intensity this year with unusual certainty, if it does not perhaps also indicate that the shower's return this year was one of the earth's encounters with a quite exceptionally dense portion of this somewhat overlooked and but little watched for and investigated meteor-cluster.

The death is announced of Mr. Henry Tracey Coxwell, who was born at Wouldham, near Rochester, in 1819, and was well known (by name at least) to balloonists all over the world. In early life he took much interest in the subject of balloons, and in 1848 commenced his work as a professional, making several ascents from the Continent, and in 1859 from the Crystal Palace. In later years, when the British Association took up the observation of meteorological conditions at high altitudes, Mr. Coxwell, with Mr. Glaisher, F.R.S., as the scientific expert, made several ascents, and the memorable one of Sept. 5, 1862, when a height of seven miles above the earth was reached. Mr. Coxwell urged upon the authorities the value of balloons in war long before they were adopted.

Mr. Richard Boyse Osborne, who was born in Wexford in 1815, migrating to the United States in early years, died recently near Philadelphia. He became one of the most sucessful civil engineers in America, and was at one time the chief engineer of the Philadelphia and Reading Railroad. He returned to Ireland, and took charge of the construction of the Waterford and Limerick line, and then, going back to America, he did much valuable engineering work, and planned and laid out Atlantic City. Mr. Osborne was the originator of the well-known "Lyons' Tables," which are extensively used by civil engineers.

Prof. Elliott Coues, the eminent American naturalist, died at Baltimore, Maryland, on Christmas Day. He was born in 1842, and entered the medical department of the United States Army. He saw many years' service in various parts of the country until his retirement by resignation in 1881. Wherever he went the scientific tendency inherited from his father was stronger than the purely professional one. His "Key to North American Birds" (1872) and his "Field Ornithology" (1874) had already given him recognition, so that he was made secretary and naturalist to the United States Geological and Geographical Survey, under the direction of the late Dr. F. V. Hayden. He edited the publications of this bureau from 1876 to 1880, conducted zoological expeditions in the West, and published his "Birds of the North-West," "Fur-Bearing Animals," and "Birds of the Colorado Valley." After his retirement from the army he took the professorship of anatomy in the National Medical College in Washington, and did hard work in it as a lecturer during the succeeding ten years. Dr. Coues was interested in the phenomena of spiritualism, and at one time was a theosophist, and, although he lost interest in this during recent years, he never ceased to maintain the inadequacy of science to deal with the intricate problems of life. In 1884, while visiting England, he became a member of the Psychical Society, and after his return was engaged for several years as one of the experts on the Century Dictionary, with complete charge of the departments of biology, zoology, and comparative anatomy.

M. Emile Weyl, whose death is announced from Paris, was a well-known writer upon naval subjects, who for many years, up to the volume of 1898, contributed the chapter on foreign navies to the "Naval Annual." His acknowledged competence caused great attention to be paid to his writings, and he took a prominent part in creating a wave of popular interest in the French navy. He retired from the French naval service as lieutenant about the year 1884, and was afterwards a frequent contributor of naval articles to French papers. He was made a chevalier of the Legion of Honour after the Crimean campaign, and was advanced later to the rank of officer.

Mr. H. J. Carpenter, formerly at the Royal Observatory, Greenwich, and afterwards assistant at Durham Observatory, died the other day at the age of forty-nine.

At a recent meeting of the Paris Academy of Sciences a memoir was presented by MM. Vaschide and Van Melle on the nature of the

physical conditions of smell. The authors have a new hypothesis. They suggest that, instead of the sense of smell being due to the emission of particles from the substance, the effect is produced by rays of short wave-lengths. In support of their view the old objection to the "emission of particles" theory crops up—that the substances which give off the odours do not appear to lose any weight by the "emission."

The University of Glasgow will, according to the will of Mr. J. B. Thomson, of Kinning Park, Glasgow, receive £10,000, and the Glasgow Technical College £2,000.

It is intended to hold a congrès d'histoire des sciences at Paris in connection with the exhibition. Prof. Tannery is the president of the organising committee, and Dr. Sicard de Planzoles the secretary. The conference will deal with the progress of all branches of science. The secretary's address is Boulevard Raspail 10, Paris.

In the course of his Christmas lectures at the Royal Institution, Prof. C. V. Boys, F.R.S., referred to the behaviour of liquids flowing through tubes of varying cross-section. At first sight it would be expected that the pressure would rise at the narrow places and fall at the wide. But when the experiment was tried, the contrary was seen to be the case. Explaining this, he pointed out that the same amount of liquid was passing at both the narrow and the wide places, and, therefore, the stream must be running more quickly where the pipe was constricted than where it was wide. This implied that its speed was gradually increasing as it got nearer the narrows, which was equivalent to saying that the pressure behind it was greater than the pressure in front. The Venturi water-meter was described as one of the most beautiful inventions made in modern times to overcome an apparently insuperable difficulty. Its construction was based on the principle that if a water main was constricted at a certain point the pressure fell from the wide to the narrow place. From the difference between the pressures at the two points the velocity of the flow could be calculated, and thus, the size of the pipe being known, the amount of water passing could be measured, as was automatically done by this meter.

In another lecture, referring to artificial flight, Prof. Boys mentioned two important aspects of the problem—the art which the aëronaut had to learn of managing his aëroplanes when he was up, so as to keep his balance, and the mechanical question of getting enough power on the machine without making it too heavy. In the former respect, names which stood out were those of Lilienthal and Pilcher, both of whom were killed in their experiments with soaring machines, while in the latter Mr. Maxim was conspicuous as having constructed the lightest reciprocating engine ever made for its power. Prof. Boys showed pictures of the machines both of Pilcher and of Maxim, and gave a brief account of a trial he made with the latter, in company with Lord Kelvin and Lord Rayleigh.

The skill of Prof. C. V. Boys, F.R.S., with soap-bubbles, quartz threads, and sundry other scientific phenomena, is well known, and in his concluding lecture at the Royal Institution delighted his audience. The experiments had reference to what is termed "surface tension" of liquids—that property which makes a drop of water cling for a little time to the nozzle of a tap until at last its growing weight detaches it, instead of falling at once as a stream of sand would do; which makes water cling to the meshes of a fine wire sieve; which produces capillary attraction, and which accounts for the soap-bubble. Prof. Boys did not attempt to explain the way in which the elastic skin on the surface of a liquid produces capillary attraction, or how this elastic property, which is always pulling the liquid back into its original state after it has been disturbed, enters into the life-history of the bubble; but after the beautiful experiments he made there will only be a small proportion of his young hearers who will not want to find out further how it is done. The elastic skin of water and its properties were illustrated by methods which are peculiarly those of Prof. Boys. For instance, a finely-meshed sieve, with meshes previously greased with paraffin, had a piece of paper placed inside it so as to cover the bottom, and water poured in. The paper was then withdrawn, and the water still remained in the sieve, refusing to run out—being, in fact, upheld by the "elastic skin" of water on its surface, which clings to the meshes as if it were a solid. The sieve was shown to be able to float on water, for a similar reason. Another experiment showed water supported in a small test-tube by this same elastic skin, although the tube was turned mouth downwards. Prof. Boys gave a final touch of ingenuity to the experiment by surrounding the tube with an atmosphere of ether, showing that under these conditions the elasticity of the water skin relaxed and was no longer able to support the column of water. These experiments, together with others, led up to the elastic nature of the film of soap-bubbles. Prof. Boys experimented upon these with the facility of an expert. He blew bubbles inside one another; he showed how a bubble can be stretched, how it can be rolled up and down inside another without breaking; and how it can push another bubble about without ever really touching it. He concluded by showing that two bubbles can be made to coalesce into one by electrifying them; whereas, if one bubble is inside another, the small electric discharge will have no effect upon the inclosed bubble.

In the course of a lecture to "young people" at the London Institution, Dr. A. H. Fison referred to the phenomenon of the persistence of vision, explaining why the image of an object formed on the retina did not immediately disappear when the object was removed from the sight, but gradually faded away until in about one-quarter of a second it had completely vanished. It was for this reason, he said, that the eye could not follow very quick motions, and that a red-hot poker swung round rapidly gave the impression of a circle of fire. After illustrating this persistence of vision with several experiments, the lecturer said it was the basis of a method of mixing colours—that known as Newton's whirling disc—which he proceeded to describe. If a disc, painted in stripes with the colours of the spectrum, were rapidly rotated, no single colour was distinguishable to the eye, but the mixture of all the colours gave the sensation of white. Dr. Fison showed several examples of this mixing, and pointed out that a given tint could be matched by several different combinations of colours, though the matching might not be correct in every light. The general law of colour mixture was next set forth, and it was explained that every colour in nature could be produced by the combination of red, green, and violet, which, on that account, were termed the primary colours.

The paper to be read at the meeting of the Society of Arts on Wednesday evening, Jan. 17, will interest many people, as the subject is "Ventilation without Draughts," by Mr. Arthur Riggs. The Cantor lectures on "The Nature and Yield of Metalliferous Deposits," by Mr. Bennett H. Brough, commence on Monday, Jan. 22.

According to the Vienna correspondent of the *Standard*, the case of Prof. Samuel Schenk, of the University of Vienna, whose theory concerning the determination of sex created, some two years ago, a sensation in the scientific world, and whose book on the subject was censured a twelvemonth later by the disciplinary Council of the College of Professors of the University, is again attracting attention. The Council addressed a petition to the Ministry of Public Instruction asking that the professor might be removed from his chair and from the management of the Embryological Institute at the University. This petition has now been acceded to, and Prof. Schenk has been removed from the Institute and given leave of absence, as professor, for an indefinite period, the Faculty of Medicine at the same time inviting him to apply officially for a pension. The professor has been at the head of the Embryological Institute for twenty-six years, and though his theory may be considered defective, and the publication of it premature, he can scarcely be held any more culpable than Prof. Koch, of Berlin, whose cure for tuberculosis was open to the same objections.

The earthquake in the province of Tiflis seems to have been very severe, as many villages have been destroyed, and the bodies of over 800 residents have been discovered and recorded. It appears that other shocks followed the major one.

It is stated that the South-Eastern and Chatham Railway has made arrangements with the Wireless Telegraph and Signal Company for the Marconi system to be used on the company's Royal Mail steamers between Dover and Calais, and also on their Royal Mail steamers between Folkestone and Boulogne—"an innovation of great importance for the safety of the travelling public by the short sea routes." One pole erected at Dover will command both fleets either in crossing the Channel or in port the other side of the water. Owing to the exceedingly short distance across the Channel, the ships' masts will be sufficiently high for a receiving pole across the Channel to be dispensed with. When the pole has been erected at Dover, communication by wireless telegraph can be maintained with the Ostend boats, if the Belgian Government desire; but in their case, the distance being greater, the erection of a pole at Ostend will probably be necessary. It is announced, however, that the wireless telegraph will be used for service purposes only, and will not be available for private messages.

It has been decided that the vessel which is to make the attempt to find the Antarctic Pole—or to explore the regions of the South Pole—shall be of timber, as iron would be possibly detrimental to the magnetic observations, which are really the objects of the expedition, though there is a hope that something may be done to examine, if not to explore, the land. The vessel is to be something like the *Fram*, and will be constructed to carry coal and other stores sufficient for three years, and will contain accommodation for five scientific observers, five officers, and a crew of about twenty men. The vessel will be rigged as a three-masted schooner, and will be illuminated throughout with electric light. The Howaldt Shipbuilding Yard, which is under a contract to have the ship built by May 1st, 1901, and fitted out not later than the end of August, 1901, has already begun the construction.

The scientific culture of the beet does not seem to have been acquired in California, as the average yield comes out, it is stated, at less than 8½ tons per acre, which cannot well be remunerative. The fact appears to be that the beet does well only on certain soils and in some climates; but in the United States the area last year was, it is stated, 144,100 acres, the yield of roots 1,220,000 tons, and the production of sugar 122,000 tons, which is a great increase on the two previous years. The actual results of last year's work cannot be known at present, but, looking at the vast area of the United States, it would seem that beet-roots for sugar-making could be grown profitably in some districts.

THE total output of the locomotive-building shops of the United States—outside of the railway shops—during the year just ended was 2,473 locomotives, the largest number yet recorded in a single year. The increase over last year is 598 locomotives, or about 32 per cent., and is about 10 per cent. higher than the next best year, 1890, when the total output was 2,240 locomotives. Of the 2,473 locomotives built last year, 339, or nearly 14 per cent., were compounds. In 1898 the output of compounds was 373, or 20 per cent. of the total output.

Incandescent Lamps Without Gas.—Many dwellers in the country who are debarred the luxury of gas will hail with pleasure the advent of a new lamp, capable of rivalling the incandescent gas-burner, but without the need for gas. Such a lamp has been devised by M. Denayrouze, and was recently exhibited before the French Society of Civil Engineers. The light of an ordinary fishtail burner is due to the incandescence of particles of carbon reduced from the coal-gas by the act of combustion, and rendered white-hot by the heat thereby evolved. According to St. Claire-Déville, there is only about from three to six per cent. of carbon in coal-gas, the surplus hydrogen being able to raise to white heat a far larger proportion than this if it were present. This fact is made use of in the Welsbach burner, which, from a given amount of gas, produces about five times more illumination than if burnt in an ordinary fishtail or bat's-wing, or even an Argand burner. Many burners have been devised to cause an incandescent illumination from alcohol or petroleum, &c., as the combustible, but, so far, with little practical success. M. Denayrouze has hit upon a combination of the two systems. He uses alcohol to which a hydrocarbon has been added; in heating the mantle carbon is deposited upon it, and along with the mantle itself is rendered incandescent, and thus a double source of light is provided. The lamp was a success; but the inventor kept to himself all details as to what form of carburetting agent was supplied. Still, it is probable that an invention of such value will be taken up by the manufacturers and placed upon the market, if in its present shape it is a really practical lamp.—*British Journal of Photography.*

LETTERS TO THE EDITOR.

[*We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.*]

All communications should be addressed to the EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

*** *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks; a vice from whence great inconveniences derive their original." —*Montaigne's Essays.*

ERRATUM—THE SOLAR PARALLAX—ATMOSPHERIC TIDES — BIBLICAL SCIENCE — BINOCULAR MICROSCOPES — PHOTOGRAPHY AT LICK OBSERVATORY: 57 M. LYRÆ; H IV. 13 CYGNI, AND 13 M. HERCULIS—LUNAR SEAS AND RAYS—FIELD ARMOUR — THE TWENTIETH CENTURY — THE MOON AND THE WEATHER — LONGITUDE — SUN'S ALTITUDE AND AZIMUTH — ARTIFICIAL OYSTERS.

[43189.]—WRITING, as I perforce always do, the second half of my letter (43145) in very great haste, I find that I made a most astonishing *lapsus calami* in the third paragraph of column one on p. 450, where it appears I must have written that when a clock showing *accurate* Greenwich time marked 10h. 2m. 10s. it was 10 p.m. at Greenwich!—an allegation which for pure idiocy it would be hard to beat. Of course, the "*Greenwich Mean Time*" should be "*Local* Mean Time." As "E. P.'s" star will not cross the Greenwich meridian until 2m. 10s. after it has been on that of Maidstone—and it will do so at 10h. 2m. 10s. p.m. there—at the instant of its transit at Maidstone, a clock showing *Greenwich* Mean Time should mark 10h. 0m. 0s.

I do not quite understand the sixth paragraph of your "Scientific News" on p. 448, in which it is stated that: "The parallax of the sun is, *according to M. Bouquet de la Grye*, 8·80″±·01. It is the words I have italicised that puzzle me, because this was the constant determined on at the International Conference on Fundamental Stars, which met in Paris in May, 1896, and which appears in the *Nautical Almanac*, the *American Ephemeris and Nautical Almanac*, the *Connaissance des Temps*, and the *Berliner Astronomisches Jahrbuch* for 1901 and henceforward. I remember Dr. Lescarbault's "discovering" the planet Saturn! but M. Bouquet de la Grye is a man of great astronomical eminence, and of very different calibre to the Orgères practitioner.

I remarked upon the fallacy underlying the craze on the subject of the Moon's Tidal influence on the Weather in the seventh paragraph of my letter (43145) on p. 449, and on the very next page (450) I find Mr. Munro returning to the subject in letter 43148. He is apparently in ignorance that years ago the late Prof. Daniel conducted an elaborate series of barometrical experiments at Box Hill in Surrey, and showed conclusively that there *are* semi-diurnal tides in the atmosphere due to the moon. But they can only be detected at a height, more or less considerable, above the earth, because at the sea-level the greater height of air accumulated beneath the moon would, on the whole, weigh no more than the shorter column elsewhere; since every particle under the moon (and, of course, the mercury by which we weigh it) would, of course, have its weight diminished by the moon's attraction opposing that of the earth. It is needless, moreover, to add that the *very* slight indications of a lunar atmospheric tide, even discernible on high mountains, are largely masked by a variety of extraneous causes. Perhaps in noticing Mr. Munro's letter I may be allowed to enter a gentle protest against his peroration. The trash which he criticises can no more be legitimately designated "absurdities in *astronomy*" than can the doings of the "Christian Scientists" and the "Peculiar People" be dignified with the appellation of absurdities in medicine. No *astronomer* ever penned any of the drivelling nonsense to which your correspondent takes such righteous exception. When anyone worthy of that designation does so far forget the rudiments of his science as to pen cognate stuff, it will be quite time for Mr. any Munro to talk about setting "the science up to ridicule" and lowering "it in the estimation of the laity." It is not so very long since an unfortunate creature at Portsmouth wrote to Sir John Gorst threatening him with the pains and penalties of an obsolete statute which made it illegal to teach in schools that the earth is round. I wonder whether this lowered astronomy "in the estimation of the laity" or not?

I venture to think that the signature appended to letter 43154 (p. 453) gives but scant idea of the real value of that communication, which is worthy of the serious consideration of all those who are so fond of lugging archaic Biblical literature into discussions which have reference to matters of pure science, and to them alone. I can entirely sympathise with those who are restrained from entering into a legitimate scientific discussion for fear "of offending many devout and worthy persons who are still deeply pained at any doubt thrown on the entire infallibility of the Bible"; but the amount of crass ignorance with reference to that collection of books is absolutely appalling. What Niebuhr did for Roman history has been done, and continues to be done, in separating what is purely legendary or mythical, from what may be regarded as historical, or quasi-historical, in the Hebrew records; but all this is caviare to the general, who read the Pentateuch as though it were an historical record in the same sense as a *Times* report of a public meeting or an inquest. Surely such who have so far proceeded in innocent ignorance may well pay deference to the publicly-expressed opinion of dignitaries of the Church, who have made a most special study of the books in question. Listen, then, to the Bishop of Worcester, Dr. Perowne, who (while Dean of Peterborough) said, at the Manchester Church Congress: "I hold it to be established beyond all controversy that the Pentateuch in its present form was not written by Moses"; or to the more recent utterance (albeit in somewhat more involved and ornate language) of the Dean of Canterbury, Dr. Farrar, in his luminous and instructive work "The People's Bible History": "The faintest semblance of harmony between Genesis and physical science can only be obtained by a licentious artificiality and casuistry of exegetic invention." Now let me reiterate: these are not the rant of screeching secularists in Hyde Park, but the deliberately uttered opinions of two very high dignitaries of the Church of England. The mischief done by presenting to people as necessary to their salvation the myths of the serpent, the ark, the pillar of salt, and all the rest of it, is absolutely incalculable. Your clever school-board pupil, when he finds out how absolutely mythical all this is, is but too apt to class the whole of the Book of books, in which it is bound up, in the same category; and so to root up the wheat with the tares, and make wreck of his faith altogether. At all events, let us, who write letters in these columns, resolve that they shall be strictly scientific ones, and that we will not be guilty of the childish folly of supposing that a question of pure physical or natural science can, by any possibility, be decided by a text. If people must drag Hebrew or other myths into the discussion of their theses, for goodness, sake, let them send their letters to the *Church Times*, *Record*, *Tablet*, *War Cry*, or *Sword and Trowel* as the case may be, and not to the ENGLISH MECHANIC.

[Since the above was written—and almost certainly in print—I have seen letter 43187, on p. 474. It seems to me that Mr. Garbett labours under the delusion that he proves a thing by simply repeating it. "The days of creation," he says, "were lengthy ages." Were they? If so, Exodus xx. 8—11 is pure nonsense. Again, "That the earth was formed before the sun is 'Biblical science,'" is true enough; but nothing can be more glaringly false than that it is "also recent *science* of yesterday"—or of any other day. It is the craze of a Biblomaniac. As for the sickening rubbish about the remains of the Ark on Mount Ararat, did not Mr. Bliss (in letter 42850 on p. 136) explain how the story about "Archdeacon Nouri," and all the rest of it, was a hoax perpetrated in 1883 by the *New Zealand Herald*? But it seems that the making of fools is not confined to the 1st of April.]

I know nothing of the particular form of microscope devised by Dr. Emil Berger; but "Myops" (query 97337, p. 457) surely does not imagine that it is the first successful attempt to obtain stereoscopic vision with that instrument! Why, as far back as 1851—49 years ago—Prof. Riddell, of New Orleans, devised a binocular microscope for exhibiting objects stereoscopically, or apparently solid. He was speedily followed by your correspondent, Mr. Wenham in London, and by M. Nachet in Paris. Then we had Stephenson's form, and later still the binocular eyepieces of Tolles and Abbe. The idea of there being any novelty in the mere obtaining of stereoscopic vision by a binocular microscope is simply ridiculous.

Reading the, evidently, necessarily curt reference to the work of the Crossley reflector at the Lick Observatory in your "Progress of Astronomy in 1899" on p. 462 suggests to me to say that the success achieved by Prof. Keeler with the two nebulæ you mention, and that of Mr. H K Palmer with the famous cluster in Hercules are of so highly interesting a character, and have added so appreciably to our knowledge of the objects that he has been photographing as to render them worthy of more extended notice than space probably prevented you from devoting to them. Taking, then, the *Astrophysical Journal* as my authority, and the groundwork of my remarks, I may say that the familiar Ring Nebula in Lyra (M. 57) has been photographed with the happiest results; albeit the focal length of the Crossley mirror is less than six times its aperture, and in order that the photographic and optical resolving powers of a camera may be equal, its focal length must be from 30 to 60 times its aperture. Of course, this short focus shortens the exposure, which was only ten minutes for the best general picture of the nebula, whose major axis on the photographic plate in the primary focus of the telescope is only 0·08in. If the focal length of the telescope were increased four times, the image would have a diameter of about 0·32in.; but then a three-hours' exposure would become necessary. Let us, however, see what Prof. Keeler has done with the instrumental means at his disposal. *Imprimis*, he finds the actual shape of the nebula to be oval, rather than elliptical with its more pointed end towards the N.E., and from both sides project faint fringes of nebulosity. The ring itself seems to be made up of several narrower bright rings, interlacing somewhat irregularly, and with the spaces between them filled with fainter nebulosity. One of these forms the outer boundary of the preceding edge of the main ring, and becomes very bright about the north end of the minor axis. The dimensions of the rings, I may here observe, are perceptibly greater in photographs than they have been found to be visually with a micrometer; but if the exterior fringes of nebulosity are chiefly formed of hydrogen, which is visually weak but photographically strong, this could be accounted for. Perhaps this, too, may account for the extraordinary actinic power of the little central star within the ring, which was faintly visible on a plate exposed for only 30 seconds. Prof. Keeler thinks it possible that such photographic strength may have its origin in the ultra-violet spectrum of the hydrogen series. Another ring nebula very much less known, H IV. 13, has also been photographed. This is a nearly circular ring, with a major axis = 42·5″ and a minor one = 40·5″. A star on the ring, first seen by Lord Rosse, was very conspicuous, but a second one that he figures does not appear on the Lick photographs at all. And last, but by no means least, we have Mr. Palmer's important research on the "Distribution of Stars in the Cluster Messier 13 in Hercules." Working upon a plate to which an exposure of two hours had been given, and which had been so lightly developed that the minute stars were not obscured by the brighter ones, and even the middle of the cluster was resolvable (!), over five thousand stars were counted on the plate. The stars on the plate, of which there are 5,482, are fairly sharply divided into two distinct orders of brightness, 1,016 being classed as bright, and 4,466 as faint. Without entering into detail, which must be sought in the *Memoir* itself (*Astrophysical Journal* for November, 1899, pp. 246-254), I may just say here that some of the results arrived at were of a very unexpected character. It might, for example, have been supposed that in the very middle of the cluster, where the stars are so very closely packed, the faint stars would have been hidden by the bright ones, and that where faint stars are scattered very thickly the bright ones would appear nebulous; but the most careful examination by Prof. Keeler and Mr. Palmer have sufficed to convince them that there is no true nebulosity in any part of the cluster; nor, I may add here, is it discernible in any single one of the clusters which they photographed. In Mr. Palmer's own words: "We do not, of course, assert that there is no nebulosity in this cluster, or in others of a similar character; but we think that the existence of nebulosity has not been proved." Lord Rosse's three dark lanes round the most compressed part of the cluster are easily visible on its photograph.

Premising that I do not see *Knowledge*, and that my acquaintance with Mr. Tepper's paper therein is derived solely from Mr. Elvins's letter (43162) on p. 470, I would say that Mr. Tepper must be a gentleman of the most vivid imagination. That both air and water have existed on the moon may, I think, be regarded as practically certain, albeit from her small mass she would not, so to speak, have much hold over an atmosphere; but that animals and plants akin to terrestrial ones ever existed we have not a vestige of proof. They may, or they may not; but we are in no position to assume definitely that they did. I would next remark that it is abundantly obvious that Mr. Elvins has never read Prof. Darwin's most masterly treatise on "The Tides," because that distinguished philosopher expressly contends that the moon did rotate upon her own axis rapidly in past time, and that tidal friction gradually impeded her rotation. It would repay your correspondent to read his book. Now, though, for (what are presumably) Mr. Elvins's own ideas. When he talks about large meteors falling vertically on the lunar surface and producing such formations as Copernicus, Kepler, and Tycho, has he ever reflected for one single instant on the size of those formations? Is he aware that the diameter of Copernicus

is 56 02 *miles*, that of Tycho 54·28 miles, and that Kepler is 21·71 miles across? What sort of a meteor, and what must be the size and mass of it, to make a hole 56 miles in diameter in the moon's crust, and what does he conceive would be the effect on the moon, not merely locally, but as an entire body, of the impact of such a stupendous planetoid striking her with ordinary meteoric velocity? Furthermore, it seems impossible that your correspondent can ever have examined the formations of which he speaks with adequate optical power, or he could never have supposed that their regular structure was the result of a fortuitous blow or blows delivered with planetary velocity. And if this idea be a wild one, what shall we say of a meteor or meteors furrowing out white streaks in carbonaceous dust while moving nearly horizontally across the moon! (?) Does your correspondent know what the lengths of these streaks, or the more prominent of them, are in miles, and does he suppose that the meteors could or would pass horizontally (of course touching the moon's surface) for anything approaching to such distances, without being brought to rest by friction? Why he—or Mr. Tepper, I don't know which—talks as though the meteors assumed the form of the blade of a stupendous plough-plane, and were carried across the face of the moon by cognate mechanism. Of course, I only know Mr. Tepper's hypothesis as expounded by Mr. Elvins; but in the form in which it appears it seems to me arrant nonsense.

Letter 43172, on p. 472, bears internal evidence that Mr. Lawler is not—nor ever has been—a soldier. Thanks to the Creusot Works, and Krupp's at Essen, the Boers have better artillery than we have, and I should like to know what he thinks would be the effect of a shell dropping just inside of his shield which unfortunate Tommy Atkins is delineated as pushing up a steep hill before him. Nicely out of breath would the rank and file be by the time they reached (if ever they did reach) the Boer entrenchments. Surely your correspondent does not think that the Boers would reserve their shell-fire until our infantry came to close quarters! or that they would ever face British troops at all under equal circumstances. They are much too artful for that. Securely hidden in their trenches, or behind masses of rock, they, good shots that they are, can pick off at leisure men to whom they are utterly invisible; but when they see the glint of our bayonets they promptly put into practice the dictum of Goldsmith: "He that fights and runs away may live to fight another day." The shields on trucks are all very well on an armoured train when it is attacked by rifle-fire only, but would terribly hamper and become a source of danger to men charging up to an intrenched position to take it. A 15-hand cob for each man would be of infinitely more service to a battalion of infantry in the Transvaal than all Mr. Lawler's shields put together.

I think that a very little consideration will show Mr. Stanley (letter 43180, p. 474) that there really never can have been a year 0. The first year of the Christian Era *must* have been 1 A D, and supposing such year to have commenced on Jan. 1, on June 1 (i.e., June 1, A D. 1), a child born on the 1st of January could only be 5 months old, and *not* 1 year and 5 months old as it would have been had the era begun with 0. We must go on to June 1, A.D. 2, before it could have attained the latter age. This being so, had our hypothetical child become a centenarian he could not have *entered* his 100th year until the year 100, nor his second century until the year 101, and so on. If, then, the second century did not commence until the beginning of 101, the 20th century cannot begin until 1901. Those who reckon from (180)0 beg the whole question.

"A. B. M." (letter 43182, p. 474), in his graciously patronising manner, opines that a "judicial quality" and "philosophical suspense of judgment on a matter in the course of elucidation is not always conspicuous in the utterances of 'F.R.A.S.,' and . . . may possibly be somewhat foreign to his temperament"—which, being interpreted, signifies that "F.R.A.S." refuses to accept, open-mouthed, any wild hypothesis which meteorological observations continued over a very long series of years have shown him to be absolutely unproved—not to say as absolutely unfounded—but which commends itself to "A. B. M." because, doubtless unconsciously, he *wishes* it to be true. Would your correspondent be surprised to hear that I have sat in a judicial capacity for many more years than I should care to count, and hear and adjudicate on more evidence in six months than, in all human probability, he has ever listened to in his whole lifetime?

Perhaps I may explain to "Argentine" (query 97352, p. 479) that it is impossible to determine Longitude without in some way getting Greenwich Mean Time to compare with the local instant of observation. The only way of employing a 6in. transit theodolite for this purpose that occurs to me would be to use it to observe some of the moon-culminating stars, of which details will be found on pp. 454 to 482 inclusive of the *Nautical Almanac* for the current year. I do not quite understand query 97353 on the same page.

As "Fleur-de-Lys" (query 97356, p. 479) says that he has no means of access to the back number of the ENGLISH MECHANIC to which I referred him for an answer to his original query, I will myself turn back to what I there wrote and give him the benefit of it: Call the Latitude ϕ, δ the sun's Declination, P his hour angle, Z his zenith distance, and A his azimuth. P M is an arc which we shall use in our calculation, and we get it by the following equation—

(1) tan. P M = cos. P. cot δ. Then—
(2) cos. (P M + ϕ) cot. P. cosec. P M = cot. A.
(3) sin. (P M + ϕ) sin. δ sec. P M = cos. Z (or sin. altitude).

Let us imagine that in London (lat. 51° 30′) on June 20 that the Sun was 2h. 20m. past the meridian (= 36° in arc), his declination being 23° 27′ 16″ N., what were his azimuth and altitude? First we want our angle P M (equation 1).

P = 36°	= cos.	9·907958
δ = 23° 27′ 16″	= cot.	0·362643
61° 47′ 45″	tan.	0·270601

Note that had the latitude been North and the sun's declination *South*, cot. δ would have been negative and P.M. must have been taken in the second quadrant, and instead of being 61° 47″ 45′ could have been 180°—61° 47′ 45″ or 118° 12′ 15″. Then by equation (2)—

P M =	61°	47′	45″		
ϕ =	51	30	0		
(P M + ϕ) =	113	17	45	cos.	9·597123
P =	36	0	0	cot.	0·138739
P M =	61	47	45	cosec.	0 054891
Azimuth West of South	58	17	52	cot.	9·790753

By equation (3)—

(P M + ϕ) =	113°	17′	45″	sin.	9·963068
δ =	23	27	16	sin.	9·599905
P M =	61	47	45	sec.	0 325492
					9 888465
Z D	39	19	48	cos.	
Or altitude	50	40	12		

As query 97358 on the same page is primarily addressed to my very competent brother correspondent, "Arcturus," I will not answer it unless he declines to do so.

Query 97363, p. 479, reminds me that I have been told that if you order oyster-sauce at any of the cheaper London restaurants, you get mussels.

A Fellow of the Royal Astronomical Society.

THE SATELLITE OF NEPTUNE.

[43190.]—"ELL HAY," in your issue of to-day (Jan. 5) gives most of the particulars asked for as to his observations of the satellite of Neptune, but omits to specify whether it was held steadily or merely glimpsed. In his original letter he stated the reflector ($5\frac{1}{4}$in.) "showed the satellite, though still very faint," and my remark referred to its being seen steadily with so small an aperture. Ward only glimpsed it with the 4·3in. Wray refractor, though he appears to have seen it on several nights early in 1877, and gave remarkably close approximations of the positions and distances by eye estimation, without knowing, at the time, the positions from the ephemeris. By the way, may I ask, who now calculates the ephemerides of the satellites of Jupiter, Saturn, and Neptune, since the decease of that admirable computer, the late Mr. Albert Marth?

Can any of your readers give the positions of the Satellite of Neptune on the nights of Nov. 12 and Nov. 18 last, when "Ell Hay" estimated the position-angle as 250°, and distance as 12″ approximately? Of course, the satellite would not be in the same exact position on both nights, as one revolution is a little under six days, but they are close enough for the present purpose to identify it from a faint star which might happen to be near the planet. The observation of Nov. 18 was certainly remarkable, as the moon would be only about 10° to the west of Neptune at midnight, and she occulted him on the following evening between 6 and 7 o'clock, but it was cloudy here.

With reference to the remark of "Ell Hay" regarding the proportional areas (30 to 18) of his $5\frac{1}{4}$in. Newtonian, and the 4·3in. refractor used by Ward, the proportion would be reduced by the loss of light by reflection in the Newtonian, and consequently less favourable to "Ell Hay," who must have exceptionally keen vision to have seen the satellite (even under best conditions of the polish of mirror), especially so near to the moon, when the latter was only a day and a half past full.

There is a light test at present available for the $5\frac{1}{4}$in. in the field near the triple star ι (Iota) Orionis. It is a faint pair of stars numbered 719 and 725 by Bond, when plotting the stars seen with the 15in. Merz telescope of the Harvard Observatory in the region around the Great Nebula of Orion half a century ago. The magnitudes were given as 14·8 and 12·3 respectively in Argelander's scale. This pair was picked up by Ward, independently, in 1878, with the 4·3in. refractor, and measured by Dr. Copeland, with the 15in. Grubb refractor at Dunecht, of which full particulars are given in *Knowledge* for January 4, 1884, with diagrams.

Neptune.

LUNAR ECLIPSE OF DEC. 16.

[43191.]—THE chief features of interest in the recent lunar eclipse as noticed by me were:—

(1) The penumbral shadow was noticeable only across the equatorial regions of the moon, more particularly the northern, while the poles remained quite bright and white by contrast.

(2) The limb of the true shadow showed decidedly circular before reaching Aristarchus.

(3) The colour of the shaded portion of the moon was dark black-grey during the earlier and later phases of the eclipse, and became lighter and of an ochreous colour as the phase increased, being a bright orange-ochre at mid-eclipse; the shades of colour then recurred in the reverse order as the eclipse waned.

(4) The details of the features of the moon were curiously irregular in visibility, at one time being quite distinct, at another totally invisible, without any apparent cause, such as interference by clouds. This phenomenon occurred only during the early and late stages of the eclipse, while the shadow was of a dark grey colour. During the middle portion of the eclipse all the prominent details were plainly visible.

(5) The colour of the shadow was more ochreous with higher powers, more grey with lower powers.

(6) The penumbral shadow immediately after the eclipse in the region of the last contact of the true shadow was of a decidedly ochreous tinge with a power of 75.

(7) In the one occultation I observed (12.58), the star appeared to hang just *within* the moon's dark limb for an appreciable moment before disappearance.

(8) The uneclipsed portion of the moon appeared to be larger than ·005.

I was using a 5in. refractor with powers of 40 and 75, and occasionally 150.

Rontenburn, Largs, N.B. **N. Maclachlan.**

LUNAR MARKINGS BY METEORS.

[43192.]—I AM interested to see that Mr. Elvins (in letter 43162, p. 470) suggests that the rays and ring formations on the moon may have been caused by meteors. With regard to the lunar rings the subject was very lengthily discussed a short time since in the E.M., between myself, supporting the meteoric theory, and "F.R.A.S.," Mr. Ellison, and others opposing it. If Mr. Elvins is sufficiently interested in the subject, he will find the discussion referred to in Vol. LXVI. pp. 297, 318; Vol. LXVII. pp. 150, 173, 175, 219, 246, 265, 335, 360, 381, 402, 404, 476, 525, 548, 569; Vol. LXVIII. pp., 12, 140, 234, 325, 349, 393, 439. The theory had been suggested by Proctor, but I was not aware of it when I raised the discussion.

With regards to the suggestion that the rays were caused by meteors ploughing up the surface, I think the fact that the rays are more visible under the direct than under the oblique light of the sun is against it. All superficial disturbances are more apparent under oblique illumination. These lunar rays always appear to me like reflections of sunlight from the lofty peaks of the ring mountains, only that they do not spread like rays of light, and that they in many cases follow the rotundity of the moon far out of the reach of straight lines drawn from the reflecting points. Is it possible that as these rays are reflected in vacuum they may possess the peculiarities of rays produced in vacuum—i.e., that the light does not disperse, and is, I believe, under certain circumstances subject to lateral deflection by magnetic attraction?

R. P.

THE QUADRANTIDS—SUNSPOT COLOURS.

[43193.]—A BRILLIANT meteor was seen here at 11h. 45m. on Jan. 2, 1900, as bright as Sirius, of the same colour as that star, and leaving a faint train. It came from midway between θ and ι Draconis, shooting up under γ Ursæ Minoris towards Polaris. The sky was then watched until 12h. 45m., and five more meteors were recorded, all Quadrantids. The peculiarities of those meteors seen were thin blue-white colour and the faint train some of them left.

In the report of the recent B.A.A. meeting several members remark on the colours surrounding sunspots. I have sometimes seen them by projection, but never direct. I conceive that the atmosphere has something to do with their appearance, for they are more pronounced on some occasions than on others. On one occasion I was showing a group of small spots to a friend (projection method)

and the colours were so pronounced as to cause comment. Red seems to be the predominant colour, at least, so far as my short experience shows.

Erratum.—In letter 43164, p. 470, in first column of table, 1889 is erroneously printed for 1899.

Earlsfield, S.W. **Silverplume.**

THE QUADRANTIDS, 1900.

[43194.]—IN accordance with my endeavour to supply notes on the seven principal meteoric showers of the year, I forward a table giving particulars of twenty-five meteors observed here on January 2.

No.	1900.	G.M.T.	From.	To.	Mag.	Dur.	Description.
		h. m.	° °	° °		s.

The watch kept was from 11h. 30m. to 13h. 0m., and the time of observation with a sky practically free from cloud was 1h. 15m. Clouds prevailed chiefly about 12h. 20m.

The radiants found were—

22° + 67° (Nos. 8, 16-18)

230° + 54° (Nos. 3-7, 10, 12, 14, 15, 22-25).

To the latter, the Quadrantid radiant, belonged four out of the five first magnitude meteors recorded.

A flash, probably due to the appearance of a bright meteor, was noted in a break in the clouds at 12h. 23m.

Other watches, proposed with a view to ascertaining the duration of the shower, were useless on account of unfavourable weather.

Walter E. Besley.

Clapham Common, Jan. 5.

METEOR.

[43195.]—BRILLIANT meteor seen here at 2.57 p.m. like a ball of burning zinc, emitting yellow sparks; seemed to come from S.W. to N.E. Vanished almost direct under moon. **Thos. Parker.**

Penshurst, Tuesday Evening, Jan. 9.

SCHAEBERLE, ABERRATION, ETC.

[43196.]—"A. S. L.'s" opinion that this matter is "made too much of" is that of most who are able to judge. It is a theoretical rather than a practical aberration; otherwise our o.g.'s and mirrors could not divide to the theoretical limit. Theoretically, it is present in every optical lens, single or compound, and it has been shown it must be in a greater degree with a refractor than a reflector, and it is well known that the reflector will give a smaller image of a star than a refractor of same size.

I think there is a very simple way of testing whether this aberration is of practical importance or not. I will ask "A. S. L.'s" opinion. This aberration by the longer rays from the edge of any lens causes an increasing enlargement of image, and consequently an overlapping from centre to edge. Now if we put an eccentric stop—say an 8in. or 9in. stop—on an 18in. mirror or o.g., the one edge of this 9in. stop touching the centre of the lens and the other the margin, should not the image of a star be, not a round one, but an oval one? The bulging out and the rings also eccentric and enlarging towards that edge corresponding with the rays coming from the edge of lens. Theoretically, such an image and result ought to happen, but practically nothing of the kind does happen, for a star is not only round, but the rings are concentric and regular as if no stop were used.

To give "A. S. L." some of my own experience of glass discs, I may say at once that I have found cast ones the best on the whole, though for ordinary purposes and small sizes good plate discs will do, especially for long focus. The plate when rolled induces a strain in the texture not easily tempered out. The cast discs of the good light plate metal are harder, and therefore take a better polish and give more light. They are less labour to shape up, too, as the edging is the trouble with amateurs. The *very* green discs have too much soda in them, and will actually corrode on the surface. I once had the mice get into my boxes where I keep finished mirrors, and their urine spoiled me £100 worth of mirrors; it corroded the surfaces, the same, I suppose, as fluoric acid would.

I commenced, nearly forty years ago, with plate discs; I then tried cast-flint discs; these were easily annealed, but for large sizes were too heavy and too soft. I then went to cast plate, and Chance took a deal of trouble to suit and please me: but good discs were costly and very rough. I am now on the last of a batch of 18in. discs, which cost me £9 each, but they are good. To get neater discs and cheaper I went to the Continent. But soon I was called upon to make some large Cassegrains, &c. I soon found, to my cost, that the discs, though very well annealed, would not stand the boring out the centre hole. So after that I had all specially prepared, and had the hole cast in them. I found they would not stand even the truing of the hole (which I did with a diamond tool), unless very specially made. I have recently made a 20in. photographic mirror of 90in. focus, a fellow disc to a 20in. I made for Dr. Roberts; the discs were very fine, and would bear turning like a disc of metal.

G. Calver.

THE LUNAR RAYS: A NEW THEORY.

[43197.]—MR. A. ELVINS (letter 43162, p. 470) has suggested that an interesting discussion may arise in "Ours" respecting those mysterious bright markings on our satellite which are known as the "lunar rays." We hardly know enough about the constitution of the moon to assert anything as a fact, and all the theories which I have read concerning the rays fail to account for what is actually observed with the telescope, and become untenable when considered in connection with all the attendant circumstances. For instance, the theory that the rays are cracks in the lunar crust, through which semi-liquid matter has welled up, seems scarcely tenable when we observe that the rays run in an unbroken line across not only the plains, but over the highest mountain rings and down the other side, and then straight on. The idea that they are deposits of volcanic dust from a line of lunar craters also fails, as I should expect to find that on the sheltered side of the mountains there would be a considerable break in the rays. Moreover, a continuous line of craters (which must all have been active about the same period), extending many hundreds of miles, and, in at least one case, extending some two thousand miles, seems very improbable. The theory of a deposit of cosmic dust ploughed into furrows or scattered around by the impact of meteors may account for some of the shorter rays, and for the radiating rays; but can we for a moment imagine a meteor ploughing a straight furrow for some two thousand miles over a spherical surface having so sharp a curve as that of the moon? Again, all these theories fail to explain why so many of the rays have disappeared in the equatorial regions, although the northern and southern portions are so plainly in evidence. Many of the rays look as though they had once been continuous, but had since been destroyed where they passed over the equatorial part of the moon.

Other theories being therefore dismissed as unsatisfactory, I venture to propound a new one, in the hope that discussion may bring out something that satisfies the requirements of the case.

It is believed by many of our scientific men that the moon is intensely cold. Prof. Very suggests that its night temperature is – 360° Fahr.; others have, I think, suggested at least – 500° Fahr. But there is good reason to believe that, in the moon's daytime, when it is exposed to the direct rays of the sun, it is subjected to an intense amount of heat in the equatorial regions.

Assuming that the moon once possessed an atmosphere—an idea which has something to support it—the question naturally arises: "What has become of that atmosphere?" Some have suggested that it may have been driven off into space; others that it may have been withdrawn into the interior of the moon, or round to the side which we never see.

Latter-day science has, however, demonstrated that our own atmosphere may be liquefied, and, from what I have read, I gather that it may be solidified by intense cold, at a temperature not so low as that which has been attributed to the moon. If, therefore, while it possessed an atmosphere the moon became sufficiently cold, it seems not unreasonable to suppose that its atmosphere may have been precipitated upon the lunar surface in the form of a dry powder not unlike very fine snow. Whilst the atmosphere existed, there were doubtless strong currents of wind blowing in various directions, especially in a line with each side of the mountain rings and peaks. This would, I think, cause the formation of a more dense stratum of atmosphere between the lines of the currents, and result in a much thicker deposit of atmospheric powder between those lines; and as the deposited matter would fall from a considerable altitude, and more thickly *between* the currents, there would be no break in the rays on the mountain sides sheltered from the wind. In the same way, wind currents blowing in various directions between the peaks of isolated mountain rings would form the radiating streaks which are now such conspicuous objects on the lunar surface. The intense heat to which the equatorial regions of the moon are exposed would melt or evaporate all but the thickest layers of atmospheric deposit, and many of the thinner layers in regions a little cooler. This evaporation, which may still be proceeding on a small scale during the lunar days, might produce that misty appearance which some observers have occasionally noticed in some of the lunar formations.

Thus, by this theory, we may account for the formation of the rays, both straight and radiating; for the fact that they cast no visible shadows; that they pass unbroken over high mountains, and are even seen in the interior of crater plains; that many of them follow the lines of successive mountain rings, and we also account for their relative fewness in the equatorial regions.

Last, but not least, we solve the problem of what has become of the lunar atmosphere! **Mark.**

THE TWENTIETH CENTURY?

[43198.]—IT seems to me that Wm. F. Stanley, (letter 43180, p. 474) confuses his argument by attaching a value to zero, instead of regarding it as a mere mathematical line, having, in chronology, no duration! When a child is three months old, it is a quarter of *one year* old, not a quarter of 0 year, which would be absurd. It only enters its second year *after completion* of the first, and would only enter on its second century, no longer a child, *after completion* of 100 years, entering this *on the beginning* of its 101st year. And as 100 years *must be completed* before the second century begins, so with the centuries 1900 years *must be completed* before the twentieth century begins.

Similarly, zero on the scale of a thermometer is an imaginary mathematical line, which, in practice, our senses, and the want of delicacy in our instruments, or rather, I should say, the intrinsic nature of such a line, preclude us from accurately observing, yet the fractions above or below zero, are not fractions of *zero*, but are fractions of 1° above or below zero.

Some people insist that we have already entered the twentieth century, and refuse to think the matter out, relying on the fact that the Prayer-book so decrees it, that the Act of Parliament (24 Geo. II. c. 23) declares that "the next century is from the year 1800 to the year 1899 inclusive," and that the German Emperor has given his adhesion to this. To such, I would commend the lines of Peter Pindar:—

"Thou think'st that monarchs never can act ill.
Get thy head shaved, poor fool, or think so still."

H. B. F.

[43199.] — THE letter of your correspondent, Wm. F. Stanley (43180) may be regarded as a fair sample of the persistency of error. It has frequently been pointed out that the year 1900 is the 1900th year; or, in other words, the number expressing it bears the same relative value as that used to designate the day of the month. Thus, when we write the present date 8/1/1900, we mean the 8th day of the 1st month of the 1900th year, and just as the day will not be completed till mid-

night, or the month till midnight of the 31st of January, so the 1900th year, that is, 19 centuries, will not be completed till the 31st December next. And whilst it is now 7 p.m. of the 8th of January, the time elapsed of the present year is 7 days 19 hours, and since the beginning of our era 1899 02135 years, the fractional part belonging to the 1900th year.

It may be pointed out, however, that in some parts of the *Nautical Almanac* we find a nomenclature which at first sight seems at variance with this way of stating the case, and which may possibly lend encouragement to views like those of your correspondent.

Turning to the *N.A.* for 1900, at p. 294 and sequitur, the mean places of stars are given for the epoch January 0 + ·313 day; and similarly at page 592 we find the year 0 A.D.; but when we examine these dates we discover that the symbol January 0 stands for mean noon of December 31, and the year 0 A.D. is what is commonly called in chronology 1 B.C. Again, on page 1 and pages 290 and seq., precession is reckoned from 1900·0, and it is clear from the context that this denotes mean noon of January 1, 1900. Why this is so stated is not clear, as, according to the common interpretation of the calendar, 1900 plus a fraction would denote that the date is in the 1901st year. Perhaps our friend, "A Fellow of the Royal Astronomical Society," will kindly enlighten us on this point.

Referring to Mr. Allen's letter (43161), the greatest phase of the lunar eclipse was observed here (latitude 53° 40′) in a clear sky, and the most striking feature which attracted my attention was the profile of the Doerfel and Leibnitz Mountains, which came out with a distinctness I had never before seen. About 1.15 a small star was observed close to one of the peaks of the Doerfels, and I had hopes for several minutes that I might witness an occultation by the mountain, and a subsequent re-appearance. In this I was, however, disappointed, as the star cleared the peak by a few seconds of arc, and disappeared behind the limb several minutes later. An observer several miles further north than my station might have witnessed an interesting sight. I observed the eclipse with a 5in. refractor, power 80. J. Watson.

[43200.]—In this discussion there is an aspect which I have not seen referred to. Searching where possible as to the order of chronological data, I could not in any case find that there was a year "nought," but always as "one," at the commencement of any great change. Take one instance: over a hundred years ago the great French Revolu- commenced its year one. Similarly from the instant our Queen began her reign it became: "In the first year of the reign, &c."

The year before our Saviour's birth has always been numbered B.C. 1, and the following year as A.D. 1; and, counting as we do as to our earthly rulers, the King of Kings began his reign at his advent as the year one.

In no chronological or legal case can I find reference to a year 0 or ½, &c.; but they are counted in the natural way—1, 2, 3, never 0, 1, 2, else 0 becomes 1. W. London.

DO ANTS HEAR?

[43201.]—The above question (p. 447) may be made either an academic or a practical one. I do not think it is quite rational to deny to any family of living creatures the possession of so elementary and vital a sense as that of hearing among themselves. As a beginner with the microscope, I remember conveying in a clumsy sort of way to the stage of that instrument a small party of ants (I have no doubt they were ants) which had lodged in a blossom of azalea I had put into my vasculum when in the country.

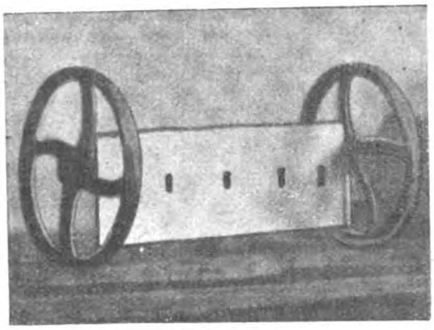
I had no sooner placed them on the stage than they naturally darted off in all directions. Wishing to secure one, at least, of the insects as an object, I turned it over on its back by means of a dissecting needle, when it lay helpless. Immediately I had done so, one of its fellows, which had been rushing off in a diametrically opposite direction, returned, gave the needed assistance to its fallen brother, and then (without sufficient judgment as it seemed to me) returned precisely as it had come. I felt so interested in this observation of intelligence and pluck, that I repeated the experiment with the same result. In each case the distance and direction of each from the other made it appear a necessary condition that these insects were able to communicate by the sense of hearing. Carlos.

A SIMPLE HYGROMETER.

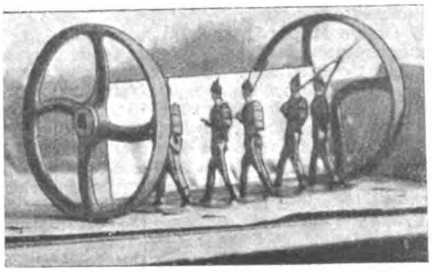
[43202.]—The "piece of twine" (p. 474) is not, any more than the catgut of the old-fashioned weather-house, a hygrometer. All that can be claimed for it is that it is, in a sense, a hygroscope; but even then, much depends on the kind of twine, and the process of manufacture. Some twine will not even act as a hygroscope. A simple hygrometer would be a very useful piece of apparatus in connection with many processes of the arts and manufactures;—mere hygroscopes are well known. See Ganot's "Physics" for an explanation of the discrimination. S. R.

PORTABLE SHIELDS.

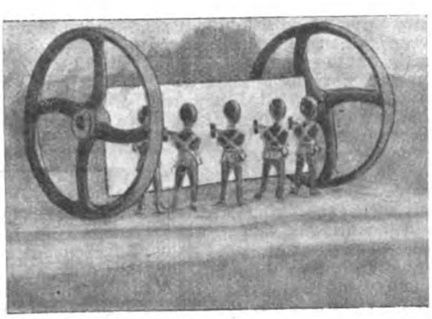
[43203.]—The sketches of Mr. Lawler (letter 43172) are somewhat similar to a design I brought



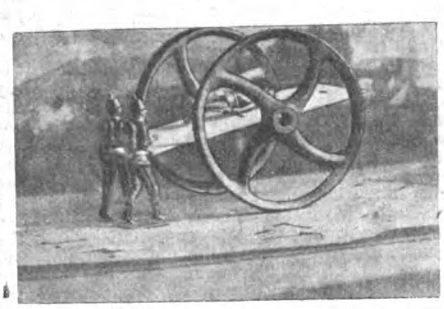
Portable Shield. This will swivel to allow passage over rough ground, or it may be lifted by two men over any rocks.



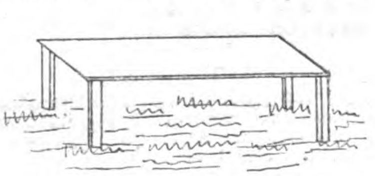
In use when advancing.



Firing.



Wheels may be taken off the ends and placed at the sides to make ambulance cart or waggon.



May be used also as camp table.

out five years ago, and which competent military critics told me would be invaluable in a war with the Boers. I send sketches. I may say that the War Office did not accept it when submitted for examination recently. Walter Bagshaw.

FIELD ARMOUR.

[43204.]—The number of repulses sustained by our troops in the course of the war in South Africa prove the truth of the statement put forward by your correspondent, Mr. Lawler, that the use of defensive armour of a portable kind is urgently needed to neutralise the immense improvements that have been made in offensive, that is, portable hand-carried weapons, whose motive power is in gunpowder. These have been made so accurate in aim, so quick in repeating the discharge with such an extended range of fire, that fighting in the open against cover means defeat to the attacking force.

To make defensive armour still more easily carried than already proposed, I venture to ask you to make known the following suggestion—to wit, to furnish each soldier with a shield carried wholly by himself, and consisting of two plates hinged together at right angles, wide enough and high enough to protect his body and head.

I would further corrugate vertically the two plates in corrugations about ½in. wide, so that the shield would not only catch the bullets at an angle of 45°, but that the sharp edges of the corrugations would eat or rasp off the leaden point or nose of the bullet striking it. This deflecting angle of 45° joined with the rasping action of the small corrugations will enable the shield to be made of correspondingly thin steel or iron.

I would supplement this short shield, which only covers the head and body, leaving the legs uncovered, by strips of steel covering the main bones of the legs, leaving the fleshy parts unprotected, as the present small-bore long range do not disable a man when they pass through flesh only. There would be a joint at the knee to cover that vulnerable part.

I expect that the armour may be made light enough to be carried at the rate of three miles an hour, the carrier's arms and ammunition being carried by another soldier following in his shelter close behind him.

Plymouth. W. B.

[43205.]—The army owe Mr. Lawler a deep debt of gratitude for his invaluable invention of iron shields for use at the front (43172, p. 472). I presume he has already communicated with the Commander-in-Chief on the subject. If the latter does not immediately insist upon Sir Redvers Buller and Lord Methuen "sitting tight" until they have been furnished with a sufficient number of Mr. Lawler's shields, he will be failing in his duty to the army and the country, and the country will insist upon knowing the reason why.

What I like about Mr. Lawler is that he does not claim impossibilities, for instance, as he admits "the ground would not permit of its (the shield) being always wheeled." Undoubtedly such is the case—e.g., at Belmont and at Colenso the troops would have found the wheels almost, if not quite, useless. In one respect, though, I think Mr. Lawler's scheme is open to criticism. His shield is not more than 4ft. high, otherwise, as he truly anticipates, it would be too heavy to carry. Therefore, to get the full benefit of it the troops also should be not more than 4ft. in height. This seems rather small for Englishmen. Sapper.

[43206.]—O'Dermid W. Lawler's sketches are somewhat comical, and I pity the two little fellows who are engaged in pushing the (necessarily heavy) shield up the hill. I say nothing of the military aspect of the case, but I am sure if the proposer had had (as I have had) to scramble up and down the rocky country out there, he would know such a scheme of defence is impossible.

Personally, I think armoured trains, traction engines, and entrenching ploughs are of very doubtful utility, and, what is more, I fear that neither such things as these, nor the bravery of our soldiers, can avert the eventual loss of the Cape and Natal colonies. Such was my expressed opinion before a shot was fired, and I hold it still.

A. S. L.

[43207.]—I beg to suggest that our infantry in South Africa be supplied with steel shields of sufficient thickness to stop a rifle bullet. These shields could be used to form breastworks or temporary shelters behind which our men would be perfectly safe from rifle-bullets. If every man, when assulting the enemy's position, carried one of these shields, our troops would be able to get close up to the trenches without serious loss of life. In the Peninsular War our men would rush up to an enemy's position with sandbags and form temporary shelters, but we never hear of our men in Africa doing anything of this kind.

The shields could have spikes at the bottom corners for sticking into the ground when it was necessary to use them as stationary breastworks, and they would have two handles at each side, and then they would be very useful as temporary stretchers. The size of the shields carried by the front row of soldiers might be about 5ft. by 2½ft., and, if necessary, two men could carry the front shield,

The size of the other shields might be about 4ft. by 2½ft., as they need not be quite so large as the front row.

Steel shields would be invaluable to our men as cover, and they could stick them into the ground at any point and shoot from behind with perfect safety. Hundreds of these shields could be carried to the front in one waggon and then handed out to the men. Surely something might be done in this way to cover our men when in the open.

7, West Avenue, Derby. **W. B. Garniss.**

A HINT TO VOLUNTEERS AND OTHERS.

[43208.]—ANYONE going to the front will do well to take with him a length (say 3ft.) of small india-rubber tubing. That used for infants' feeding-bottles will do; but a stronger kind of about the same bore can be bought from dealers in rubber—an inch of glass tube should be inserted in each end, or a bit of large-bore quill. This will enable the user to get a drink from a very shallow stream or pool when there is not depth enough to dip a flask or cup in it. I have found this very useful for the purpose.

West Didsbury. **M. Cole.**

TELESCOPICAL DISCUSSIONS — TO "GEE," "HIPPALUS," ETC.

[43209.]—FROM "Ell Hay's" letter of last week (43168) it is made to appear that the substance of my letters on the Gregorian telescope has been to indicate its defects—defects which "E. H.'s" own caricature of that instrument only "fail to bring into prominence," we are told, "because it is too small." Could anything be cited as a more complete inversion of the whole substance of my Gregorian letters, or of the facts given in verification of them by other contributors, many of whom have shown a larger acquaintance with the subject than I can lay claim to?

The last reference is peculiarly interesting when read along with the letter of its author's genial and friendly opponent (42531). When I do take up the suggestion given to me in 43168, I shall not forget the *notes* to which the writer of 42531 refers. In this "Ell Hay" may feel satisfied—there need be no fear of plagiarism. **H.**

THE MOON AND THE WEATHER.

[43210.]—IT appears, from what "A. B. M." says on p. 474, that I have "rather missed" (!) the "point of the passage." I said plainly on p. 427 that I failed to see any "argument" in the passage quoted by "A. B. M.," and I see that I am not the only one who has failed. But why does not "A. B. M." point out the "point of the passage" that I have most decidedly missed—not "rather"? In these pages we have had plenty of weather prophets, from the sage of Hackney-road to the philosopher of Peckham Rye; but we have grown older, and there are now few who believe in "forecasts" of mere weather: it is important to hoist the storm-signals, even if the forecast is wrong. Many of those who work in London live, say, five miles north, some five miles south, &c., and they have compared notes to such an extent that they are convinced of the futility of attempting to predict weather for even so small a place as England. **S. R.**

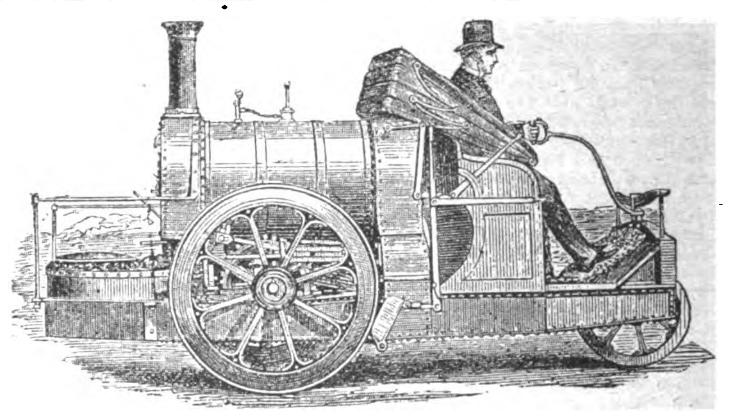
RICKETT'S ROAD LOCOMOTIVE.

[43211.]—As some of our readers are interested in motor vehicles, &c., on common roads, perhaps the inclosed cutting may be of interest. It is from the *Illustrated London News* of Sept. 15, 1860, which came into my possession recently. Hoping that it will be of use to you.

John W. Faulkner.

"RICKETT'S ROAD LOCOMOTIVE.

"Some time back we gave an illustration of a steam-carriage which was driven from Buckingham to Windsor Castle. The accompanying engraving represents a similar one, built for the Earl of Caithness, with which his lordship, accompanied by Lady Caithness, the Rev. W. Ross, and Mr. Rickett 'travelled north;' in fact, drove from Inverness to Barrogell Castle, a distance of 150 miles, virtually in two days, and which is considered the boldest and most difficult enterprise recorded in the annals of road locomotion. A trial trip to a point 150 miles ahead, with a full load of passengers and luggage, over some of the most mountainous districts of Scotland, the party for the most part unacquainted with the route, and the supplies of coal and water therefore uncertain; sometimes ascending hills of 1 in 7, towering up to a splendid sea view, and again descending the winding roads cut in the hill sides, crossing the mountain gorges at an acute angle by a narrow bridge, down an unprotected gallery of rocks, without the slightest accident or danger, certainly speaks well for the noble conductor, and also for the inventor of the carriage. It is stated that his lordship travelled the first stage from Inverness to Beauly, a distance of 14 miles, in one hour and twenty minutes, notwithstanding



frequent stoppages for horses and once for water. After leaving Beauly, on those parts of the road where some distance forward could be seen, he attained a speed of 18 miles an hour, and could have kept it up for any distance with ease and safety. He drove up the hills without difficulty, and, proceeding down the very steep declivity near where the road joins the other from Tain, the control his lordship had over it was most satisfactory, and enabled him to descend at any rate he pleased with perfect ease and safety.

"On the Monday he started from Golspie at an early hour, numbers assembling to see if it would manage the steep ascent leading to Dunrobin Castle; but, as usual, drove right on, amidst hearty cheers, to the town of Helmsdale, about 15 miles, when, on stopping for water, egress from the carriage was almost impossible from the crowd of Gaelic fishermen assembled. The town is situated at the foot of 'the Ord of Caithness,' a noted mountain, which, it was said, would bring the engine to a stand if anything could; and oft was the cry repeated, 'Ye'll ne'er get o'er the Ord!' The ascent commences immediately on leaving the town with an incline of about 1 in 10, and continues for five miles frequently 1 in 7. Winding up the precipitous route, the deep, strong, but regular beat of the engine told that, though severely taxed, the task was not more than it could manage, and without once stopping or flagging it reached the summit, when the party congratulated themselves on the crisis of the enterprise being so satisfactorily passed. For the descent into Berridale Glen his lordship had provided a special drag, but found that, with the party walking down, the ordinary screw-brakes were quite sufficient to keep it perfectly under control.

"At Wick, about seventeen miles from his lordship's residence, the arrival of the carriage was anxiously expected. Horsemen went out to meet it, and the firing of cannon announced its approach. The whole town appeared to have turned out, for the streets were thronged, and, being situated a hundred miles and more from any railway, steam on the highroads was hailed with enthusiasm. His lordship stopped more than an hour for refreshment, and then, amid the gathering shades of night, drove on to Barrogell; but the nights are not dark in that treeless county, and his lordship drove as merrily as by daylight to within a few miles of John o' Groat's.

"These carriages are designed by Mr. Rickett to carry three persons at 10 miles per hour on any ordinary roads, which they appear satisfactorily to accomplish. They require about the same space as a horse and chaise, carry sufficient water for 10 to 15 miles, and coal for 30 miles, weight 30cwt., and are well mounted on springs, the only noise being that of the escaping steam, which can be stopped instantly when horses appear frightened. The arrangement is such that the carriage and the engine are distinct, and the duties pertaining to each divided. The fireman keeps up the supply of power by attention to the fire and water, while the person occupying the front right-hand seat turns it on as he thinks proper, having absolute control in the use of the steam and in guiding the carriage.

"In the engraving the splashers are taken off the wheels in order to show the machinery, which when working is protected from dust and dirt.

MOTOR-CAR.

[43212.]—I HAVE read with much interest the first article on a small motor-car in the ENGLISH MECHANIC of Jan. 5. As one who has had a car for some time, may I venture to make one or two criticisms on the general design?

(1) The flat cords so largely employed will not, I fear, be satisfactory. In my case they are used for three purposes, one of which is to move the throttle-valve, which is opened by pulling out a stop, and is closed by the pull of a spring when the stop is pushed in. I find that the constant bending round the pulleys breaks first one strand and then another, till at last the cable breaks in the road, much to the inconvenience of the driver. If this is so, it will be worse in the hard work given to it by the writer of the articles.

Then the spring tension of jockey pulley will, I fancy, give a lot of extra friction on the belts. Mine has a fixed pull by a lever with many notches, and I find that, after starting, the pull on the jockey is very much decreased, as the belt with the slack side at the top tends to wrap itself round the pulleys, and so takes the weight off the jockey; but with a spring-tension, the weight of the drive would have to be added to the constant spring-pressure.

Again, much more slack will have to be allowed for, or there will be great loss of power when on the top speed, and I do not think a 3in. belt will answer, as, when on the top speed, the low-speed belt will, of course, be driven by countershaft over pulley or engine-shaft at considerable speed; and even with a much narrower and slacker belt I have found this absorb a considerable amount of power in slipping friction.

I am sorry to see the writer falling into the common fault of providing such a small chain-pinion on countershaft, as the acute bending angle of the chain as it passes over this causes much noise and very rapid wear to the chain; he might double both wheels with advantage, and follow the good lead of all the French racing cars.

Then as to steering, a chain is not reliable for this purpose; and I am sure a pinion and two racks will be found better and safer practice.

These few remarks are based on the actual experience of an owner of a car, who has been through the mill of practical work; and before setting out to make a car, I would advise the amateur to satisfy himself that an actual car has been made to the drawings, and is giving good results. So much depends on dimensions, which, in spite of calculations, can only be found by actual use.

I am only an amateur, and in no way interested financially in the manufacture of motor-cars.

Country House.

DIAGRAMS OF LOCOMOTIVES AT THE SOUTH KENSINGTON MUSEUM.

[43213.]—THE authorities of the South Kensington Museum have placed in position the first six of the long series of the intended locomotive diagrams. The illustrations are all drawn showing the left-hand side of the engine, and the scale throughout is ½in. to the foot, as follows:—

Liverpool and Manchester Railway. — Eight engines, built 1830 to 1834.

Leicester and Swannington Railway.— Eight engines, built 1832 to 1839.

Great Western Railway.—Seven engines, built 1837 to 1855.

Robert Stephenson and Co.—Ten engines, built 1825 to 1851.

Charles Tayleur and Co., Vulcan Foundry.—Ten engines, built 1833 to 1853.

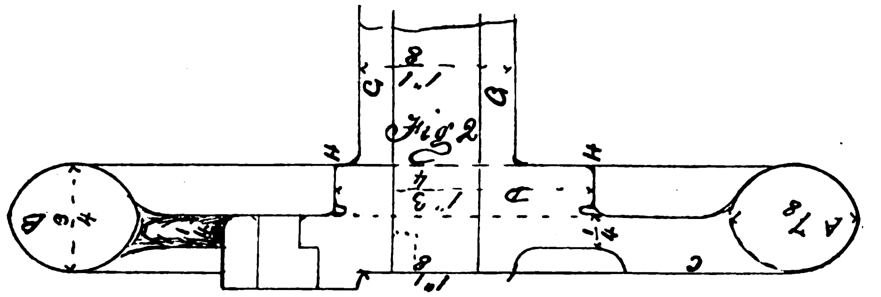
Edward Bury and Co.—Ten engines, built 1830 to 1849.

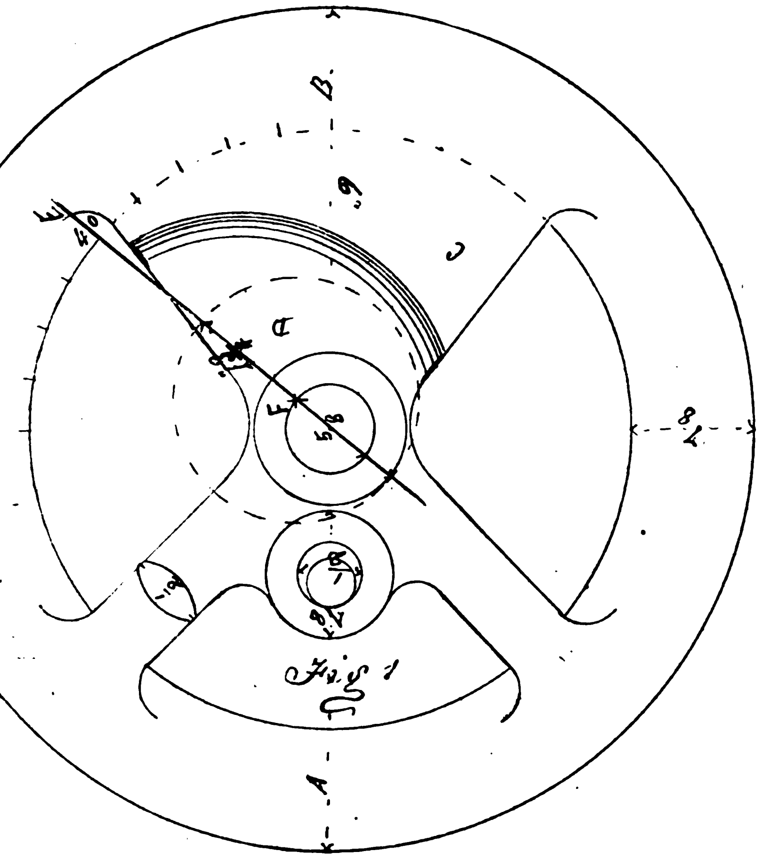
Thus the six diagrams give 53 illustrations.

One of the most interesting engines on the lists, to my mind, is the Dreadnought, of 1830, having coupled wheels and an intermediate crank-shaft; but in a short time, when it is said the Stockton and Darlington diagram will be framed, that must be of especial interest. **Observer.**

HOW TO BUILD A LIGHT ENGINE FOR VARIOUS PURPOSES.—III.

[43214.]—THIS is a front view of the flywheel, Fig. 1, with boss for crank eccentric and balance-weight cast in one. This is designed for the bracket engine, the boss upon the back side, G G, being an elongated bearing, as it is run on a pin; but when wanted for the others, is not continued farther than H H, so that I am killing two birds with one stone. The section, Fig. 2, is through A B, and letters refer to the same parts in each. C is the balance-weight,





and it can be tried with the connecting-rod, and if found too heavy, a hole can be drilled in its thickest section. D is the eccentric, E being the angle for setting out, and F the centre. Dimensions are given for all parts; but, if you think proper, you can augment your diameter, all other things being the same, unless you require a longer stroke; then, of course, you will want other things altered. But if you have made provision in your entablature for a larger diameter flywheel, still retaining your stroke, you can augment your power by having a larger diameter cylinder, and of piston to fit, all other things being the same—i.e., if you, in the first instance, make cylinder-seat upon bracket large enough, and clearance under for flywheel. I mention this that you may make this large enough in the first onset that you may at a trifling expense augment your power. The old gear will be always saleable. This is worthy of consideration all round.

Jack of All Trades.

SODOM DESTROYED BY THE LEONIDS.

[43215.]—THESE are the last few lines that I can spare for Mr. Garbett. He first appeared with a coarse personal epithet and allusions to Lyell and Darwin, which I noted, and with crass assertiveness he drifts into Bible legends. These are beyond the pale of exact modern science, and are not to be discussed therewith. The student of geology truthfully studying facts from the stone-leaves or stratifications of the earth's crust, acquires a knowledge of its formation during immense epochs of time; he gains no true information from ancient Scripture legends, and has to ignore them. So, also, must these be repudiated by the disciples of the tangible science of evolution from primitive forms of organic life to more advanced beings gifted with instinct or mind by the influence of surroundings. As yet we know nothing of the relation of mind to matter. This we may hope for.

Instead of shifting the supposed site of the City of Sodom north or south, to avoid a local difficulty, the very mechanical manner of its alleged destruction should decide the point. As a small illustration, a boy might fling stones over a hollow to destroy objectionable living things therein; but if the operation were performed on a Dead-Sea scale, the result would be apparent for evermore.

Mr. Garbett winds up by asking why "Gossip" or myself should not go and examine the alleged remains of Noah's Ark? Simply because I did not believe that this vessel ever existed. There are still millions that do so. Let them raise a small subscription for the search, with Mr. Garbett at the fore. If, instead of finding a few small decayed beams, they should discover the remains of a colossal vessel of enormous proportions, such as man had never before seen, their triumph would be a grand one.

F. H. Wenham.

IS THE THEORY OF GRAVITATION A FINALITY?

[42216.]—I DO not know on what authority your correspondent, Mr. Hugh Alexander (letter 43152), remarks that it is not true to say that *all* the celestial motions are explained by gravitation. True, we cannot explain by gravitation the rotation of the sun on its axis, and that of the earth and planets; but that is only owing to our inferior knowledge about gravitation. If one said to a person who knew nothing whatever about *universal* gravitation, that the same force which urges a stone to the earth also keeps the planets in their orbits round the sun, he would immediately answer, "How?" "Why?" This he would say because the bare statement of the fact is not self-evident; but we know that it can explain the revolutions of the planets, though we are not *yet* able to explain their rotations on their axes by gravitation, which statement does not assert that we shall *never* be able to explain their motions by gravity. As regards the velocity of the moon, I always thought that the moon did move faster when in conjunction than when in opposition, and as for the tides, they are thoroughly explained by gravitation. The reason why the moon generates tides simultaneously at the antipodes is simply that the moon pulls the earth, being nearer, away from the water on the opposite side of the earth to the moon. Your correspondent goes on to say, "The accuracy with which astronomers are able to predict the tides and eclipses is sometimes very improperly attributed to the theory of gravitation." Now the great law of periodicity comes from gravitation, and therefore we use this law of periodicity to calculate eclipses; but we cannot use this law to calculate perturbations. Gravity can explain every perturbation of the moon—and if it can do that, it can explain all the motions of all the celestial bodies—so accurately, that it seems to me absurd to take away that which explains everything, or, at least, may in time be shown to explain everything, and to place in its stead that which explains half. Up to the present we have never met with anything in the celestial bodies that violates the laws of gravitation; why, then, not let it continue? Gravitation, moreover, has nothing whatever to do with physical appearances, nor would the physical appearance of a body alter its attractive force on another body. But if the attractive force of the sun were to change, it might alter the physical appearance of the planets; for instance, if the sun were to pull the planets with a force about 1,000 times as strong as it is now, the physical appearance of the planets might then change from beautiful scenery into dripping. Gravity cannot in any way be related to magnetism, for magnetic attraction is only produced on certain bodies, while the attraction of gravitation is produced on all bodies. Your correspondent in the first sentence says, that mathematicians tell us that "all the celestial motions are explained by the one *law of universal gravitation.*" The italics are mine. Now a stone does not fall to the earth on account of the law of gravitation, nor does its gravity or weight explain why it falls. The laws of nature cannot be the causes of nature. It is often said that gravitation is attraction, and that bodies fall to the earth because the earth attracts them. Now the word "attract" simply means to "draw towards," and to say, when two bodies move towards one another, that they are "drawn towards" one another, is simply to describe the fact, and certainly cannot make us any wiser than we were before. Gravity must exist; but what it is we do not know. It may be a form of electricity, or of some other force; but gravity there must be. The law of gravitation simply states what will happen under certain circumstances. If the theory of gravitation is not a finality, it certainly is not even an initiality.

N. M. Munro.

AIR-SHIP OR AEROPLANE.

[43217.]—I NOTE Mr. Challis remarks that the future of aërial navigation—that is, the capability of travelling in the air rapidly in any direction desired—rests with the use of an extension of wings or aëroplanes, and not with inflated gas vessels.

It is well known that in the year 1856 I made three full-sized arrangements of separated aëroplanes somewhat differing in form, each capable of sustaining the weight of a man, but they all failed for want of equilibrium. This was the weak point in the machines of Lilienthal and Pilcher, whose experiments ended fatally. These performed gliding flights to an extent of near 100 yards; but the only motive force was that from the impulse given at the first start. The whole attention of the occupant of the machine was absorbed in balancing the arrangement during flight—he can do nothing else.

If, instead of wastefully consuming the power due from elevation as a descent from altitude, he could have used his own personal strength for forward propulsion, he would have prolonged his flight considerably—how far no one can state; but this would be the next step in advance, and have given some important data.

I cannot see why we should arrogate to ourselves as Britons the sole ability for success when other nations, and particularly Americans, are working in the same direction with unrivalled mechanical skill.

F. H. Wenham.

ERRATUM.—In letter 43173, p. 473, "Where is the Image Formed?" beginning of twenty-fifth line, for "other," read "ether."

C. A. Naylor.

THE Chicago, Burlington, and Quincy Railroad is putting electric headlights on some of the locomotives used on the fast mail and the Denver limited trains.

THE expedition of Baron Toll, organised for the exploration of the New Siberia Islands and Sannikoff Land, will set out in June next from a Norwegian port, whence it will proceed to the mouth of the Lena, on the banks of which, at a point above the town of Yakutak, it will pass the winter. During the summer of 1901 the expedition will begin its explorations towards the North, picking up *en route* a detachment which will be sent forward from the main body during March, with a sufficient supply of dogs.

REPLIES TO QUERIES.

⁂ *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[96784.]—**Grate Front.**—Querist wants to make a pattern for a set of bars for register grate. Well, why not do so? It is simple enough if he is able to shape a piece of wood; if not, get one made, or else make the whole of wrought iron. The holes can be drilled, as there is no reason why holes in bottom bar should not go right through; nor is it necessary to screw bars in. Make the two horizontal bars about 1in. by ⅜in., the vertical bars about $\frac{5}{16}$in. Round, shoulder one end down to drop in bottom bar, which must have smaller holes than the top one. A. R.

[96951.] — **Inflammation of the Parotid Glands.**—Try (1) painting the glands with tincture of iodine every night until inflammation warns you to stop; (2) ointment of the biniodide of mercury; a little rubbed in every night sitting before the fire. Constitution must be kept up with exercise, good feeding, and tonics, if necessary.

Galway. M. B.

[97069.] — **Formula (U.Q.)** — In reply to "Glatton," my query to be arranged algebraically may be put: How much of a salt containing 5 per cent. chlorine, must be added, say, to ten gallons of water, to make it contain 2 per cent. chlorine? The water contains ½ per cent. of chlorine before the salt is added. My query should have read—line 5—"to make it contain so much per cent?" BAZIN.

[97157.]—**Silver-Plating Aluminium.**—Why is it desired to silver-plate aluminium forks and spoons? It can be done, but *cui bono?* The metal aluminium is very light, but I think it is liable to deterioration when used in the ordinary way as forks and spoons, which sometimes come into contact with vinegar and often with salt. The "advantage" of electro-plating aluminium is, I think, an unknown quantity. M. T.

[97159.]—**Piano-Strings.**—The work is done in a sort of "lathe," which is really only a wire-winding machine. Rig up anything that will turn a wire round, and then supply the covering wire by hand, or automatically from a reel. T. P.

[97160.]—**Automatic American Organ.**—If "Tuner" can refer to the back volumes of this paper—say, from 1883 to 1893—he will find about all there is to learn in connection with the "automatic" American organs. Several correspondents (Mr. Wenham, "A. S. L.," and others) had something to say, and if there is anything further or new, perhaps some reader will give it. The "motor" was a hand-crank; but, of course, clockwork might be used. C. KERR.

[97161.]—**Ship's Surveyor.**—As the querist asks for information as to the exam. under the Board of Trade, why does he not apply to that department? He can obtain all requisite information on application. If he wants to know how to become a surveyor for Lloyd's, he must apply to the secretary of that institution, White Lion-court, Cornhill, E.C. I have an idea that they want people who do not require to ask for information. A 1.

[97164.]—**Zinc Connection.**—See many replies in back volumes for hints, and if necessary repeat the query with fuller details. Wires can be screwed into zinc plates, and be protected with varnish; but it is useless guessing without details. Many plans have been given in previous numbers, and also in Mr. Sprague's work and other textbooks of practical electricity. J. M.

[97174.]—**Water-Power.**—Tables are published which give the power to be obtained from water at different "heads." It will be necessary for the querist to ascertain the "quantity" of water flowing through the 6in. pipe. Does he mean that the pipe is full? METOPS.

[97180.]—**Marine Navigation.**—The statement is one of many which creep into the newspapers of to-day. If four knots can be obtained with the exhaust steam from the auxiliaries, what a waste of steam there must be on the auxiliaries! I should think the statement is simply "rot." I have not yet discovered how to get something out of nothing, and I don't believe anyone else has. I suppose the author of the statement has been told that there is much waste in "auxiliaries"—as there is, very likely; but the exhaust from them will not run the engines of a liner. G. S. N.

[97257.]—**Coherer and Alternator.**—To MR. BOTTONE.—An alternator built as you suggest will answer nicely. There will be practically no advantage in increasing the number of pole pieces; two will be quite sufficient. Let these together embrace two-thirds of the armature. As you do not state the depth of the ring, but its diameter only, I am unable to give you any very exact directions as to the gauge of wire to use for winding; roughly, if your armature is 7in. diameter and 6in. deep, you will require about 6lb. No. 20 on it; the fields will take about 25lb. No. 16. At a speed of about 1,200 revs. per minute such an alternator should give about 2 ampères at 220 volts pressure. This would give you about 40 alternations per second. If you want quicker, you must increase the number of poles in pairs; four poles give 80, and 8 poles 160 per second, &c. S. BOTTONE.

[97256.]—**Windmills.**—If "Alternator" will refer to the description in *Engineering* to which I referred him, he will see that the particular size I gave has been experimented on successfully; I have also tried this size and found it answer the purpose of preventing false readings of pressure due to eddies in the current of air. If air blows across a tube (Fig. 1), there is a reduction of pressure behind

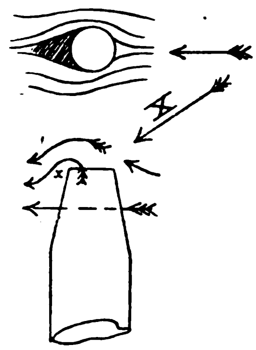


FIG. 1.

it in the position shown by cross-hatching. Air tends to flow into this partial vacuum from the nearest sources, one being the end of the tube as shown by arrows. On this account apparent vacua in a manometer may result from velocity only. In the same way currents such as X (Fig. 1) would show an apparent increase of pressure; the real pressure remaining unaltered. In Fig. 2 I have

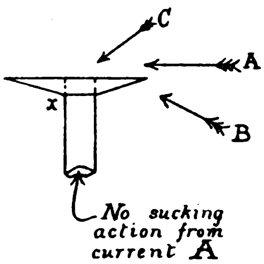

FIG. 2.

sketched a wooden disc with thin edge on the end of a manometer tube. Here the partial vacuum is found at *r* as before; but the end of the tube is shielded from it, and the reading of the manometer registers the true pressure of a current, A. A current B would, however, show an apparent reduction of pressure, and C would give an indication of increased pressure. These errors are eliminated by the wire-gauze sandwich shown on p. 431. The combination with a "pilot" tube, as suggested by me, does not appear in the original description. GLATTON.

[97284.]—**Geometrical Progression.**—We are told that "any biquadratic with numerical coefficients can easily be broken up into quadratic factors by anyone who is able to solve a cubic." This is misleading, for it means that the orthodox method of solving a biquadratic includes its resolution into quadratic factors, whereas the object aimed at has been direct resolution without recourse to cubics. For instance, how can we solve

$$x^4 + 12x^3 + 55x^2 + 113x + 87 = 0$$

by direct factorisation? Factorisation is the crux of equations, and it should be sufficiently clear that no equation of odd degree can be resolved into quadratic factors. For instance, a quintic, if directly resolvable, must consist of linear, linear and quadratic, or quadratic and cubic factors. To maintain that the roots of an equation may be expressed as so many linear factors or simple equations does not assist us in finding them. "Quivis" approves of "guessing" as a mode of factorisation; but, like some others, objects to assumption when made by anyone except himself. Referring to the G. P. in question, I never affirmed that $r = x$, but simply employed that postulate to show that under some circumstances a biquadratic might be solved by means of a simple equation, and that by a necessary property of G P. a second solution was virtually included without reference to quadratics of all. Thus the result $r = x$, which satisfies the problem, includes another—viz., $r^5 x$ = first term, and $\frac{1}{r}$ = rates. Although "C. P." employs a formula which "Quivis" thinks would be adopted by "every experienced mathematician," yet the original querist could not have been expected to know it, and "C. P." did not enlighten him as to its derivation. "Quivis" shows unfairness in appropriating my remarks *re* "A. O. S.'s" solution as his own; also in accepting the assumption that a r may be treated as integers in the indeterminate equation $a + 20r = 42$, while ridiculing the idea in "Ontario's" latest example. He should have reserved his irony for the latter, who made the assumption, and not for one who did not. And here "Quivis" reveals great illogicality, for he says my argument is worthless when "it states that r being integral and equal to $\frac{315 - x}{150 + x}$, which is equal to $2 + \frac{15 - 3x}{150 + x}$, then r is necessarily 2." I certainly do assert this, since for all positive values of x this second term must be a fraction, except it be o, and by the assumption r cannot be the former; whence it must be the latter. But "Quivis" goes on: "Please observe that the *same argument* shows that r being equal to $\frac{315 - x}{150 + x}$, which is equal to $-1 + \frac{465}{150 + x}$ must necessarily be -1, or, better still, r being equal to the fraction $\frac{315 - x}{150 + x}$ must necessarily be zero." Thus "Quivis" allows his bias to overrule his discretion, for (1) no assumption of a negative integer was made; (2) if it had been, we could not make $\frac{465}{150 + x} = o$; and as fractional values are excluded, we are limited at last to $x = 5$, which shows the error made by taking -1 for the quotient instead of $-1 + \frac{465}{150 + 5}$ $= -1 + 3 = 2$ as before. But since "Quivis's" own solution gives one value of $r = -1$, it is strange he should now scout this result, even although he obtains it by inconsequential reasoning. I must dissent from the final clause, since I cannot admit that any quintic can be expressed by quadratic factors. Leaving controversy, we may notice an interesting anomaly. If we take each equation singly, we get x expressed by five values of r, whereas if we subtract the second equation from the first we obtain an indeterminable involving four values only—viz.,

$$x(r + r^2 + r^3 + r^4) = 150.$$

But when x is found, only four values of r satisfy the problem, so that the equation is not a pure quintic, but a disguised biquadratic, by reason of the common factor $(r + 1)$, which should be eliminated. In conclusion, it may be shown that if a direct method of solving biquadratics were discovered, it would enable us to solve cubics without any resort to Cardan's formula.

West Norwood, Jan. 6. HENRY T. BURGESS.

[97284.]—**Geometrical Progression.**—If we limit the question to integral values for x and r, the simplest method appears to be obtained thus: We have—

$$x(1 + r^5) = 315 - 150 = 165.$$

Therefore— $$r^5 + \frac{165}{x} - 1.$$

Now, since x is an integer, the right-hand side cannot exceed 164 (which is less than 3^5). Hence r cannot exceed 2. Now $r = 1$ gives—

$$x = \frac{165}{2}$$

which is fractional, and $r = 2$ gives—

$$x = \frac{165}{33} = 5.$$

Hence the series 5, 10, 20, 40, 80, 160. If worked in a strictly formal way we get an easily solved biquadratic. (I do not understand how Mr. Burgess obtains a quintic.) We have—

$$x \cdot \frac{r^6 - 1}{r - 1} 315,$$

and— $$r \cdot x \cdot \frac{r^4 - 1}{r - 1} = 150.$$

By division—

$$\frac{r^4 + r^2 + 1}{r(r^2 + 1)} = \frac{315}{150} = \frac{21}{10}$$

Therefore— $$\frac{(r^2 + 1)^2 - r^2}{r(r^2 + 1)} = \frac{21}{10}$$

$$\frac{r^2 + 1}{r} - \frac{r}{r^2 + 1} = \frac{21}{10} \text{ (of the form } y - \frac{1}{y} = a\text{).}$$

This quadratic gives—

$$\frac{r^2 + 1}{r} = \frac{5}{2} \text{ and } -\frac{2}{5}$$

The first root leads to—

$$r = 2, \text{ and } \tfrac{1}{2},$$

which give for x the values 5 and 160 respectively.

The other root leads to impossible values from x and r. A. O. S.

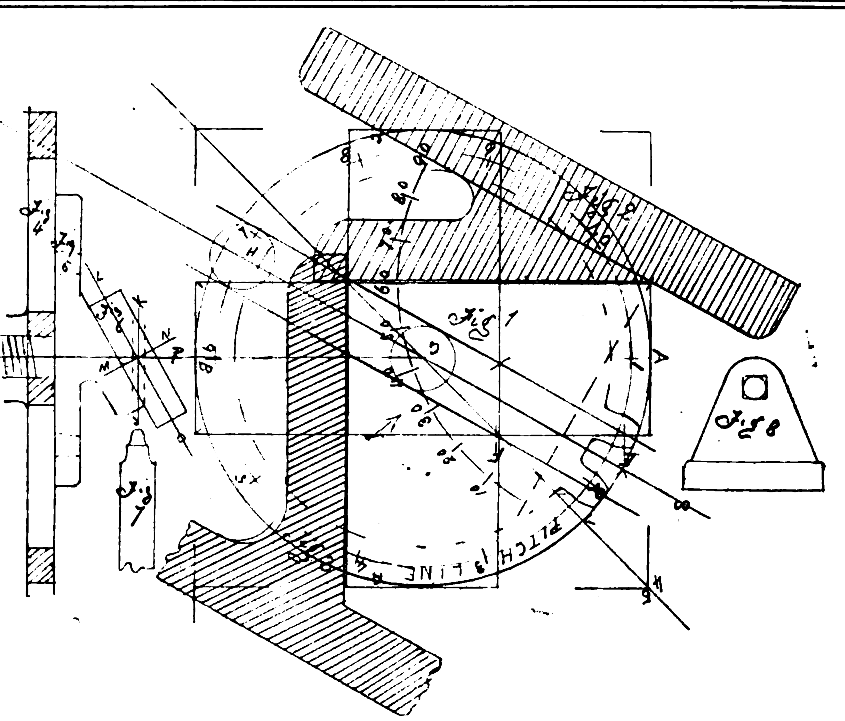
[97284.]—**Geometrical Progression.**—CORRECTION.—In my reply (p. 476), in the expression $\frac{4,265}{243}$ denoting the sum of the six terms, the figures 6 and 5 should change places.
Bath. M.I.C.E.

[97300.]—**Gas v. Petroleum.**—With reference to your correspondent's inquiry in your Dec. 22 number re Gas v. Petroleum, we beg to say that the comparative heating power is in the proportion of 1lb. of oil equals 20c.ft. of ordinary coal-gas.
FLETCHER, RUSSELL, AND CO., LTD.

[97308.]—**Soda and Uric Acid.**—Most of the readers of "Ours" must imagine by this time that uric acid is at the root of all the ills that flesh is heir to—a doctrine so confidently held by a lady who passed through these pages like a brilliant medical meteor some time ago. As a matter of fact, there is probably only one disease caused by uric acid, and that is gout, over-production of this poison being the product, and not the cause of "Bright's disease, &c." As so many correspondents seem to be interested in this question, perhaps I may quote the following:—In the metabolism of the healthy body uric acid and the neutral and acid urates play a very minor part. They are in the form, in reality, of a quadriurate, which, unlike the biurate, is easily soluble in the blood-serum, and it is in this form that the uric acid circulates in the blood, and is excreted by the kidneys. In perfect health the elimination of the quadriurate proceeds with sufficient speed and completeness to prevent any undue detention, or any accumulation of it in the blood; but in the gouty state this process is interrupted, either from deficient action of the kidneys, or from excessive introduction of urates into the circulation, or from some other cause, and the quadriurate lingers unduly in the blood, and accumulates therein. The detained quadriurate, circulating in a medium which is rich in sodium carbonate, gradually takes up an additional atom of base, and is thereby transformed into biurate. This transformation alters the physiological problem. The uric acid—or, rather, a portion of it—circulates no longer as the more soluble and presumably easily-secreted quadriurate, but as biurate, which is less soluble, and probably also, either for that reason or because it is a compound foreign to the normal economy, less easy of removal by the kidneys. The biurate thus produced exists at first in the gelatinous modifications, but with the lapse of time and increasing accumulation it passes on into the almost insoluble crystalline condition, and then precipitation becomes imminent, or actually takes place. The precipitation is particularly apt to occur in certain parts of the body where the circulation is feeble and the temperature low, and in regions where the lymph contains a relatively high percentage of sodium chloride (common salt), as in the synovial sheaths.
Galway. M. B.

[97308.]—**Soda and Uric Acid.**—In reply to "D. W. A." (p. 477), I was not troubled with headache, so do not know if lithia would affect it. If may interest him to know that I had a recurrence of hip-stiffness a few weeks ago, but the lithia cured it in one day; or, perhaps, I should say it had gone after taking the medicine for one day. "D. W. A." has, I presume, gone to a doctor first, and given him a chance of treating him before experimenting with lithia. Uric acid accumulations are not to be treated lightly. GLATTON.

[97318.]—**To "Jack of All Trades."**—Well, I have managed to crowd a lot of information in a small space, and if you cannot see your way after my making wheels, discs, setting out pitching, making angle-plates, and chucking the wheel for you for 10 teeth, and making tool—in fact, doing all but cutting of them for you—at which I draw the line—what must I say? Why, that you are nowhere as a mechanic. If you refer to sketch, you will find A, B, C, D; those letters represent the edge of wheel-discs, the same placed at right-angles to one another; where the line through the top angle and bottom of square is drawn represents angle 45°. If the wheels were cut at that they would have the same number of teeth, and, consequently, go the same speed. Now your discs work out to a pitch of $\frac{1}{8}$, $\frac{3}{32}$, or thereabouts: near enough for wheel-cutting. Now, just drop a pitch as shown at the top of E; draw a line through the centre where you will find G, and another, H, circles of pitches diameters; there you have the path of the cutter to do what you require. Take the pitch of that right and left, and draw a parallel line by the circles; this gives you the centres E and F where they cross the face of wheel-disc. Now, if you set your compasses to these centres, you will find by stepping it around the pitch-line, as shown from 1 to 10, i.e., 10 teeth. Now, on the other disc the angles are different. Refer to the disc C D, now refer to F, and directly below you will find another centre; now, if lined out accurately, take those centres F and the one below upon the left face of C D, and upon stepping that around should give you 20 teeth. This is shown as in Fig. 1. Fig. 2 shows one of the angle-plates, and an arc is extended and numbered to show the angle. Now, if one wheel is cut at an angle of 60°, the next to run into it must be 30°, so that the two form a right angle; for instance, if the plates are made right—the two angles bolted together—their feet will be parallel with each other. Fig. 3 is the angle-plate for the 20-toothed wheel. Now for position in cutting of them up. Fig. 4 is section of a face-plate of a lathe showing through centre of it the two long slots that are put in them at right angles. Fig. 5 represents one of the angle-plates in position with one of the wheel discs for cutting the 10-toothed one (see Fig. 6). It is bolted upon it with a centre bolt and bush with a washer. Now you will see the lines widen, the same as large sketch described above: this is the path of the cutter. Let it be a slide-rest tool, as Fig. 7, or a milling cutter. You see that it is parallel with the chuck or face-plate. To set your discs by you must put centre lines as shown around the side and across the face, as L, M, N, O, and the centre K must be set with a scribing gauge off the face of face-plate on both sides of the disc, and the same from the lathe-bed; both sides of disc level with and in line with the centre, as shown. Fig. 8 shows you the front view of the angle-leaf of the chuck tapered away to clear your tool. Now you must not go right round with your lathe, or you will make a mess of it. Don't forget that I mentioned this, and say I have spoiled your discs. Cut only one side of your wheel—the same as cutting a screw. You had better square under the head of your holding-down bolt, as shown at Fig. 7. Be particular about fitting your job. When once your cutter is set, do not shift it until your job is finished. Your wheel will want dividing out for 10 and 20. The same cutter does for either. Screw wheels are not new—they were originally invented by the Swiss for the Swiss mandrel for watchmaking, to take up back-lash. JACK OF ALL TRADES.

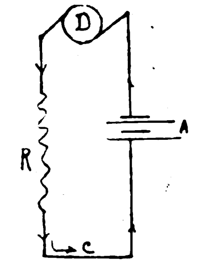


[97319.]—**Belts.**—"Why does an ordinary belt last a very short time?" If it had its due, it ought to last for years, even if it has such short centres and a great strain. I have seen a belt, working exactly the same way, driving a very heavy planing machine, and it lasted for three or four years, and then it was removed to another place. Now, we have a similar case in our shop again, the only difference being longer centres—about 15ft., I think it is—whereas the case before was only 5ft. centres. In our second case, we had a little trouble with the belt stretching such a great deal, but now it is going on famously. "Anyhow, what does W. Moore call a short time, and what's the matter with the belt? Does it break, or what?" I, myself, would think that a rope belting would be worse. APEX.

[97324.]—**Gas-Engine.**—So far as I remember, "Mousetrap's" engine is of the same make as mine. Strange to say, I also had a new crank put in, which had $\frac{1}{16}$in. larger throw than the old one, but it made no difference. The tremendous explosion which you mention is no doubt caused by charge firing before the end of stroke. As for the exhaust going off like a gun, this is probably caused by an accumulation of unburnt gas in exhaust-pipe which explodes when engine exhausts a charge which has fired, and which is still at a high temperature. I have tried inlet spring at various strengths, and find that for high speeds (above 300) it should be strengthened slightly to permit of its working quickly. Your exhaust-valve is probably all right; mine has only $\frac{1}{16}$in. lift, and that is enough. "Mousetrap's" experiences are exactly similar to mine of a year ago, and I must admit that the cause of all the trouble was the ignition tube. My advice is: Keep it hot enough and in the right place, and you'll have little more trouble. Engine shouldn't require to be turned 30 revolutions before firing; it should fire after the first compression. See that your exhaust takes place at the proper time. W. EWART GIBSON.
103, Ferry-road, Leith, N.B.

[97324.]—**Gas-Engine.**—I should hardly think that the new crank would have anything to do with the fault; but, anyhow, "Mousetrap" should look to the other details of his engine first. He should grind his valves in afresh with powdered emery, and see that they are properly down on the seat when fixed in their place. Then the ignition-tube wants looking to. See that the small hole leading to cylinder is quite clear. The spring on the inlet-valve can be tightened a little; and if there is a spring on the outlet-valve, that can be tightened as well. If the exhaust is as sharp as it was when it was running all right, it shouldn't be interfered with. The exhaust should be looked to, and also the air-pipe, to see that they are all clear. If "Mousetrap" finds that everything is all right as described, and it still won't work satisfactorily, he ought to get a man to look at it, and examine properly, for in my experience I have always had to look for the fault, and remedy accordingly.
APEX.

[97339.]—**Accumulators.**—If charging, current



required is 2 amps., R = 20w. If current required is 4 amps., R = 10w., &c. H. L.

[97343.]—**Influence Machine.**—If your plate machine has plates of the ordinary thick glass (nearly $\frac{3}{8}$in. thick) it will hardly be advisable to convert it into a Wimshurst, as the thickness of the glass will militate against its efficiency. If, however, the plates do not exceed $\frac{1}{8}$in. you can convert it into a good influence machine, if built on the lines directed in my book "Radiography." If well made, such a machine will easily give a 7in. spark.
S. BOTTONE.

[97345.]—**Wax Phonograph Records.**—To answer all your queries would take up too much space. I should advise you to get "The Phonograph, and How to Construct It," by the late

W. Gillett. It gives very clear instructions as to making the mould, and the right sort of wax to use, &c. It is published by E. and F. N. Spon.

H. F. L.

[97346.]—**Emery Wheels.** — Turn wheels of pine wood, coat with good glue, and roll in emery-powder, heated to 200° F. Several coats may be required. Is an impure variety of corundum, or pure crystallised alumina, found in Greece (Naxos), Tyre, Smyrna, Asia Minor. The wheels also formed by mixing powdered mineral with a plastic or liquid vehicle, moulding into shape, and then causing to set in solid form. Vehicle may be shellac, artificial stone, loam and water, crystalline limestone. REGENT'S PARK.

[97348.] — **Orientation.** — Sir J. N. Lockyer, Knt., Professor of Solar Physics, has written on Orientation in Egypt, &c. See back volumes of *Nature*; also Julia B. de Forest's "Short History of Art: Roman Art," p. 88, D. M. and Co. Batsford, of High Holborn, useful man to inquire of as to works thereon. REGENT'S PARK.

[97348.]—**Orientation.**—The most notable example in the world is found in the Great Pyramid, which contains several tubes or holes through immense thicknesses of stone perfectly smooth and true, and which for a long time were supposed to be merely vent-holes, but were found to be in exact line with several of the fixed stars, and were evidently intended for astronomical purposes. For a full description read "The Great Pyramid," by Taylor, a very interesting work. MONTY.

[97349.]—**Sore Throat.**—Dr. Ruddock, in his homœopathic book, gives following: Simple soreness uncomplicated by ulceration, quinsy, or syphilis: by Acon., when throat is dry; rough and hard dry cough; and by Bell. if redness with raw sensation; by Merc, if feels swollen, glands sore, enlarged, and slight deafness; or by Nux, if stomach disordered. If you do not mind a fee, consult Dr. Epps, of Great Russell-street; or cheaper at hospital, Great Ormonde-street. Breathe through nose. REGENT'S PARK.

[97349.] — **Sore Throat and Tongue.** — As "Comus" seems to prefer homœopathy, if he will get pilules of Capsicum, and let three at a time, thrice a day, dissolve slowly in the mouth, they will, most likely, improve the state of throat. If this be not strong enough, he may get, at any chemist's, tincture of capsicum; put $1\frac{1}{2}$ drachm of it into 8oz. of infusion of roses, or even plain water, and use it as a gargle—it may have a better effect. He should also improve the general health. After influenza, I have found the tincture of kreat. more effectual than anything. Also, in all affections of the throat, such as diphtheria, quinsy, &c., I have found that a poultice of fresh yeast spread on a cloth, and applied externally on the throat from ear to ear, and renewed as it gets dry, to have the best effect. He should use this as well. W. A. A.

[97349.]—**Sore Throat and Tongue.**—You suffer from a form of aphthous stomatitis, probably following on the influenzal inflammation. (1) Get some chlorate of potash and cocaine lozenges, and suck one occasionally. (2) Use frequently a mouth-wash of glycerine of borax and rose-water, and keep your teeth very clean with a soft brush. (3) Look after your diet.

Galway. M. B.

[97350.]—**Thermo-Dynamics.** — The specific heat of a substance is the ratio between the amount of heat required to raise a given mass of the substance through a given interval of temperature, and the amount of heat required to raise an equal mass of water through an equal interval of temperature. The unit of heat is the amount required to raise 1 gramme of water through 1° C. Entropy or heat-weight hardly lends itself to a definition. But it may be defined thus.—"When a body takes in or rejects heat, it is said to change its entropy." The entropy of a body may be found from the following equations. Thus for water—

$$\phi_{\omega} = \int \frac{\delta h}{\tau} = \int_{\tau_0}^{\tau_1} \frac{\delta \tau}{\tau} = \log_{\epsilon} \frac{\tau_1}{\tau_0}$$

where ϕ = entropy,
τ_1 = final temp. (absolute),
τ_0 = initial temp. (absolute).

For any other substance this quantity is multiplied by the specific heat of that substance, and for steam it is given by the equation $\frac{L}{T}$, where L is the latent heat, and T being the temperature (absolute).

Lasswade. J. WIGHT.

[97350.] — **Thermo-Dynamics.** — Property of body expressed as mathematical quantity which remains constant when a gas or other body changes its volume or does work without any heat entering or leaving it, but which, if a small amount of heat enters or leaves the body, is increased or diminished proportionately to this amount divided by the absolute temperature, sometimes called the thermodynamic function. Since heat always flows from higher to lower temperature, a body that gains heat always gains more entropy than is lost by the body losing that heat. Hence, with every flow of heat the total entropy of a system of bodies rises, and thus tends towards a maximum. Owing to a misapprehension of the meaning of "Clausius, the inventor of the term, "entropy" has been used also to mean available energy. Thermal capacity equals quantity of heat required to raise the temperature of a body 1° Centigrade. No good dictionaries where you live, I suppose. REGENT'S PARK.

[97351.]—**Coating Cardboard Cylinders.**—Dissolve wax (say, 1lb.) in turpentine (say, 3 pints). Mixture trifle thicker than turpentine. Lay on. Dry. REGENT'S PARK.

[97352.]—**Longitude.**—Perhaps this may aid, out of "Encyclopædia Britt." Latitudes and longitudes determined by observations of stars, sun, and moon. As earth rotates, zenith of any place (not on the Equator) traces among the stars a small circle having for centre that point in which axis of rotation meets the heavens. If a star is at this last point it would be apparently motionless, having always same altitude and azimuth, &c. The position of zenith at any moment may be determined by simultaneous observation of zenith distance of two known stars. For these distances clearly determine a point in the heavens whose declination and right ascension can be computed by spherical trigonometry. Thus both time and latitude obtained suitable for travellers exploring unknown country, it is desirable that the stars should differ in azimuth by a right angle (or about). If path of zenith or latitude be known, a single observation of the zenith distance of known star towards E. or W. fixes place or right ascension of zenith at sidereal time. Here pole, zenith, and star are angular points of spherical triangle, three sides known. Angle at pole, being computed, is difference of right ascension of the star, and zenith, &c. Expectations for the longitude depend chiefly on the moon observations. Of course if you have *Nautical Almanac* you will find angular distances of moon from certain stars in its path for every three hours of Greenwich time, and by observing distance of moon from one of these stars, you can infer corresponding Greenwich time at moment of observation. Comparison of this with local time gives longitude, &c. Latitude by measures of star's zenith on the meridian duly corrected for refraction, then the polar distance being known, latitude at once ascertained. The stars should be observed in pairs of nearly equal zenith distance north and south; this eliminates errors. Time best determined by measuring zenith distance (zenith) of stars situated not far from prime vertical; then, the latitude and polar distance being known, the hour-angle P. of spherical triangle found by calculation. Time may also be determined by observing transit of stars over the wires of the telescope of a theodolite set up in the meridian. Longitude also determined by astronomical methods as by observation of moon's motion, or differentially with aid of telegraph lines and travelling chronometers. Absolute longitude is travellers' great difficulty. Observations are of various kinds: (1) Lunar distance, (2) lunar zenith distance, (3) lunar transits over meridian, (4) lunar occultation of stars, (5) eclipses sun and moon, (6) eclipses Jupiter's Satellites. (1) and (3) helped by the *Nautical Almanac*. First requires sextant or other reflecting instrument; (2) may be done with ditto, or a theodolite; (3) with a theodolite. The last three require good astronomical telescope. First requires three observers—one to take lunar distance, the other two to measure zenith distance of moon and star; but as last two are not wanted with great accuracy, the several observations may be taken in succession by same person, and observed zenith distance afterwards adjusted to time of lunar distance. Effects of errors of observations in these methods:—In (1) error in time produces same error in longitude; in (2), error of 1sec. produces at least 30sec. of time in longitude and 1sec. of arc; in zenith distance, at least 2sec. of time in longitude; in (3) to (6), error of time produces same error in longitude. First method preferred by those more used to the sextant; second method by those with theodolite of good telescopic power, and gives very good results when observations are made at most favourable time, or when resultant of moon's motion is in Right Ascension, and in declination lies in the direction of observer's zenith. REGENT'S PARK.

[97353.]—**Altitude.**—Sometimes convenient in topographical and levelling operations, to apply small corrections to observations of height for curvature and refraction simultaneously. Putting d for distance, r for earth's radius, K for coefficient of refraction and expressing distance and radius in miles, and the correction to height in feet. Then correction for curvature $= \frac{2}{3} d^2$; correction for refraction $= \frac{4}{3} \mathrm{K}\, d^2$; correction for both $= \frac{2 - 4\mathrm{K}}{3} d^2$.

Errors are liable, and accumulate, though too minute to attract notice at any single station, as when work is carried on under uniformly sinking or rising refraction, from morning to midday or from midday to evening, or when instrument takes some time to settle on its bearings after being set up for for observation. May be eliminated by (1) alternating order of observation of staves, taking back-staff first at one station and forward first at next. (2) By working in a circuit, or returning over same line back to the origin. (3) By dividing a line into sections, and reversing direction of operation in alternate sections. Cumulative error, not eliminable by working in a circuit, may be caused when there is much northing or southing in direction of line, for then the sun's light will fall endwise on bubble of level, illuminating outer edge of rim at nearer end and inner edge at outer edge, and so biassing observer to take scale readings of edges which are not equidistant from centre of bubble. This introduces tendency to raise south, or depress north, ends of lines of level in the Northern Hemisphere. You may be able to compare these points with your own, and see which are best. REGENT'S PARK.

[97355.]—**Mercury Interrupter.**—The glass tube is drawn out into a fine point, like a sharpened pencil, by pulling out over the flame of a gas-jet or spirit lamp. The extreme tip of this point is then broken off, the platinum wire inserted, leaving as much projecting as desired, when finally the glass is melted round the platinum wire, to which it will adhere easily, by holding over the flame of a spirit lamp, &c. S. BOTTONE.

[97355.]—**Mercury Interrupter.**—The platinum requires no "attaching" to the glass. The tube is fused round the platinum wire, and holds it by the extreme closeness of the fit.

A. H. AVERY, A.Inst.E.E.

Fulmen Works, Tunbridge Wells.

[97357.] — **Linoleum Paste.** — Melt and mix glycerine with glue; boil rice flour (1lb.) to thick paste in water (3oz.); next mix glue in little water, add treacle (2oz.) to paste; boil to required consistency. Four parts by weight of glue allowed to soften in 15 parts of water cold for some hours; then moderately heat until solution is clear; 65 parts of water now added and constantly stirred. In another vessel 30 parts starch paste are stirred in 20 of cold water till thin milky fluid obtained without lumps. Into this boiling solution of glue pour, constantly stirring, whole kept at boiling heat. After cooling, 10 drops carbolic acid added to paste. Preserve in closed bottles, will keep for years. Isinglass 7lb., gelatine $5\frac{1}{2}$lb., water 5gal., acetic acid $5\frac{1}{4}$lb., rectified spirits 4 pints. Soak isinglass and gelatine in the water for about six hours, then melt by heat; add the acid; boil until half the quantity by weight; cool, add spirit, and bottle.

REGENT'S PARK.

[97360.]—**Wehnelt Break.**—You must not expect much more than half the length of spark obtainable with a mechanical break. A good deal depends on the shape and bluntness of the anode. Your acid is too dilute;—about 5 parts acid to 21 of water by measure is the correct strength, and if the solution is used warm a much lower voltage may be employed. A tube that gets white hot will soon be ruined. A. H. AVERY, A.Inst.E.E.

Fulmen Works, Tunbridge Wells.

[97361.]—**Clock-Weight.** — There is no fixed ratio between weight of pendulum and motive-power; it depends on the finish of the clock, escapement, weight, shape and arc of pendulum, and firmness of fixing. If the two clocks are alike as regards escapement, arc of vibration, weight and shape of pendulum, and firmness of fixing, you will probably find that your clock has, say, pinions of eight leaves, and the Cooke and Son clock pinions of 10 or 12, as well as much smaller pivots, better depths, and lighter wheels. But if two clocks were built absolutely alike in every respect, I should expect them, when equally well fixed, to go and swing the same arc with the same amount of motive-power.

Ealing. F. M. MANN.

[97365.]—**Deafness.**—Chronic middle-ear disease is usually very intractable. You will not be able to do anything for it yourself; I should advise you to go to an eye and ear hospital for treatment. There is a tube leading from the back of the throat to the middle ear—the Eustachian tube; through this tube injections of a solution of caustic potash 3 in 2,000, a 2 per cent. solution of iodide of potassium, or a 1 per cent. solution of carbonate of soda may be made daily. If all these remedies fail, Gruber, the great Vienna specialist, gives, as a last and somewhat heroic measure direct injection without a catheter of a 1 per cent. solution of iodide of potassium. You will see that these suggestions need a specialist's skill, and that you yourself would not be competent.

Galway. M. B.

[97367.]—**Maximum Rainfall.**—"Pluvius" will have difficulty in obtaining information concerning maximum rainfalls for periods of less than an hour. To obtain even hourly values entails a large amount of labour, for they are, of course, derived from the curves taken off the self-recording rain-gauges, and are tabulated by means of a glass scale. In many of these curves, the time scale is

very small, and it would be difficult to tabulate intermediate values with any degree of accuracy. Moreover, such work would take considerable time, and the weather offices of different countries have not hitherto seen their way to devoting some of their energies to this desirable work, which, if undertaken for several stations where the records extend over many years, would, indeed, be no small matter. Engineers are, however, coming more and more to see the importance of information concerning the duration of individual rain showers, and the only way to get such information published is to agitate for it. NERPS.

[97368.]—**Reconstructing Organ.**—From the particulars you give, it is difficult to say what would be the best course to pursue, or what would be the probable cost of proposed alterations. Is the pedal action faulty, as well as that of the manuals? You say the pipes are good; but the chances are they will all want thoroughly overhauling and revoicing. The first thing I should certainly recommend is the carrying down of the swell manual to CC; this would be the greatest improvement of all. Your scheme for three manuals is not a bad one, and the third manual would certainly be a great addition; but I think, as your funds are only limited, probably the best course would be to have two new soundboards of full compass, new action throughout (tubular pneumatic for preference), new keys, as no doubt these rattle badly. Have the organ cleaned thoroughly, and the pipes revoiced. This would be far better than adding the third manual, and only getting the rest half-done. A question of this kind is difficult to answer without either seeing the organ or having further particulars; but if you will advertise your address in the "Address" Column of "Ours," I shall be pleased to communicate with you, and, when I had full particulars, could tell what your proposed alterations should cost, if carried out properly. DIAPASON.

[97371.]—**Prevention of Silver Oxidising.**—Your silver is not oxidised—it is sulphurised. You cannot prevent this with the existing condition of your atmosphere, except by giving the candelabra, after nicely polishing, a thin coat of clear celluloid varnish. When it is required to remove this, it can be done by washing over with amyl acetate.

S. BOTTONE.

[97371.]—**Prevention of Silver Oxidising.**—If very clean put in a tub of water in which some hyposulphite of soda has been dissolved. This will dissolve the black sulphide of silver; then clean and brighten thoroughly, and give a coat of collodion, put on with a camel-hair brush. If at a distance from a dealer in photographic materials, you can use the flexible collodion as used in surgery. Keep away from a light when using. M. COLE.

[97375.]—**Induction Coil.**—With such fine wire as No. 24 for primary, I should think you would find 50 sheets of tinfoil, 2in. by 4in., none too much for your condenser; 40 sheets 2in. by 2in. or 20 sheets 4in. by 2in. would give practically the same results. It is always better, when practicable, to wind a little floss silk over the joints. Paper cuts through so easily. A better plan is to paint the joints, after having cut off closely any snags of wire, with a little indiarubber solution. This, when dry, is an excellent insulation. A single pint bichromate cell will do all you require. Dry cells are practically of no use for coil-work, as they have such high internal resistance, and also because they run down so soon. Read Bonney's "Induction Coils." S. BOTTONE.

[97376.]—**Wheatstone's Bridge**—It is impossible to give exactly the length of any given gauge of copper or German silver wire that shall have exactly one ohm resistance. (1) Because the resistance varies with the temperature. (2) Because even the act of winding or unwinding the wire hardens it somewhat and increases its resistance. (3) Because no two samples of German silver wire have exactly the same resistance. However, annexed is a short table of the lengths of different gauges of copper and German silver wires that offer approximately one ohm resistance:—

Copper.		German Silver.	
No. 34	9·23ft.	No. 26	31·3in.
35	6·98	28	22·2
36	5·75	30	17·0
38	4·01	32	12·0
40	3·09	34	8·6
		36	6·5
		38	3·75
		40	2·9

Measured at 60° Fahr. S. BOTTONE.

A DOUBLE-TRACK drawbridge, weighing 600 tons, over the Chicago River, was recently shifted bodily a distance of 83ft. The method employed was to jack it up 26in. from its central pier, thus allowing a cradle to be built underneath it. This cradle ran on ways which were lubricated with tallow, and the weight of the bridge having been transferred to it, the whole was hauled bodily to its new position.

UNANSWERED QUERIES.

The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered, are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.

Since our last "Bazin" has replied to 97069.

QUERIES.

[97378.]—**To the Writer of the "Motor" Articles.**—I think there are several, like myself, who would like to make the sparking coil for tricycle motor. Would you please give a few particulars as to size, quantity of primary and secondary wire, condenser, and insulation? There are plenty of particulars of the making of coils in back numbers, so that the quantities for this particular coil are all that are required.—BUNNY.

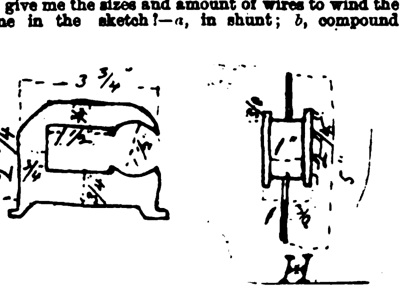
[97379.]—**Microscopic.**—I shall be pleased if some reader will tell me how to obtain a photo. of the eye of a fly, showing an object in each cell, or facet? I have taken one, showing the plain facets, but cannot manage the other. I should also like information as to how to mount the proboscis of a fly for the microscope. I have tried several times without success. I find it shrinks up when taken from the head. Canada balsam is the only medium I have tried for mounting.—W. R. WARD.

[97380.]—**Manchester Dynamo.**—Will some kind reader give me the dimensions of wire for a Manchester-type dynamo? The armature is made up of plates 2⅜in. diameter, with a hole 1⅜in. through. The armature is 3⅞in. long; the field-magnets 2in. diameter and 4in. long. The commutator has twelve parts. I would like the dynamo to charge accumulators.—THOMAS JOHNSON.

[97381.]—**Piston Speed for Launches.**—Can anyone give me a rule for the piston speed for small launch-engines? The formula 144 $^3\sqrt{}$stroke in inches does not apply to engines, say, under 50I.H.P. Any information will be gladly received.—C. E. L.

[97382.]—**Rats.**—I live in an old-fashioned country house, and lately we have been very much troubled with rats. Would any reader be kind enough to tell me how to get rid of them? I have a number of dogs, so I am afraid of putting poison down.—RATS.

[97383.]—**Dynamo.**—To MR. BOTTONE.—Would you kindly give me the sizes and amount of wires to wind the machine in the sketch?—*a*, in shunt; *b*, compound



wound. Also, the output and speed to be driven at in each case?—IGNORAMUS.

[97384.]—**Storage Battery.**—Can any reader give me any information respecting an "Epstein" storage battery containing 55 cells 13 plates? It was put in some years ago for a discharge at 50 amps. for six hours. The output has gradually fallen, until now it is practically *nil*. The battery has, so far as I can find out, received very fair usage. The appearance of the plates is good; they are not buckled, and the serrations are still distinctly visible—in fact, they (the plates) seem to have lost little or no weight. The S.G. seems normal, but the electrolyte turns very white, and foams a lot after one hour's charge at about 30 amps. I am told that this falling-off of output is very common in this style of plate. Can any reader give his experience in the matter, or any advice concerning the means of increasing the output? I intend to tackle it myself, having plenty of appliances to hand. What does Mr. Avery think about it?—ENGINEER.

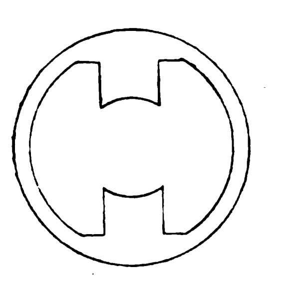
[97385.]—**Oxygen.**—In the Brin process of manufacture of oxygen where pressure is used, what pressure do you start at? How high does it rise before you begin to tap off your oxygen? How do you separate the nitrogen from the oxygen? What sort of retort is best to use? A sketch would oblige. What heat is required?—OXYGEN.

[97386.]—**Drilling Gold Quartz.**—I should be glad of any information which would enable me to safely bore a hole 2in. diam. and 2in. deep in a piece of gold quartz about 4in. long, 4in. broad, and 3in. deep. The sample is not homogeneous.—B. B.

[97387.]—**Frost on Window.**—Is there any solution that can be applied to window-glass to keep the frost off?—D. J. MCGREGOR.

[97388.]—**Match Composition.**—Can any reader tell me if the composition used for tipping matches has, or is being, used for other purposes than the above? If so, what are they?—ASHCROFT.

[97389.]—**Series-Wound Motor.**—Would Mr. Bottone or Mr. A. H. Avery be good enough to give me the size and dimensions of steel carcase, and diam. of armature, and gauges and quantities of wire, to construct



a series-wound 3B.H.P. motor to work on a 23?-volt circuit of the inclosed type, as per sketch, slot armature?—YOUNG ARMATURE WINDER.

[97390.]—**Electro-Deposit.**—Will some kind reader inform me whether it is practicable to electrically deposit metallic lead on cast-iron plates to a thickness of $^1/_{32}$in.? What apparatus would be necessary? I have plenty of power.—FUSE.

[97391.]—**Spun Glass.**—How is this done, and what kind of apparatus is desired? Any tips will be gladly taken by—CASENHEM.

[97392.]—**Tarnished Silver.**—How can I keep my Sheffield-ware silver candelabra on the sideboard without being tarnished (with gas, presumably), and having to be cleaned every few days?—CASENHEM.

[97393.]—**Telescope.**—I am thinking of getting an astronomical telescope, price to go up to about £16. Will some astronomical reader advise me of a good all-round instrument for home use? Would not a 3in. student's telescope with equatorial mounting be best?—F. B.

[97394.]—**New Moon.**—In *Whitaker's Almanac* of the current year I note there is no new moon in February. Will some of your astronomical contributors kindly state how long since there was a month in which the same occurred before, and when it will occur again? A similar answer with regard to the full moon would be interesting. —NEW MOON.

[97395.]—**Propellers.**—Will any readers kindly give me any information about propellers, the amount of slip, as it is called, or power that is lost? Is it the intermittent stroke of the blades where the power is lost? Also, could anyone tell what has become of patents such as Bovyer, Allison, Forrest and Myers, and others?—W. W.

[97396.]—**Gassner Cell.**—I have an exhausted dry cell—a large Gassner—and I want to revivify it. I have had two large Bunsen cells, in series, connected up with it—the carbon of Bunsen to zinc of dry cell—for thirteen hours, but this failed to waken it. Can anyone suggest a cause, and a remedy? Perhaps the cell is dried up. If so, will it be necessary to replace the mixture in the cell, and, in that case, what is the best?—C. H. W., Eccles.

[97397.]—**Aerial Ropeway.**—We wish to construct an aërial wire ropeway, 500 yards long, the carrying rope being supported on intermediate supports spaced 100 yards apart, the individual loads carried being one ton each, and the total number of loads on the whole length of rope at any one time not exceeding five, or a total gross load of five tons on the rope at once. One load on each span. Will any of "ours" kindly give calculations to show: (1) The horizontal strains on the terminal supports at each end? (2) The strains on foundations for these? (3) The weight required at the end of the carrying rope to give the necessary tension for the loads? (4) The vertical and horizontal strains on the intermediate posts, which would be about 16ft. high, each? (5) The horse-power required to drive the hauling rope for above, one end of the ropeway being 60ft. above the other, against the load, speed three miles an hour? (6) The hauling rope being an endless one, what weight will be required on the terminal pulley to give sufficient grip on the driving pulley?—ROPEWAY.

[97398.]—**Climate of China.**—What is the general climate of China, and what sort of weather do they have in the capital? I read that "Pekin, China, is frozen up for six months of the year, and the inhabitants enjoy ice-sledging at Christmas." Is that so, for the city is in about 40° N. Lat.?—F. F.

[97399.]—**Wireless Telegraphy.**—It is mentioned in some of the papers that wireless telegraphy cannot be practised with success in countries where there are ironstone mountains. Why is that?—W. M.

[97400.]—**Dynamos in Parallel.**—Can two dynamos be run in parallel, each designed to give 100 volts, but current for each respectively 350 ampères and 250 ampères?—ACC.

[97401.]—**White Brass.**—In the engineers' shop where I am at work they are using a metal similar to white metal for the main bearings of a crankshaft for a marine engine, and it is called magnolia. In another shop which I am acquainted with they are using similar

metal for the same purpose, which goes by the name of "white brass"; but I am told by a practical brass-finisher that he has never heard of such a metal. There is only one kind of brass, and that, of course, is yellow. Will any reader kindly tell me if they have ever heard of white brass; if so, I would like to know if it is a composition?—ENGINEER APPRENTICE.

[97402.]—**Windmill.**—Will someone who has a Chicago aërmotor, or knows their make, kindly give a sketch or sketches of the mechanism of this windmill, showing especially the arrangement for "feathering" or altering the angle of the vanes according to the velocity of the wind. I am told that, with a 14-mile wind, a 16ft. diameter mill develops 5 nominal H.P. Is this so? Also, that it stands a cyclone without being blown down, owing to its perfect feathering.—WINDMILLER.

[97403.]—**Accumulators of Woven Glass.**—Can anyone who has experience of these "glass" accumulators give particulars as to their efficiency and durability?—WINDMILLER.

[97404.]—**Wilson's Four-Cylinder Locomotive.**—Robert Wilson is said to have built an engine with four cylinders in 1826. Can any reader give me any particulars of how it worked? Was it simple or compound?—LOCOMOTIVE.

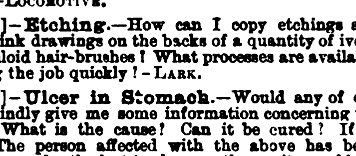
[97405.]—**Etching.**—How can I copy etchings and pen-and-ink drawings on the backs of a quantity of ivory and celluloid hair-brushes? What processes are available for doing the job quickly?—LARK.

[97406.]—**Ulcer in Stomach.**—Would any of our friends kindly give me some information concerning the above? What is the cause? Can it be cured? If so, how? The person affected with the above has been wasting away for the last twelve months; quite unable to keep any solid food down for the last three months. About seven weeks ago began to vomit a large quantity of what appeared to be congealed blood; this continued for several hours, and then ceased. Could this have been the ulcer broken in the stomach? The person in the mean time has been very low, and has lived on milk ever since. Is this sufficient to sustain life until the patient recovers from the effects, or will the ulcer gather again?—TEMPUS FUGIT.

[97407.]—**Carburetter.**—I have a 4½H.P. benzoline motor with a surface carburetter, and shall be very grateful if "Monty" or others of our practical readers can tell me what number or size Longuemar carburetter is suitable for this engine? Would this carburetter do away with the pure-air valve, and give as good, or better, results? Any information about the Longuemar will greatly help.—AMATEUR.

[97408.]—**Alignment of Machine Tools.**—Having a number of new tools to examine and test for alignment, I wish to know the best way to proceed. I have no gauges or trammels at my command, but would make them if some kind reader would give a few hints. The tools include centre, chucking, and turret lathes, horizontal boring, universal milling, radial arm drilling, and planing machines. Perhaps "J. H." could give an idea of the methods adopted in tool-shops? Is there any book published on the subject?—ANXIOUS TO KNOW.

[97409.]—**Axle to Motor-Car.**—Will the writer of articles on "Motor Tricycles" kindly advise what size live axles to use for 4H.P. two-seat motor-car? Also, if



differential gear will answer if placed between hub and spring, as per sketch.—MOTOR-CAR.

[97410.]—**Dry Battery.**—Can one of these batteries be recharged by attachment to the switch for lighting an electric lamp?—BATTERY.

[97411.]—**Edison-Lalande Battery.**—Could any reader oblige by letting me know how the Edison-Lalande batteries are worked, as I have several, and am in a fix? Fullest particulars, as I am some parts short.—G. B., Aston.

[97412.]—**Meridian Passage of Stars Locally.**—In your "Astronomical Notes for January" the writer endeavours to give an explanation as to how to find the local time of southing of any given star at any other station than Greenwich, and this chiefly for the benefit of your younger readers. Now, I am certain to 90 per cent. of such the explanation as given will only mean confusion, for local mean time to them at least will simply mean the time used locally, and which the writer will know is, for any part of England, Greenwich Mean Time. Why he has introduced local mean time in its true sense when such a thing is not in use, one is at a loss to understand. α Arietis will south at Falmouth 20m. 8s. − 3·30s. = 20m. 4·7s. after the time of southing at Greenwich, Greenwich Mean Time being used.—W. B. D.

THE output of coal in Great Britain this year is expected to reach 225 million tons, of which about 50 million tons is for consumption by our Royal and mercantile navies and for export.

THE first electric launch to be used on the canals of Venice has made its appearance. A syndicate has taken the matter up and secured this first launch as a type of what they wish to run for passenger traffic on the canals subject to the approval of the local authority. The launch, which is called the *Alessandro Volta*, provides accommodation for about 50 passengers. Its length is about 56ft., and width 10ft. It is equipped with 100 accumulators, and its mean speed will vary from seven to nine miles per hour.

ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries, put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

*** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

The following are the initials, &c., of letters to hand up to Wednesday evening, Jan. 10, and unacknowledged elsewhere:—

S. R. BOTTONE.—A. Jacks.—J. W. Riding.—Turner.—Astronomicus.—Bolter.—J. A. C.—James Wright.—Major.—G. T.—G. B., Aston.—J. E. L.—Arcturus.—Jack of All Trades.—William Godden.—Photo.—H.—Davison and Reed.

MARK.—Can only refer you to the textbooks of astronomy. We have not the slightest idea "at about what date" it was "discovered that the moon does not shine of its own light." It is not impossible that Adam discovered it. (2) It appears to be definitely established that the whole solar system, as we know it, is travelling through space. (3) There is a "well-founded theory" that the "earth will ultimately come to grief." Please refer to the back volumes.

G. J. C.—Not now, except that a speed limit is enacted and local authorities can make by-laws. The inspector at the police station can tell you. Furious "driving" is a matter for the attention of the police. No license required unless you carry passengers and ply for hire.

R. MOORE.—There have been so many articles on the subject that we cannot recognise which you mean. You might look through the indices of the ten volumes preceding this. They are most likely in one of the free libraries near you.

INCOGNITUS.—Walker's is still a very useful dictionary. "Rhyme" means words expressed in "numbers"—that is, verse, poetry. "Rime" means hoar-frost, Anglo-Saxon "hrim." The second question is answered by saying that the best pronunciation is "wer," the e being sounded as in "met." To "run wild" would mean to go recklessly; to "obtain"—the "doctrine *laid hold of*," in the sense given. The "day wears" means that its duration is lessening. The "shoe gives" means that it yields. As to what it is necessary to do on London Matriculation papers, we must refer you to the papers themselves, or to such a work as the "London University Guide," published by the University Correspondence College Press, Burlington House, Cambridge.

MG. HPAW, Moulmein.—The tinned (or canned) provisions, whether meat, jams, fruit, milk, &c., are placed in the tin cans, the lids soldered down, and a hole left for the escape of air, steam, &c. They are then placed in a vessel, and subjected to a temperature high enough to drive out the air and vapour, when the hole is closed with a drop of solder, thus producing a sort of vacuum. Jams are preserved by boiling in sugar.

W. T. H.—There is an illustrated description of Joy's oil valve-gearing on p. 236, No. 1493, Nov. 3, 1893; of the gearing as applied to a locomotive on p. 572, No. 1481, Aug. 11, 1893; and the original as applied to marine engines was described in the back volumes. We think the inventor published a card of instructions, but the arrangement is described in most of the manuals.

OLD READER, Burton-on-Trent.—The material generally used for sealing cells is pitch; but for a full answer you must really give some more information about the "pocket accumulator."

J. W., Birmingham.—Letter is much too long and covers too much other ground. We cannot in these columns discuss the whole question of field tactics.

Carbide of Calcium.—A Russian engineer (M. Orlowsky, of St. Petersburg) has made an improvement in the manufacture of calcium carbide, which has for effect the prevention of the absorption of damp and the more regular and slower evolution of acetylene when in contact with water. He places the carbide just when it comes from the electric furnace, and whilst still hot, in a mixture of one part of tar and forty parts of petroleum residues. It is also reported that Herr Wolff, of Berlin, has patented a process for its manufacture which entirely does away with the electric furnace. A compound of lime, carbon, and powdered aluminium is mixed together, and then fired by a slow match or torch. The aluminium, it is said, combines with the oxygen of the quicklime, and the temperature thus caused is so high that the lime melts and combines with the carbon.

CHESS.

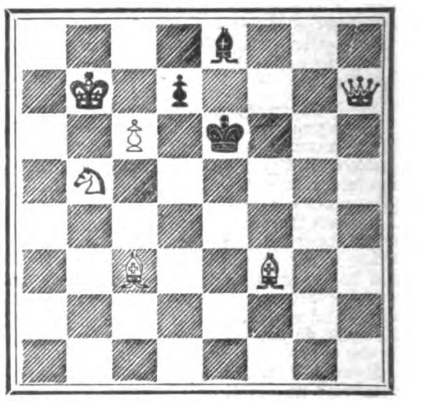
PROBLEM No. 1709.—By J. JONES and W. SHINKMAN.

Black. [3 pieces.



White. [6 pieces.

White to play and mate in two moves.

(*Solutions should reach us not later than Jan.* 22, 1900.)

Solution of PROBLEM No. 1707.—By J. GRAVES.

Key-move, B-B 2.

NOTICES TO CORRESPONDENTS.

PROBLEM No. 1707 (incorrectly numbered 1706).—Correct solution has been received from J. E. Gore, G. W. N., Quizco, Richard Inwards, Rev. Dr. Quilter, F. B. (Oldham), A. Tupman, F. Gowing, N. M. Munro.—Only solution as above.

H. B. F., W.-H., W. E. C.

THE British Chess Company are distributing copies of the wall-sheet "Laws for the Regulation of Games Played over the Board," being Part II. of the British Chess Code (revised edition). These are intended for use in Chess clubs, reading-rooms, Chess resorts, &c. Should any of our readers desire this wall-sheet, they are requested to send the address of the club or room in which Chess is played to the British Chess Company, Stroud, Glos., and a copy will be sent without charge.

AN American engineer, Mr. Chas. T. Porter, in the discussion on Prof. Thurston's paper, read before the American Society of Mechanical Engineers, described the plans which he has for the construction of a steam-engine which shall produce a horse-power for 9lb. of steam per hour. The plan consists chiefly in the use of high pressures, high ratios of exhaustion, high piston-speeds, and a system of reheaters by which condensation would be avoided.

The Food of Plants.—An instructive and entertaining glimpse of the mysterious processes by means of which plants secure their food is given by Mr. H. H. W. Pearson in the current number of *Knowledge*. He says: "It is more than 2,000 years since philosophers began to speculate about the food of plants and what we may term their 'digestive' processes, but it is only during the latter half of this century that really clear and definite notions concerning the food supplies of the vegetable world have been generally accepted by scientific men. . . . As far as is known, the first botanical experiment ever performed was conducted by Van Helmont. He placed in a pot 200lb. of dried earth, and in it he planted a willow branch which weighed 5lb. He kept the whole covered up, and daily watered the earth with rainwater. After five years' growth, the willow was taken up and again weighed, and was found to have gained 164lb.; the earth in the pot was dried and weighed, and had only lost 2oz. Knowledge was not yet sufficiently advanced to enable Van Helmont to interpret these striking results correctly, and he came to the erroneous conclusion that the increased weight of the plant was due to the water which had been supplied to the roots. He therefore looked upon this experiment as supporting the theory which he had advanced—viz., that plants required no food but water." Stephen Hales advanced the subject a great step by indicating that much of the increase in weight of plants was derived from carbon dioxide in the air. Vegetable cells contain a liquid known as "cell-sap," which is water holding in solution various materials which have been taken up from without by the roots and leaves. "These materials are thus brought in contact with the protoplasm, which causes them to undergo changes in composition which prepare them to be added to the substance of the plant. Thus it is in the protoplasm of the living cells of the plant that those 'digestive' processes are carried on which Aristotle believed to occur in the soil. We see, then, that the living cells are microscopic laboratories in which the digestion of the food of the plant is carried on."

The English Mechanic
AND WORLD OF SCIENCE AND ART.

A SMALL MOTOR-CAR, AND HOW TO BUILD IT.—III.

THE cylinder, which is of cast iron, is shown in Fig. 4, which is a side elevation showing the facing for the valve-box. Fig. 7 the square flange which goes next to the crank-chamber. Fig. 8 shows in the upper part a cross section on the line C D of Fig. 4, the lower part being a cross-section on the line E F (Fig. 4). Fig. 8 also gives dimensions for the studs, which hold the valve-box on to its facing. Fig. 9 is a section on the line A B of Fig. 6, showing the depth of the bosses and dimensions of the studs which hold the cover on to the cylinder. The bosses G (Fig. 4), shown dotted, run through the water space, connecting the water-jacket walls to the cylinder. The dimensions of the facing for water-inlet and outlet pipes shrinkage allowances, prints being put on for the bore and the various openings in the sides. For the water connections, plain cylindrical prints; on the valve-box facing, one rectangular print to include cylinder port and water-jacket opening, will be required. Observe in Fig. 5 that the interior of the cylinder is chambered out $^1/_{16}$in. larger in diameter for the combustion chamber. This, though not absolutely necessary, makes a better job of it, allowing the boring tool to be free from the cylinder port, and also preventing the piston from wearing the cylinder-bore to a shoulder. At the extreme back

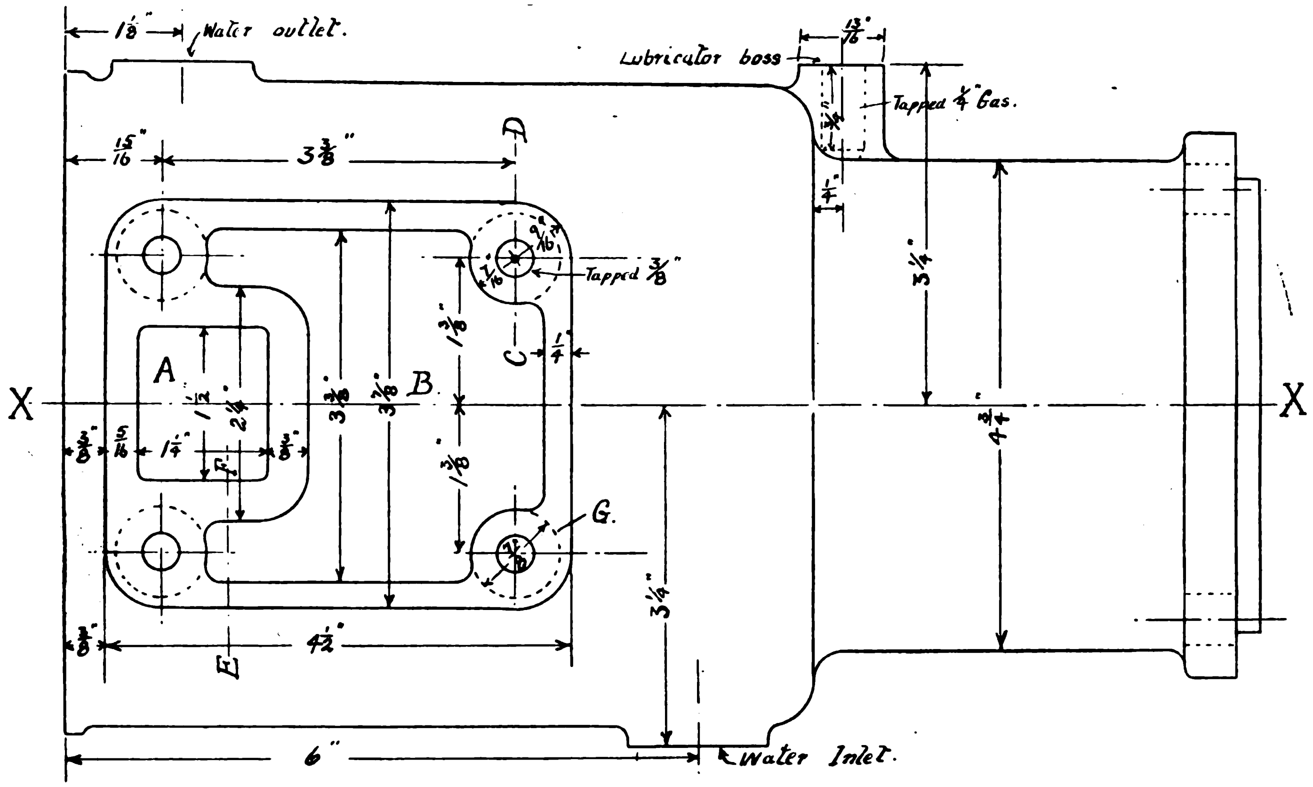

FIG. 4.

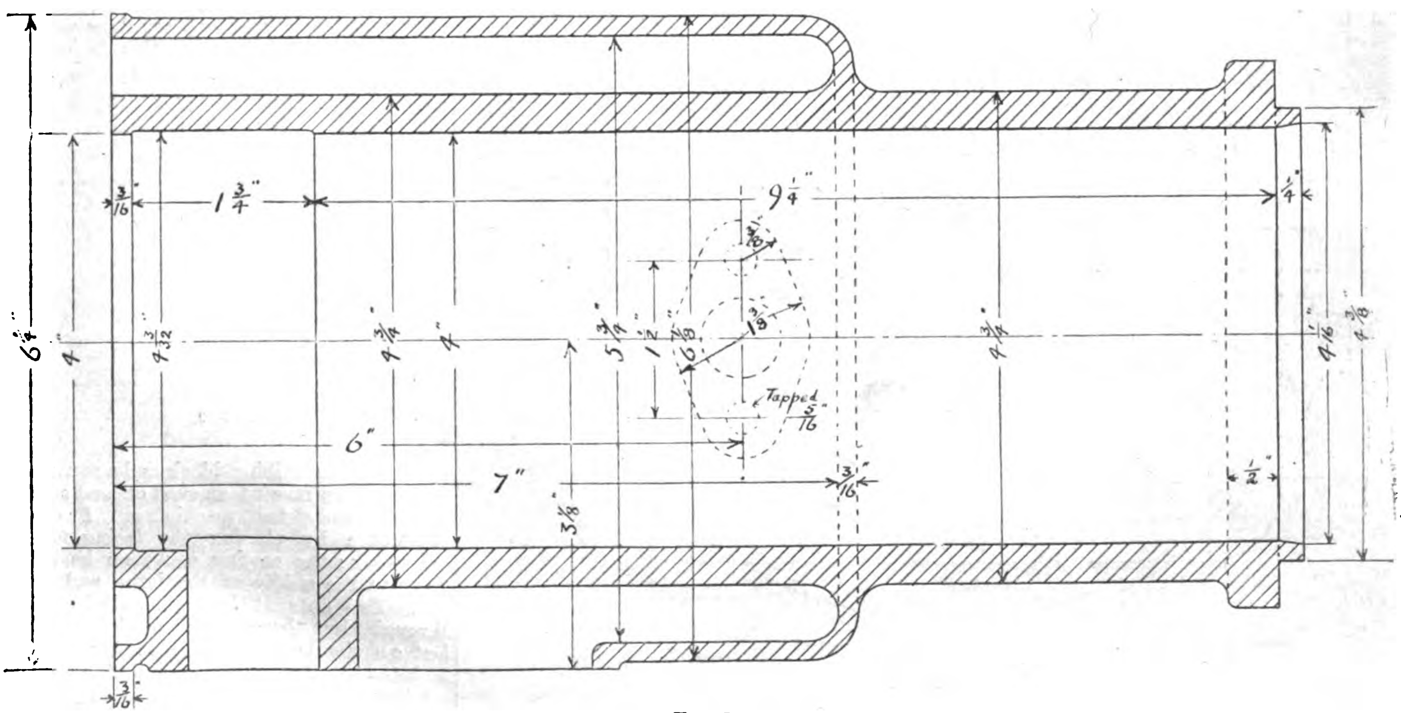

FIG. 5.

A is the port communicating with the combustion space, and B the opening to the water space around the cylinder. Compare this view with the sectional plan (Fig. 5) and the end elevations (Figs. 6 and 7). Fig. 6 is the combustion-chamber end, and may be obtained from Fig. 5, where the inlet facing is seen dotted. The central hole in these facings is $\frac{3}{4}$in. diameter, and is cored through into the water space.

The pattern for the cylinder will be made exactly as its casting, plus machining and end of cylinder, the bore is again reduced to 4in. for $^3/_{16}$in. in length, to form a fitting for the cover to check into. At the front, or crank-chamber end, the mouth of the bore is slightly enlarged to enable the piston and rings to be readily inserted. The cylinder

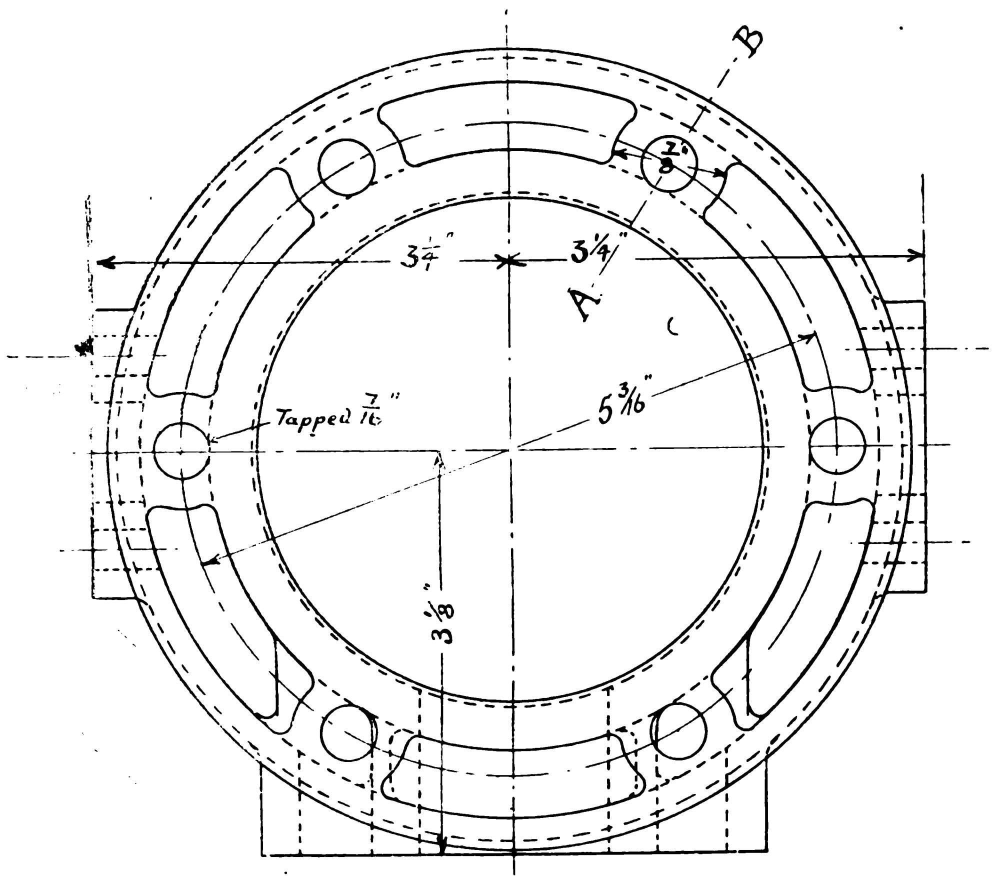

FIG. 6.

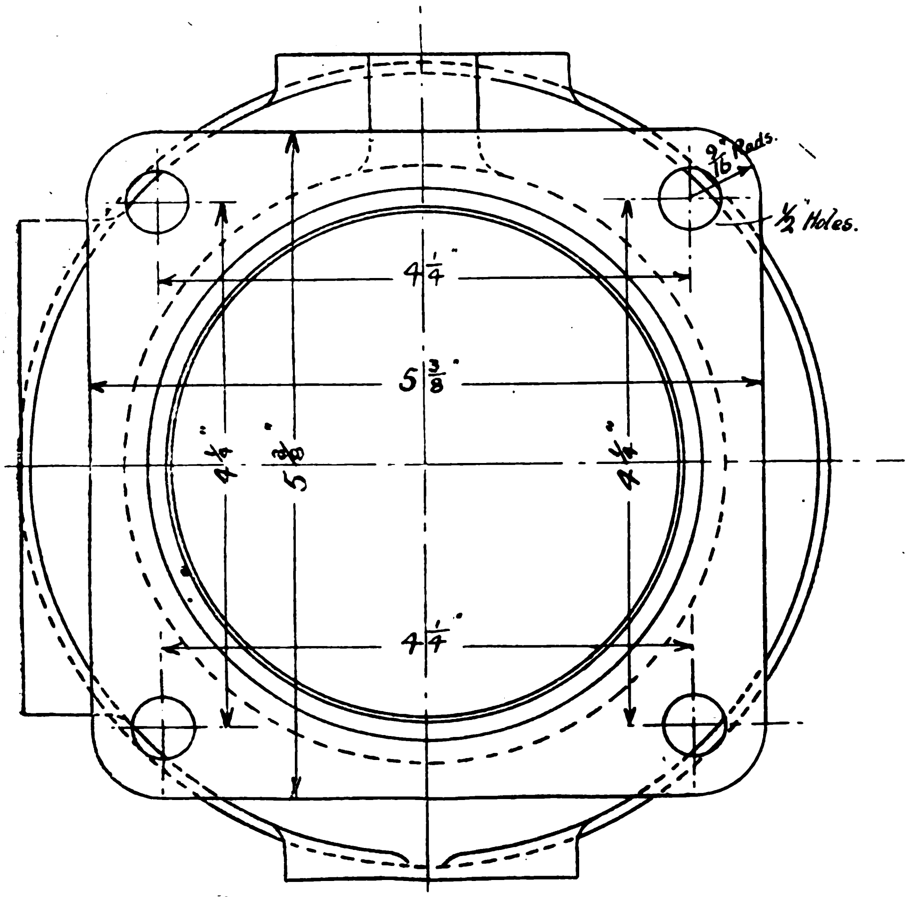

FIG. 7.

will mould with the facing for the valve-box on one side, and the pattern should therefore be jointed along the line X X, in Fig. 4. The water space is cored out, the print for the cover end being included in the print for the bore. This print should be a good length, say 4in. or 5in., to balance the overhanging portion. The hole through the jacket for water inlet will also enable the jacket-core to be supported. The use of chaplet nails for supporting this core is to be deprecated, as they tend towards leakage. To insure a sound casting, the cylinder should be cast in dry sand, and every care taken to avoid blow-holes. The bosses D, Fig. 6, for the cylinder-cover studs are arranged for in the jacket core-box. In this core-box a wooden cylinder to give the metal for the cylinder is arranged so that it can be withdrawn endways (in a direction away from the combustion-chamber) before the core-box is opened. The combustion-chamber end of the main cylinder core is carried inside of, and concentric with, the portion of the jacket core which lies in the space made for it by the large print on cylinder end. The cylinder core need not enter the jacket core more than an inch or

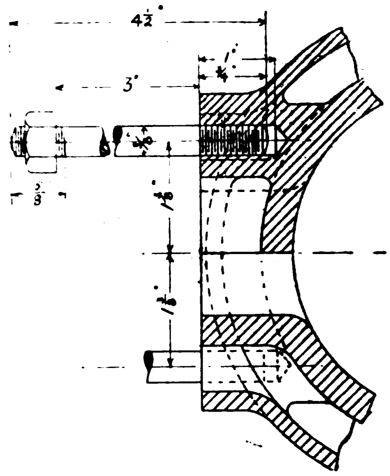

FIG. 8.

so, as this will be quite sufficient to centre and support it.

Having obtained the casting, whiten it with chalk, and proceed to mark it off for machining. Bridge the ends of the bore with a strip of hard wood; find the centre, averaging the metal to be removed, so as to keep the walls as even as possible in thickness. Mark out circles for the bore at each end and witness circles 1-16in. all round these, and centre-pop at about ⅛in. intervals all round each circle to avoid obliteration. Block up the casting on a level surface, getting the centres at each end exactly equidistant from the marking-off table. The facing for the valve-box should be vertical. Mark a centre line across this facing, and also across each end of the cylinder. By

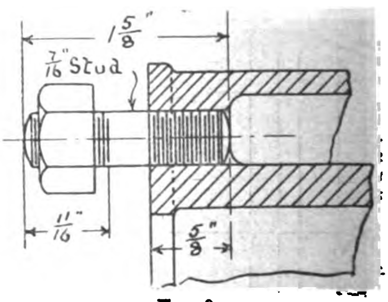

FIG. 9.

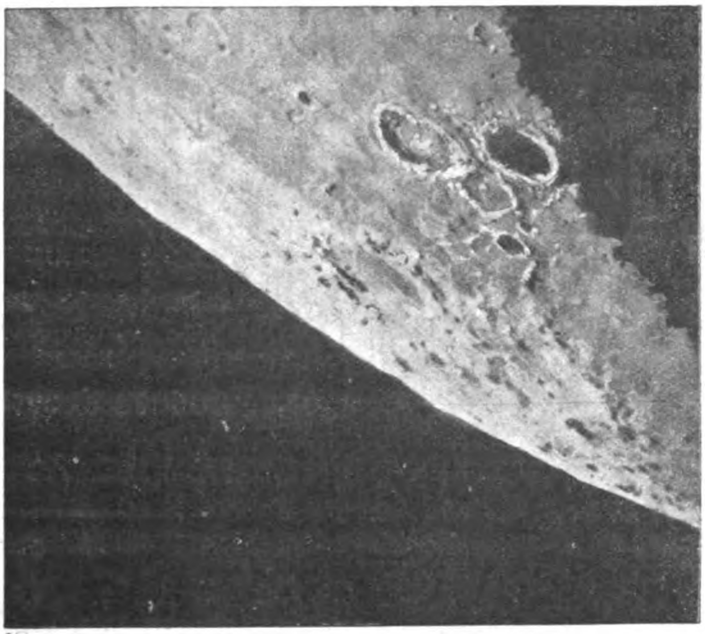
means of the scribing-block and a square, all the faces can now be marked off and centre-popped ready for machining. I should commence by planing the facing for the valve-box; the casting can then be bolted down to the saddle of the lathe and bored out. Two cuts at least should be taken through, but three would be better. The last cut should be just a scraping cut with a broad-pointed tool, using a fine feed to get the bore as smooth and true as possible. At the same setting the ends of the cylinder can be faced and the bore bell-mouthed, using properly-shaped cutters, or the cylinder can be mounted on a mandrel and the ends turned off to the correct dimensions. After boring, the remaining facings can be machined and their stud-holes drilled and tapped.



Atlas and Hercules.

The stud-holes on valve-box facing and for cylinder cover had best be left until the box and cover are drilled, and be marked off from them. The four holes in the square flange, can, however, be marked off and drilled at this stage. The lubricator boss is to be drilled right through $^3/_{16}$in. diameter, and then enlarged or tapped $\frac{1}{4}$in. gas for $\frac{3}{8}$in. in depth. The water-connection facings are furnished with two studs each, the studs to be $^5/_{16}$in. diameter and to stand up $\frac{3}{4}$in. above the facings. In drilling the holes for these studs you can drill right through into the water space, as there will be no leakage if the studs are made a good fit to the tapped holes.

THROUGH A SMALL TELESCOPE.—V.

By NORMAN LATTEY.

CONTINUAL cloudiness, with a persistence that seemed almost malicious, sadly interfered with observations of the moon during the period between "new" and "first quarter" of

Double Cluster in Perseus.

the present lunation. As, however, it is possible that clearer weather may attend the birth of the young crescent at its reappearance on the evening of the 31st of this month (the "new" actually occurs at 1.23 in the morning), it will be as well to draw the reader's attention to a few of the principal formations, which are the first to be slowly revealed after their immersion in the inky darkness of the long lunar night.

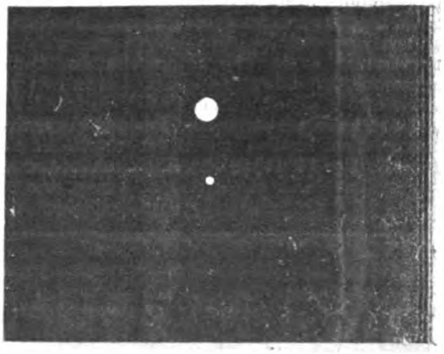
A reference to any map of the moon (Messrs. Geo. Philips and Son, of Fleet-street, London, publish a splendid one by the late T. Gwyn Elger, F.R.A.S., at 2s. 6d. unmounted) will easily enable the student to identify the various objects about to be described—that is, if he is not already familiar with their shapes and positions. The most conspicuous formation that will be noticed under a low power—40 to 60 diameters—when the moon is two or three days old is the Mare Crisium, just below the widest part of the crescent. Here lies a scene of almost supernatural beauty, and one which offers an entire evening's fascinating study of its precipitous cliffs and winding valleys encompassing the smooth level interior, pierced here and there with tiny craterlets. Among the prominent ring-plains situated on the surrounding heights is Condorcet, 45 miles in diameter lying at the base of Cape Agarum, that little promontory jutting out into the sombre depths of the *mare* on its north-western "shore." Condorcet is encircled by a lofty wall 8,000ft. above its floor, and possesses a decidedly dark interior.

Let us, however, now put on a higher power, about 120, and commence operations systematically at one end of the crescent, say the uppermost or southern cusp (it should be remembered that an astronomical telescope inverts and the north is invariably at the bottom of the picture, though the east and west retain their normal positions). Almost at the very tip of the horn will be noticed the western spurs of the loftiest range on the moon, the Leibnitz mountains, which stretch right across the pole. Of course, the remainder of this stupendous chain is at present steeped in darkness, but it contains one peak at least 27,000ft. high. Glancing further down, the eye is not long in resting on a striking formation, Furnerius, the first of a chain of four magnificent walled plains stretching northward for 600 miles towards the equatorial regions. As will be seen, Furnerius is an irregular inclosure of greater breadth than length, the latter being about 80 miles. Its rampart is very lofty, and on the eastern side of the floor will be perceived a smaller ring-plain containing a little central hill. Not far below lies a still more superb object, Petavius (the second member of the chain). Extending for nearly 100 miles from north to south, its grand double rampart incloses a broken convex interior, in the centre of which stands a closely grouped pile of central mountains, one peak of which rises 6,000ft. above the floor. The most striking feature of this colossal crater is a huge gash or cleft which cuts diagonally across the interior from the central mountains to the south-east wall. It can be clearly discerned with a 2in. telescope. The eastern rampart, which is intricately terraced, rises to enormous heights, especially where the companion ring-plain Wrottesley encroaches upon it. Here the peaks rear themselves up to 10,000ft. above the floor. The western wall is, however, comparatively much lower, rarely exceeding 6,000ft. in altitude.

In Vendelinus the third of this series, we have the most irregular formation of the four, with its low broken rampart, scored and hollowed by many clefts, rings, and depressions. The continuity of the western wall is completely broken by a good-sized ring-plain some fifty miles in diameter; and in the southern border is a wide gap partially closed up by another ring-plain. On the eastern wall are several high peaks, two of which cast spire-like shadows on the floor under evening illumination—i.e., immediately after "full moon," when night again begins to creep over the shining disc, warning observers that the lunar day is drawing to a close. Should an opportunity be afforded, drawings will be made of one or two of the foregoing features at that favourable period.

Langrenus, the most northerly of the quartette, may well be ranked among the finest objects on the Moon; but it, in common with the previous three, suffers greatly from the foreshortening effects of the moon's spherical surface, a circumstance which robs it of much of its stateliness. Its almost continuous ring ranging from 8,000 to 10,000ft. in height, is close upon 90 miles in diameter, and deeply terraced on the inner slopes. A brilliant central mountain adorns the interior plain, while bright streaks stretch out into the Mare Fœcunditatis from the eastern flank of this vast formation.

Crossing the Equator we once more find ourselves on the shores of the Mare Crisium (already referred to). But we must not linger. Several important objects have yet to be examined. The



ε Persei.

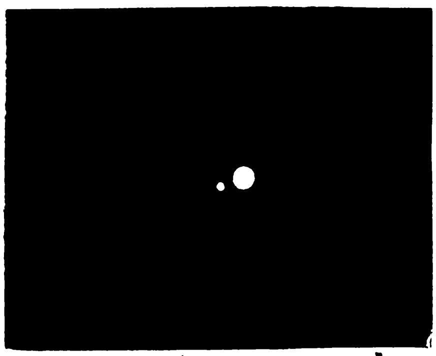
most notable in this district is Cleomedes at the north end of the *mare*, a large oblong inclosure 78 miles in diameter, its massive walls rising 8,000 to 10,000ft. above the interior. On the western wall under a rising sun, when about one-fourth of the floor is in shadow, three depressions curiously shaped like the figure ∞ can be easily distinguished. Still further north, and almost on the edge or "limb" of the moon, is Gauss, a circular-walled plain 111 miles across. Owing to its situation it also is much foreshortened into an elongated ellipse with a very broken border. A magnificent mountain chain stretches from north to south across the floor, which is sprinkled with several large rings, craters, hillocks, &c.

Hard by is Geminus, a smaller ring-plain with steep terraced walls towering up 12,000ft. to 16,000ft. It must be borne in mind that terrestrially compared, these altitudes far exceed anything we can boast of on the earth. Reduced to the moon's more diminutive sphere Mount Everest's 29,000ft. would shrink to a trifle over 8,000. Terrestrial peaks of more than ten miles in height would be required to rival the lofty summits of Geminus.

There are many more important features favourably placed during the first five days succeeding the "new," notably two fine ring-plains Guttenburg and Goclenius situated on the narrow strait dividing the Mare Fœcunditatis from the Mare Nectaris. There is, likewise, a remarkable pair known as Messier lying almost in the middle of the Mare Fœcunditatis. The latter undergo curious changes as the sun draws overhead, and are connected with two remarkably light streaks and dusky spots, the nature of which still defies explanation. It is to be hoped that meteorological conditions will permit of sketches of a few of these interesting objects at the next lunation. In the mean time we must conclude our survey this week with

Atlas and Hercules which lies on the terminator near the lower or northern horn when the moon is about four and a half days old. At the time of making the drawing, which is a copy of a photograph with the finer detail, lights, and shadows filled in at the telescope), Atlas, it will be noticed, is well within the lighted area, and its rather dusky interior clearly illuminated by the morning sun. Its much broken and irregular walls present a most complex circumvallation scored by innumerable ridges and clefts. Even in a small telescope it offers a striking and bewildering spectacle far beyond the power of words to describe or pen to adequately delineate. Hercules, its companion formation, is still struggling out of the embrace of night, its depressed floor, 46 miles in diameter, being yet steeped in blackness, but surrounded by a brilliant ring of light where the morning rays are tipping the lofty summits of the border. Viewed under a higher sun, Hercules presents a wonderful sight with its remarkable terraces, landslips, and depressions. Endymion, the ghostly-looking walled plain nearer the sharply defined rim, is also surrounded by lofty peaks, but they are better seen a day or so earlier.

Snatching a fleeting opportunity during a brief period of clear sky one evening, a few stellar observations were obtained—chiefly in that rich constellation Perseus lying between the W of Cassiopeia, and the glittering group of the Pleiades. The most conspicuous object in the latter is of course the double cluster which appears to the naked eye like a globular haze of nebulous light—as if a bit of the Milky Way had got condensed; a simile probably not far from the truth. This splendid twin cluster consists of a large number of 6½ to 14 magnitude stars aggregated together in two dense groups. The figure as nearly as possible gives a correct representation of what it looks like through a 4in. Cooke refractor stopped down to 3in. and armed with a power of 60. The object can easily be found, for it lies right on the confines of Perseus where that constellation borders on Cassiopeia (R.A. 2h. 11m. N. Dec 56° 36′) η Persei is a pretty 4-mag. star with a bluish companion of 8 mag. but its

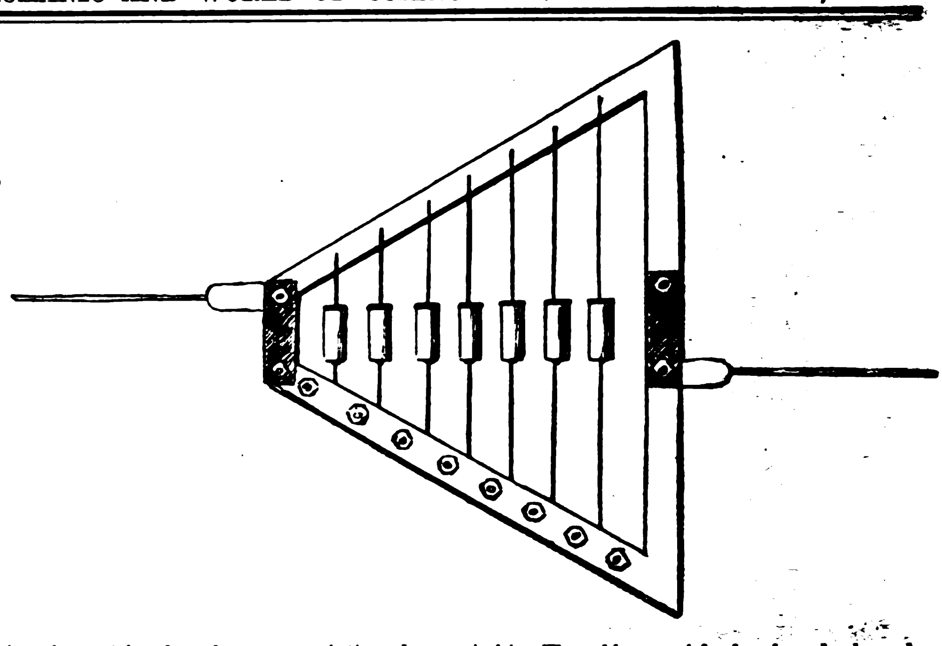


γ Ceti.

distance 28″ is too wide to conveniently represent here on our present scale. β Persei (the famous variable star Algol) "The Demon" of the Persians, is worth watching on account of its remarkable fluctuations. Shining with a constant brightness as a 2-mag. star for about 59 hours, it suddenly diminishes in lustre until in about 4½ hours it sinks to 3½ mag., at which, however, it only remains for some 15min., when it immediately begins to rise again. In about five hours the star recovers its normal brilliancy of 2 mag., all the changes being gone though within ten hours, although sixty-nine actually elapse between the successive minima. ζ Persei is a pretty specimen of a quintuple. The primary of 2½ mag. has four companions, one of 9½, two of 10, and one of 12 mag. On a dark, clear night the 9th and 10th mag. *comes* may be detected with a small instrument, but they need some looking for. ϵ Persei, on the other hand, is an object as easy as it is beautiful, with its 3½ mag. primary and 8 mag. companion, and the figure gives a good idea of the appearance of this star under a power of about 200.

Though rather low down in the south there shines an object γ in the constellation Cetus (The Whale) which is well worth examining. It can easily be found, for it is the nearest conspicuous star to α Ceti, which forms an equilateral triangle with the Pleiades and α Arietis, the apex of the imaginary triangle, of course, pointing downwards towards the horizon. An inspection will show γ Ceti to be a fine 3½-mag. star with a greenish companion only 2½in. distance. It may be a minute or two before the *comes* can be discerned, but steady gazing will ultimately show it quite plainly involved in the diffraction rings surrounding its glaring primary.

The instrument was again a 4in. photo-visual refractor by Messrs. Cooke and Sons, of York and London, its aperture stopped down to 3in. as usual.



A SENSITIVE COHERER FOR WIRELESS TELEGRAPHY.

A MODIFICATION in the construction of the old form of coherer, which exalts the sensitiveness and range of receptivity of the receiver, has just been perfected by Messrs. S. Bottone and Son, of Wallington. It consists, as shown in the cut, of a number of metallic cells, fitted with tightly-fitting ebonite caps. The cells contain filings of different grades of fineness, of an antimony alloy, having different electrical resistance. These cells are supported, as on stalks, by different lengths of platinoid wire, and through the caps, passing downwards so as to reach the filings, are inserted varying lengths of similar wires. Finally, the bottom and top sets of wires are electrically connected to two insulated half-triangular brass frames, each half being connected by suitable wires to the terminals of the receiver. Owing to the varying resistances in the cells themselves, and the varying capacity of the wire extensions, such a "multilocular polytonic coherer" is capable of responding, not only to very minute wave disturbances, but also to Hertzian waves extending over a very wide range.

THE STRENGTH OF RUBBER HOSE.

THE introduction of steam heating in railway carriages has made it necessary to provide rubber hose connections which shall stand the rather severe duty of this peculiar service. In the case of air-brake hose, the problem is confined to securing tightness against leakage of air under pressure, and endurance of the wear and tear of operation and handling. For steam heating connections, however, there are effects of steam and the action of hot water to be considered, and experience has shown the necessity of providing strict specifications and exhaustive tests, in order to insure satisfactory results.

A series of tests has recently been made at the Government Testing Laboratory at Charlottenburg, and the results are now made public in a paper in the *Mittheilungen*, by Prof. Rudeloff, and as the subject is one of international interest, an abstract of his paper is here given.

The requirements of the German Government for steam hose are very strict, and are in substance as follows:—

The hose is to be made with five layers of pure linen, with sheet rubber between, and is to be covered without with linen. It must stand an internal pressure of 150lb. per square inch, either hot or cold, without injury, and when subjected to internal pressure of 60lb. for four hours, should not twist. The rubber must be free from foreign substances. A temperature of 350° Fahr. sustained for four hours should not affect the strength, nor injure the hose in any way. The presence of hot water under pressure should not cause the linen to be easily separated from the rubber, nor the layers of rubber from each other.

Holding these requirements in mind, the tests made by Prof. Rudeloff may be considered in brief.

After a careful measurement and inspection of the samples they were subjected to an internal pressure of 150lb. with water at the temperature of the air, with water at 170° Fahr., and with steam pressure. A pressure of 60lb. was then maintained for three hours, and an inspection for defects then made, after which the sample was subjected to a heat of 350° Fahr., both with steam and with dry heat, and the strength of the material then examined. The adhesion of the linen to the rubber was also determined, both for the original condition and after exposure to the action of boiling water.

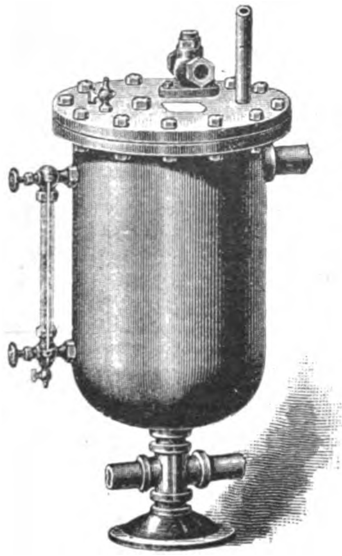
The specimens tested were about 22in. in length, 1⅜in. internal diameter, with walls ¼in. thick, and examination showed that the rubber penetrated the fibres of the linen so that it appeared to be of one entire mass. A number of samples were tested, and the results are tabulated fully in the original paper, together with a description of the apparatus used. The circumference of each piece was carefully measured near each end, and in the middle, both before testing and afterwards, as well as during the application of the pressure, and similar measurements were made of the length.

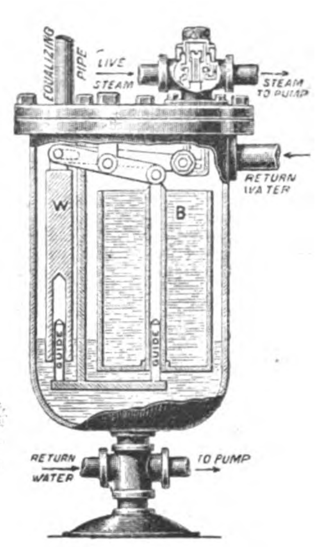
So far as resistance to cold water pressure is concerned, the specimens tested gave excellent results, the slight increase in diameter under 150lb. pressure disappearing entirely when the pressure was relieved. The corresponding tests with water at 170° Fahr. resulted in a permanent increase in circumference of about ¼in., but the hose appeared otherwise unaffected. The specimens, however, failed to resist satisfactorily the test of 150lb. steam pressure, as the circumference was enlarged nearly 1in., and the length diminished 0·6in., while the outer covering was loosened and partly destroyed. The twisting action which takes place consequent upon prolonged internal steam pressure was shown by the fact that one specimen twisted 15 degrees when under steam pressure of 60lb. for three hours, with a permanent twist of 8 degrees, and another specimen showed 9 degrees twist and a permanent set of 2 degrees.

The action of prolonged heat varied according to the manner of application. Rings cut from various portions and opened out were pulled in the Rudeloff testing-machine, both in the original condition and after heating. Exposure to steam heat at 350° Fahr. for four hours made the rubber much softer, the extensibility under given load being increased fully three times, and the ultimate strength diminished to less than one-fifth its original amount. Exposure to dry air at 350° Fahr. for four hours, on the contrary, made the rubber harder, and diminished the extensibility very greatly, although the ultimate strength was reduced nearly as much as with the steam.

When the material was exposed to the action of boiling water for half an hour the adhesion of the linen layers to the rubber was not appreciably reduced.

In view of the importance of producing hose which shall satisfactorily meet the requirements of the German railways, these tests should prove of especial value not only to manufacturers of rubber goods, but also to the engineering profession generally.—*Engineering Magazine.*





AUTOMATIC PUMP-GOVERNOR AND RECEIVER.

In the steam-heating system of a building an automatic device should be provided, which receives the water of condensation from the radiator coils and pipes, controls the pumps, obviates the objectionable "hammering" of the pipes, and returns the water of condensation to the boiler while still hot. A device of this nature is made by the Creamer Steam Specialities Company, Jansen Hasbrouck, proprietor, of 126, Liberty-street, Manhattan, New York City.

The apparatus, as our sectional view indicates, comprises a receptacle (into which all water from coils, &c., drains) containing an open metal bucket, B, and a weight, W, twenty times heavier than the bucket, both hung from the ends of a lever fulcrumed at its middle. A second lever is fulcrumed at the weight end of the first lever, and is connected with the vertical stem of the steam-valve. As the water of condensation flows into the receptacle, and into the bucket, through the return pipes, the weight descends, pulling down the corresponding end of the lever, thereby opening the steam-valve and automatically starting the pump. When the water within the receptacle has been pumped out, the distribution of weight is reversed, the filled bucket now being twenty times heavier than the weight; hence, the weight is raised, the steam-valve closed, and the pump stopped. As the water again accumulates in the receptacle the bucket is buoyed up, and the operation begins anew.

The apparatus is now in use in many large office buildings and institutions, in connection with pumps of all kinds. In old and new buildings it will completely obviate all those objectionable noises in steam-pipes which are occasioned by the collection of the water of condensation. The returning of this water of condensation in its heated condition to the boiler is another of the advantages incident to the use of the device.—*Scientific American.*

THE JEWEL OF THE DEEP.*

Although many fine pearls are said to have been comparatively recently discovered in Arkansas, pearl fishing in the waters belonging to the United States amounts to little at present. But there was a time, many years ago, when the rivers, bays, and various other places on our coasts were explored for pearls with an eagerness that could have been aptly termed pearl fever. As a result of this quest of the jewel of the mollusc many were found; but they were, except in a few cases, of small size and no great value. One of the largest found was the "Queen Pearl," which was sold by Tiffany to the Empress Eugénie of France for 2,500dol.

Not being able to find pearls in paying quantities in his own waters, the enterprising American sought to force the mussel to produce the desired jewel by inserting into its mouth a foreign substance, around which nacre was to be deposited to make the beautiful laminated globules. An exquisite specimen of pearls so produced is seen in the Smithsonian Institution at Washington, where are so many interesting things that had their home in salt or fresh water.

This forced jewel is attached to the upper, or hinged portion, of one-half of a fresh-water mussel shell, which was taken from the Ohio River. The pearl is very large—about 2¼in. in circumference—and is of a very deep pink colour. To cause its production, the shell of the mussel was slightly opened and a piece of wax inserted. The mussel, unable to get rid of this foreign substance, "made the best of a bad situation," and began to surround the wax with nacre in order to prevent irritation, and ere long a beautiful pearl was formed.

Some years ago a company was formed for thus conducting a pearl-making industry; but while the oyster performed its part of the work—in a small way—the aggregate result did not pay for the time and money spent in the work. One man alone spent 20,000dol. in trying to make the pearl oyster of the Torres Straits manufacture pearls at his bidding. From last accounts he was still enthusiastic over the enterprise, but found it easier to put 20,000dol. into the mouths of molluscs than to get them out.

John Chinaman has successfully compelled the mollusc to work for him, as is shown in the Smithsonian collection of pearls, mollusc shells, &c. Here is seen a shell covered with shining nacre, under which are little metal figures of Buddah. The Chinese priests insert the diminutive, but crude, figures of their god into the oyster's mouth, and when they are covered with nacre, cut them from the shell and sell them to their superstitious followers, who believe the images to be of miraculous production.

The Smithsonian Institution possesses a most interesting collection of mollusc shells, embracing almost every variety, from the smallest to those that weigh several pounds. Among the latter are some pearl oyster-shells nearly as large as dinner-plates. One of these was brought from the pearl fisheries of Ceylon, and is an exquisite specimen, having its inner surface covered with an almost transparent coating of nacre (mother-of-pearl) that approaches the colour of burnished silver.

The inner portion of pearl oyster shells, as is well known, is used for making pearl buttons, knife-handles, handles and backs for toilet articles, and a great variety of other things. Before being ready for the manufactory they (the shells) have their backs ground down to near the nacreous material, when they are cut into required shapes and sizes and made ready for market.

When the old Spanish galleon sailed the waters of the far east, the only product of the oyster sought by them was the pearl. They carried home for the royal and the rich many beautiful specimens of the jewel of the deep; and not only the Spaniard, but also people of other nations for hundreds of years valued the pearl oyster only for its little glistening spheroid, which the Arabs say is made from a drop of dew that falls into the open mouth of the mollusc.

But when it was found that mother-of-pearl could be utilised for practical and ornamental purposes, the once neglected shell soon became of more value (in the aggregate) than the pearl jewel. And it is well for the pearl-fishing industry that such is the case. There are many instances where thousands of pearl shells were taken which yielded only a few small pearls. But sometimes a day's fishing will gather a small fortune in the latter.

One of the very old fisheries is that lying near the coast of Ceylon, from which a vast number of pearls have been taken. Other important fisheries are those in the Gulf of Persia, the waters of Java, and those near Japan, the Isthmus of Panama, and the mouths of the Rio de la Hocha, in South America. There are other places where pearl fishing is carried on, among them being some in the waters near the Philippine Islands (principally in the Sooloo Sea and around the southern group of these islands) and near the coast of Lower California and the Mexican Pacific coast to the Guatemala boundary. But the first mentioned have given the best and largest products.

In some of these pearl fisheries large areas are covered, those in the Merguian archipelago, in the government of Burma, comprising 11,000 square miles. Pearls are found there, but the main industry is in gathering pearl shells. For some time past the oyster-beds have been rented from the Government.

The pearl fisheries of Madras and Ceylon are inspected every year by a Government official, who permits the banks to be worked only when they are in good condition. The great fisheries of Ceylon are carried on from four to six weeks each season, which begins in March. At sunrise the boats are on the fishing-grounds, and the divers—two in a boat—begin work. They are let down into the water by a rope, to which is attached a stone weighing about 40lb., and after working rapidly for about two minutes, are drawn up for a breathing spell. Besides a basket for holding his catch, the naked diver takes down with him a pointed stick to be employed as a weapon of defence against sharks. With this and the knowledge that the shark-charmer above (there is one in each boat) is performing his incantations, he feels perfectly safe, and seeks the molluscs as long as he can hold his breath.

It is said that the most beautiful pearls are found in the Persian Gulf. No doubt it was from these waters came the pearl which Cleopatra swallowed in a glass of liquid. History says that this famous queen disposed of in that remarkable draught about 40,000dols., the value of the jewel. In a later day—during the reign of Queen Elizabeth—this costly example of Egypt's frisky queen was followed by Sir Thomas Gresham, who, to win a bet with the Spanish ambassador, that he (Sir Thomas) would give a more expensive dinner than the Spaniard, beat into a powder a pearl valued at nearly 75,000dols., and drank it in a glass of wine.

Pearl fishing is of extremely ancient origin; but notwithstanding this, it is carried on in most places after the method employed a thousand years ago.

RAILROAD SIGNALLING.

Progress in railroad signalling is indicated to a certain extent by the relative amounts of attention given to the various topics of discussion at the recent annual meeting of the Railway Signalling Club, held in Boston. The subjects introduced by the papers presented were: "Normal Safety v. Normal Clear Systems of Automatic Signals," by A. J. Wilson; "Progress in Signalling," by H. M. Sperry; and the "Possibilities of Three-Position Semaphore Signals," by Frank Rhea.

Mr. Sperry's paper on progress in signalling was an admirable review of the state of the art, and was suggestive in regard to recent improvements in constructive details which should find general use in the future. It was the best paper presented, and worthy of a thorough discussion, which it did not receive, but it developed the fact that the most important subject in signal practice is that of the proper colour for use at night on distant signals. The recent adoption of yellow for this purpose on the New York, New Haven, and Hartford R.R., and the fact that the meeting was held in Boston offered an opportunity for the members to inspect the colour under practical conditions, which was taken advantage of.

The result was a favourable impression upon most of the members. The best opinions seemed to favour the new plan. Objection was made that yellow was not sufficiently distinctive; this, however, was not a source of danger, because it was possible that the new colour would be mistaken for red under certain combinations of atmosphere and distance, but it was not likely that a red light could ever be mistaken for yellow. At short and even moderately long range, however, the distinction was sufficient, even if in doubt at a distance. The mistakes would therefore be likely to occur upon the safe side. This is the ground that we have taken in regard to the yellow distant signal light, and it was confirmed by the discussion.

It may therefore be said that the cause of the yellow light has gained ground. It is highly important that the colour should be exactly right, and that the glass should be made with extreme care. In connection with the shade of colour, it should be stated that Mr. C. Peter Clark, general superintendent of the N.Y., N.H., and H R.R., has found that the enginemen prefer a decided tinge of red in order that there may be no question of the doubt being on the right side in case of thick weather. The new colour has not yet gone through a winter, and it is possible that valuable experience may be had by viewing it through snow.

The first of the papers introduced the question whether block signals should stand at "danger" positions or at "safety" under normal conditions with the track governed by the signals unoccupied and ready for a train to proceed. To the enginemen there is practically no choice, because with both systems properly installed and in working order, they cannot see any difference. It was argued that the normal danger had two decided advantages. First, the signals were liable to freezing up in sleet storms, and it was safer to have them

held in the danger position, and if they stood normally at "all clear" they might freeze, and give misleading information of a dangerous character. Second, the signals are held at "all clear" by the battery currents, and there was an important economy in battery material and supplies in the normal danger system in which the batteries were only used while the signals were held at "all clear" for the passage of trains.—*American Engineer.*

WHY THE U.S. NAVY ADOPTED WATER-TUBE BOILERS.

THE reasons for adopting the water-tube boiler in the U.S. Navy are very admirably set forth in a paper by Admiral Geo. W. Melville before the Society of Naval Architects and Marine Engineers, in which the speaker first expressed his opinion that water-tube boilers are bad in principle, as a failure in a tube is followed by the opening of a fault, while in a fire-tubular boiler the pressure would continue to close a split tube; but on the other hand he considers that the value of their advantages has been sufficiently developed in the last two years to necessitate their use, if we do not wish to be left behind in naval design. In the fitting out of two ships of identical qualities, one with cylindrical boilers and the other with water-tube boilers, the latter will be somewhat the smaller and handier—will have less draft and will cost less, and the facility with which water-tube boilers can be removed or completely renewed without disturbing the decks of protected vessels is of itself enough to justify the adoption of water-tube boilers. The heating-surface has gradually been reduced from 3sq.ft. per horse-power against 2sq.ft., which is necessary with cylindrical boilers to 2·4sq.ft. of heating surface per horse-power. The writer dwelt to some extent on the failures of the water-tube boiler instead of showing only their good points, for in so doing he gets most information from them. He also stated that so far as he knows, there is not one failure that can properly be said to have occurred purely as a result of being a water-tube boiler. Admiral Melville heartily believes in water-tube boilers as compared with cylindrical boilers for navy use, and gives the following list of advantages: Less weight of water, quicker steamers, quicker response to change in amount of steam required, greater freedom of expansion, higher cruising speed, more perfect circulation, adaptability to high pressures, smaller steam-pipes and fittings, greater ease of repair, less danger from explosion; and it is evident that he considers the Babcock and Wilcox type as being specially favourable. He states the disadvantages as follows: Greater danger from failure of tubes, better feed arrangements necessary, greater skill required in management, units too small, greater grate surface and heating surface required, less reserve in form of water in boiler, large number of parts, tubes difficult of access, large number of joints, more danger of priming.

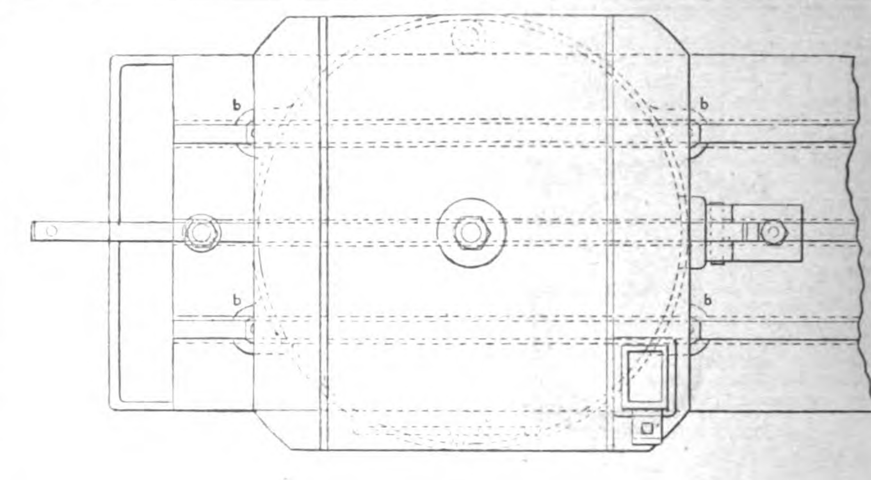
A DUPLEX MILLING FIXTURE.*

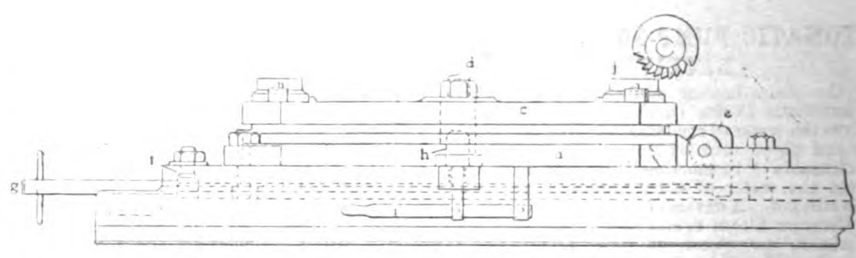
THE output of milling machines is frequently much below the actual capacity of the machine, on account of the time required to take the milled pieces from the fixture and put in others ready for the cut. This is more especially so when the work is cast or forged, requiring separate bolts and clamps for each individual piece, on account of unevenness.

The subject of this article is a fixture which was designed to avoid this loss of time. We call it a turntable fixture, for want of a better name, and refer to the drawing. *a* is the bed of the fixture, which is fastened to the platen of the machine (in this case a No. 5 Brown and Sharp, which has three slots) by the lugs and bolts, *b*; *c* is the table, which is fastened to *a* by the stud, washer, and nut, *d*, and adjusted to turn freely without shake. *c* has a groove turned as shown, to receive the end of clamp, *e*, which is in the form of a bell-crank lever; *f* is a T-bolt, drilled and tapped, and clamped in place by nut. The rod *g* is threaded at *f*, and continues to lower arm of *e*. *h* is a bolt with taper end, which is held in place by a spring, and fits in one of two steel bushings placed opposite in the table to serve as an index. *h* is operated by the lever *i*. *j* is the work to be milled.

When the cut is finished and the feed drops, the operator runs the platen back with his right hand until the work is clear, at the same time turning the rod *g* with his left, which releases the clamp *e*. He then draws the bolt *h* with left hand on *i*, and gives the table one-half turn, bringing the next piece of work into position to be milled, and runs it up to the cutter with his right hand, at the same time tightening the clamp *e* with his left, and throws in the feed.

He now has the time required to make the cut, in which to remove the milled pieces (the number of which will, of course, be determined by their size,





and capacity of machine), clean out the chips, and clamp in new ones.

If the operator is lively, or works by the piece, the time elapsing between the finish of a cut and start of a new one will be measured by seconds, and the increase output compared with a single fixture will be surprisingly large.

LANTERN SLIDES FROM DIAGRAMS, &c.

TO produce a passable slide it is absolutely essential that the ground should be free from fog, and that the lines must be of a good black tone, so as to give a good contrast. How to achieve this desirable end is the object of these short notes.

The diagram or map should, if possible, be specially prepared, having good bold black lines, and drawn on paper, leaving a good margin all round. This will give more even illumination, and enable the sheet to be secured to a support with the drawing-pins well out of the view. This support must be perfectly vertical, otherwise the lines will be more or less distorted. The camera should be set sufficiently far from the diagram as to allow a good margin within the lantern-slide mask, and this margin should be even all round—i.e., if the diagram is oblong the mask should be cut to suit.

The exposure necessary is a simple matter, if the following instructions are followed out. I personally prefer a bright day, but no sun shining directly on the diagram; and by giving a short exposure, and obtaining the necessary density by intensification, it is not a difficult matter to keep the lines from veiling over if a full amount of bromide is used in the developer.

When the negative is afterwards intensified, care must be taken not to spoil the clearness of the lines, for if any fog is there at the commencement, this process only intensifies it, which is fatal to success.

The making of the transparency from this negative is a simple matter, as, given clear lines and a dense ground, a full exposure can be given without fear of fog, and the ordinary hydrokinone developer will give a good jet black line, and leave the ground bright, clear glass. By printing the title on the diagram before the exposure it will greatly add to the attractiveness of the slide, as its meaning is at once apparent, and it also enables the slide to be quickly selected from the others. In all cases of this kind of work it will be as well to decide from the start to make them ask oneself, and it should, as before stated, be proportioned to suit the slide, though in the series of slides on one subject, it will be found advisable to have all the openings as near one size as convenient; hence the camera should be set to give this result when making the negative.

Before leaving this subject I would just remind my readers that, if they wish to preserve their negatives in a good condition, a coat of varnish will amply repay the extra trouble; but it must be very evenly applied, or else the streaks will be visible in the slide in the form of fog. I have made hundreds of slides in this manner, and shall be glad to help any who desire further information.—W. E. A., in *Photographic News.*

SMOKELESS POWDER AND BLUE GLASSES.

SEVERAL letters have appeared in the *Times* and elsewhere recently about the above subject, and the following may be of interest. Mr. J. H. Steward says:—As many persons are under the impression that violet-coloured glasses will enable one to locate the flash of the explosion of smokeless powder from a rifle, I beg to inform you that, having experimented with different-coloured glasses during the last Bisley meeting, I could obtain no satisfactory results. I selected ranges varying from 50 to 800 yards and observed from a position that enabled me to obtain a lateral view of the flash. The best results were obtained with the cobalt-coloured glasses, but in no case could the flash be detected better than when looked at through an ordinary field-glass without coloured glasses. At ranges beyond 400 yards it was almost impossible to detect the flash. Without coloured glasses the bluish-tinted smoke could be readily detected at all ranges. This small thin cloud proceeding from the discharge was, however, only plainly visible when several rifles were fired at once. Owing to the rapidity with which the smoke was dissipated, one had to look with very close attention. With regard to the discharge from guns, the result might be as stated by Mr. Lascelles-Scott in his very interesting letter. I have made no observations with this weapon. A well-known general, however, informed me that he had no difficulty in locating the flash from a gun with the aid of the ordinary optical adjuncts.

Mr. Alfred H. Allen, of Sheffield, writes:—I observe that your correspondent, Mr. W. Lascelles-Scott, suggests that a cobalt-blue glass or other blue medium should be employed with field-glasses for observing the position of guns firing smokeless powder. Mr. Scott's ingenious proposal is open to some serious objections. It is based primarily on the assumption that smokeless powder contains picrate of potassium, and the visibility of the flame is ascribed to the presence of potassium in that or other form. Unfortunately for the success of Mr. Scott's ingenious proposal, smokeless powder, at least as used in the British service, contains no potassium either as picrate or in other form, and therefore the proposal would not be applicable to it. Secondly, if the Boer or other powder contained a potassium compound it would not be smokeless, and therefore the position of the guns firing it could be localised without the use of blue glass or similar contrivance. It is to be regretted that Mr. Scott did not think of this evident fact before making his proposal public. I may add that I have just viewed burning cordite through cobalt-blue glass as suggested by Mr. Scott, and could find no evidence of

the presence of potassium. The flame is far more visible without the use of blue glass than with it.

Mr. Frank Horridge: May I submit to you the following as a possible explanation of the contradictory views on the subject of smokeless powder and blue glasses? First, the Boer powder is probably a mixture containing a potassium compound, and does give off a slight amount of smoke, which one of your correspondents says is essential, and which the other says he has seen with powder used at Bisley of the smokeless kind. Secondly, the flash is not a true violet, but a blue-violet. Hence bluish or blue-violet glasses, preferentially the former, should be used to exclude the rays of sunlight. If you were to use pure violet glasses you would exclude the bluish rays of the flash, and under these conditions it is not surprising that violet glasses should have been found to be a failure. I think all will now agree that the sooner this matter is put to a practical test the better.

THE ALLOTROPIC VARIETIES OF IRON.

In order to explain certain peculiarities of steel, M. Osmond and others have been led to assume the existence of two allotropic modifications of iron—viz., Alpha iron stable at ordinary temperatures, and Beta iron stable at high temperatures. In a recent communication to the Paris Académie des M. Galy-Actié describes some experiments, which tend to confirm the hypothesis noted above. The metal used by M. Galy-Actié was almost chemically pure iron, carbon was totally absent, and there was only a trace of phosphorus. The iron was drawn into wire 8 millimètres (0·315in.) in diameter, and this wire was then cut up into 1,000 small cylinders 13 millimètres (0 51in.) high, which were annealed at 1,000° Cent. (1832° Fahr). These cylinders were then compressed, and a curve obtained showing relation between the compression and the the pressure producing it. The specimens proved very homogeneous; crushing commenced at a load equal to 18 kilogrammes per square millimètre (11·43 tons per square inch), there being a well-marked breaking-down point. The permanent set under this load was $\frac{1}{10}$ millimètre ($\frac{1}{254}$in.). If, after the set had appeared, the load was relieved and immediately reapplied, crushing only recommenced when the highest pressure previously attained was reached, and the new stress-strain curve exhibited no breaking-down point. If, however, some hours were allowed to elapse before reapplying the load, the cylinder would support without fresh crushing a load considerably in excess of the highest previously applied; and when finally crushing did occur, the event was characterised by a well-marked yield-point. It was thus possible to raise the yield-point of the material far above its initial value. All cylinders annealed after heating to a temperature exceeding 850° cent. showed a well-marked yield-point, but if quenched from this temperature and then tested at once, the yield-point disappeared, the stress-strain curve becoming uniform throughout. If, however, a certain time was permitted to elapse before testing the specimen, the yield-point would make its appearance, and this recovery of the metal to its primitive condition could be hastened by applying quite a moderate heat. If the metal was quenched from a temperature below 850° cent., the yield-point was always present. M. Galy-Actié interprets his experiments as proving the existence of the two allotropic modifications of iron. The Beta iron can be produced at ordinary temperatures, either by mechanical deformation or by quenching, but is essentially unstable, and gradually changes into alpha iron.—*Engineering.*

Guide to the Constellations.—A new and enlarged edition of "An Easy Guide to the Constellations," by the Rev James Gall, has just been issued by Messrs. Gall and Inglis, Paternoster-square and Edinburgh, and will be found useful as a present to young folk. The maps and the atlas render the subject clear, and the little work is a capital "stepping stone" to the larger atlases.

The partnership that has subsisted for some years between Messrs. Perken and Mr. A. Rayment (under the style of Perken, Son, and Rayment), was determined by effluxion of time on the 31st ult. Messrs. Perken will continue to carry on business at the same address under the style of Perken, Son, and Co., and we have no doubt will give the same satisfaction in their "Optimus" specialities and general business as they have done for so many years past.

An electric-transmission plant has been put in operation at Allegan dam, in Michigan, the current being conducted to Kalamezoo, a distance of 22 miles. A pressure of 25,000 volts is used. It is intended to increase this to 40,000 volts, if experience shows that the climate will permit. An extension to Battle Creek and Jackson, Michigan, by the end of the year will give the largest power-transmission line in the world—90 miles.

SCIENTIFIC NEWS.

FINLAY'S comet, discovered by Mr. Finlay, of the Cape of Good Hope, on Sept. 26, 1886, is due to return to perihelion next month. It has a period of about 6½ years, and was observed in the summer of 1893. M. Schulhof thinks that the chances of its being observed next month are very slight, but in 1906 he calculates that the comet will be very brilliant, and will approach the earth about the middle of August. Looking so far forward as 1910, the comet will make a near approach to Jupiter, and will thus afford an opportunity of estimating the mass of the giant planet.

The *Bulletin* of the Société Astronomique de France for January, 1900, contains, amongst other interesting articles, "Les Léonides," by Mlle. D. Klumpke; another on the eclipse of the sun on May 28 next, by M. A. de la Baume-Pluvinel, with charts; and one by M. C. Flammarion, with illustrations, entitled "Dessins de la Lune vue à l'œil nu." The 20th century question is touched upon in a note by M. Camille Saint-Saëns, in which he says: "Il s'ensuit que lorsqu'il s'agit de l'âge d'un être vivant, homme, animal, ou plant, le chiffre I. signifie une année qui finit, tandis qu'en chronologie le chiffre I. signifie une année qui commence."

The *Journal* of the British Astronomical Association (Jan. 13) contains the reports of the directors of the lunar section, the double star section, and the variable star section; some interesting correspondence on the apparent enlargement of heavenly bodies near the horizon, papers on the double canals of Mars, and the usual collection of notes. Particulars as to the proposed expedition to Spain and Algeria for the eclipse of May 28 are given, and (as a loose slip) wave-length scales for eclipse spectra.

Prof. W. Harkness has retired as rear-admiral, on reaching the age of sixty, from his position as astronomical director of the Naval Observatory of the United States. Prof. S. J. Brown has been appointed his successor. He was formerly at the Observatory of the Naval Academy, Annapolis.

Some remarkable meteors appear to have been observed recently, judging from notes in various papers. A correspondent, writing from Stocksfield-on-Tyne, says that on Jan. 7 he saw a meteor which "left the zenith and traversed the heavens in a southward direction, ending its course by exploding similar to a rocket. The path of the luminous body was marked by a long stream of light. The meteor and its phosphorescent train were visible for the space of two or three seconds." A "daylight meteor" was seen by another observer from Beckenham, Kent, at about 3 p.m. on Jan. 9. It was a brilliant meteor about 60° above the horizon, and in a general direction from a little to the north of west to the south of east. Although the sun was shining brightly at the time in a cloudless sky all over, the meteor was very distinct and apparently of a large size. It comprised a head, a brightly glowing body, which as it passed across the sky appeared to throw off, as it were, flakes of flame. The meteor, leaving a trail of bright light behind it, vanished, as it seemed, quite low down and very little above the horizon. This meteor seems to have been noticed by several persons, for we learn from a paragraph in the *Times* that several correspondents have written about a very bright meteor which was seen between 2 and 3 o'clock p.m. on Tuesday, Jan. 9. Mr. H. H. P. Bouverie writes from Glynde Place, Lewes:—"While shooting here to-day I saw a brilliant meteor which started from near the moon, that was quite bright at the time; it travelled for a short distance towards the north-east, and left a marvellously luminous path of white light. The time of its appearance was as near 2.55 p.m. as possible. I never heard of such a thing being seen in broad daylight." "A. C. E. S." says:—"At 2.55 in brilliant sunlight a remarkable meteor was seen by a party of five from Reigate-heath Golf Ground. The course of the meteor was south to north, and it traversed a considerable portion of the heavens. In appearance it resembled a kite with a tail of a luminous white colour. It was visible for about a second." The Rev. R. Hudson also writes, from the Drive, Brighton:—"The colour was brilliant white, like an incandescent gas light. There was a nucleus and tail of considerable length. The altitude was about half that of the moon, which was visible at the same time. The sky was cloudless and blue, and the sun was shining brightly. The general effect was that of the falling stick of a rocket, and, indeed, my first impression was that it was a peculiar daylight rocket, but a moment's consideration of the direction of flight convinced me that it was a very remarkable meteor."

A remarkable rainbow, too, appears to have been observed by several correspondents on Jan. 11. Mr. C. H. Swinstead writes to the *Standard* saying he was in Venice on the day in question, and it may be useful to those who study atmospheric phenomena to know that the strange appearance was visible there as well as in England. "What I observed was as follows:—At about 11 a.m. (Central European time) I happened to look at the sky, which was clear of clouds in all the upper regions, at least as far towards the horizon as the level of the sun, and I saw a brilliant rainbow against the clear blue. The arc was, perhaps, one-third of a circle, with its centre at the zenith, and its distance from that point about 15°. This bow had its convex side towards the sun. At the centre of the curve another fainter bow touched (or rather overlapped) it back to back, so that a pair of horns were visible at either end. This second bow had its apparent centre in the sun. At half-past eleven a third bow was also visible about half-way between the sun and the second bow and concentric with it. This was quite faint. At this time a small patch of vivid prismatic colour was also to be seen in the south-west, where the sun's rays darted through a gap in a little cloud. This was at a level of a few degrees below that of the sun. At half-past twelve the forked form still persisted, but the others had disappeared."

Many microscopists will regret to hear of the death of Mr. W. T. Suffolk, in his sixty-ninth year. He was treasurer of the Royal Microscopical Society for many years, and did much useful work in connection with the science.

The *Athenæum* says: Geologists will recall the name of an old correspondent in Edwin A'Court Smith, who died at his cottage at Gurnard, near Cowes, on Jan. 5, at the age of 89. Though possessing none of the advantages of education or scientific training, he was a born naturalist and antiquary, and of his own initiative, unaided save by his own hands, he carried on protracted and laborious excavations on the foreshore of the Solent, unearthed a Roman villa and various antiquities, and formed large fossil collections, whence the Natural History Museum and other museums have been enriched with rare specimens. Meanwhile, the fortunate discoverer endeavoured to support his family on the produce of his garden! Mr. A'Court Smith—he was tenacious of the noble strain—was a pathetic illustration of natural gifts crippled by circumstances. When his sight was dimmed and his natural strength abated by the burden of years, his enthusiasm for science never failed. His laborious unrewarded life belongs to the romance of science, and a stern, inexorable romance it is.

Another naturalist who, without the advantages of education, became widely known for his contributions to entomology and other branches of natural history, died the other day in Dumfries. Mr. William Lennon, who had reached the age of 81, besides much other work, discovered some half dozen beetles new to Britain, and a few new to science. For many years he was an attendant at an asylum.

At the Royal Institution to-morrow (Saturday, Jan. 20) Sir Hubert Parry, Mus.Doc., commences a series of lectures on "Neglected Byways in Music."

The annual general meeting of the Association of Technical Institutions will be held on Wednesday, Jan. 24, at Mercers' Hall, London. The president, Earl Spencer, K.G., will be in the chair, and Sir Swire Smith, the president-elect, will deliver an address.

The fifty-third annual general meeting of the Institution of Mechanical Engineers will be held on Friday, Jan. 26, when the chair will be taken at 8 o'clock by the President, Sir William H. White, F.R.S. The annual report of the council will be presented to the meeting. The election of the president, vice-president, and members of council, and the ordinary election of new members, will follow. The paper to be read and discussed is "Water-Meters of the Present Day, with Special Reference to Small Flows and Waste in Dribbles," by Mr. William Schönheyder.

It is announced that the bacteriologists of the

Liverpool School of Tropical Diseases have discovered the microbe of pink-eye, a disease which is the cause of great mortality amongst horses.

A "rare fossil" has, it is reported, been discovered at Harrogate in the thick shales that have been intersected in the formation of the Corporation's new reservoir at Scargill, about four miles west of the borough. When this specimen was submitted for naming to the British Museum authorities, they expressed an earnest wish that it might be given to them to enrich the national collection, so that there are now two specimens of this rare species in the British Museum, another being in the Woodwardian Museum, at Cambridge. As most geologists know, the genus of the Nautilidæ extend in range of time from the Lower Silurian beds to the present day. "The species under notice belongs to the carboniferous limestone; and the fact of its being found deeply imbedded, as an imported fossil, in the shales of Scargill throws a new light on the true character of these shales." Strange to say, the report does not mention the name of the "species under notice."

The Victor Meyer memorial lecture will be delivered to the Chemical Society on Thursday, Feb. 8, at 8.30 p.m., by Prof. T. E. Thorpe, president of the society.

At a meeting of the Royal Botanic Society last Saturday, the attention of the Fellows was directed to a curious stem of the *Testudinaria elephantipes*, or "elephant's foot," grown in the society's gardens. The stem bears a curious resemblance to the elephant's foot, but is remarkably light. The genus Testudinaria seems to be confined to South Africa.

The fish-hatching experiments at the Crystal Palace are reported to be very successful, and large numbers of the Salmonidæ have been obtained.

The new fish hatchery of the Fishery Board for Scotland at Bay of Nigg having been completed, the place is now being stocked with fish for the purpose of studying their nature and habits. The steam trawler chartered by the board returned the other day after a successful cruise in the Moray Firth, Dornoch Firth, Lybster Bay, and waters within the three-mile limit, there being no restrictions in the case of a vessel engaged by the board for the purpose of taking fish for scientific purposes. About 150 plaice, together with a number of haddocks and other fish, were secured, and were well preserved in the special tanks provided for the purpose, being deposited in the hatchery tanks in good condition. Another trip is to be made by the trawler, so that more fish may be obtained for the hatchery, where it is proposed operations should be carried on in a much more extensive scale than at Dunbar, from which the hatchery has been transferred.

It is to be hoped that the departmental committee appointed by the President of the Board of Trade to inquire into the rules relating to the granting of patents will arrive at some definite conclusions, and settle all the vexed questions. The official terms of the reference are—"To consider various suggestions which have been made for developing the benefits afforded by the Patent Office to inventors, and report." The committee is to consist of Mr. F. J. S. Hopwood (chairman), Mr. Edward Carpmael (president of the Chartered Institute of Patent Agents), Mr. C. N. Dalton (Controller General of Patents), Mr. J. A. Kempe (deputy chairman of the Board of Customs), and Mr. S. E. Spring Rice, of Her Majesty's Treasury; Mr. Arthur Neeves, of the Board of Trade, to be secretary of the committee.

The members of the Institute of Marine Engineers have been recently engaged in an interesting discussion on the circulation in water-tube boilers, which should be of use to makers. The author of the paper on which the discussion was based (Mr. Halliday) said that his advice to makers was to decrease the speed of circulation in water-tube boilers—not to increase it. In his experience the water-tube boilers in which the circulation was slow lasted twice as long as those in which the circulation was fast. Mr. Halliday contends that a high rate of circulation does not give the best results. The discussion was adjourned to Jan. 22, and when published in full should be of much interest to makers of quick-steaming boilers.

It is stated that the torpedo-boat destroyer *Viper*, built to the order of the Admiralty by the Parsons' Marine Steam Turbine Co., Ltd., in her second preliminary trial attained the high speed of 35·5 knots—a mean of four runs on the measured mile, giving 34·8 knots. That speed is considerably above the contract (31 knots), and the fastest run, it will be noticed, is extraordinary, rather beyond the anticipations, we suppose, of those best acquainted with the capabilities of the steam turbine.

Another roller-boat is being built in Canada—where is not mentioned. This vessel is a cigar-shaped craft, about 30ft. in length. The screw consists of a cylinder about one-half the length of the boat, situated in the centre, and passing entirely round the hull proper. This cylinder is supplied with fins, or wings, running diagonally round from one end to the other, and their rotation gives motion to the hull. The keel, connected at both ends with the hull proper, hangs below the revolving cylinder. The description does not seem to be very clear, and looks like a repetition of the previous accounts.

Cellulose packing has been used for stopping leaks caused by shot-holes in warships by the French and by Americans, because the material swells greatly when brought into contact with water, and therefore does well as a "cork," or for caulking. It is reported, however, that the cellulose will not preserve its properties for any length of time, but degenerates and becomes a "nuisance," from the sanitary point of view.

Some railway experts have recommended the use of yellow signals to indicate caution, and it is stated that they have been adopted on some railways in the United States and Canada. There is much difference of opinion as to the best colours for railway signals, and there is much doubt about yellow. It appears that the majority of people can see the "colour" in daylight for longer distances than any other; but some see it as red at night. That would not detract from the value of yellow, in one sense, as "red" means "danger" on all lines in this country; but the use of yellow might lead to quite unnecessary stoppages.

What is described as a new method of making oil-gas has been shown to a number of civil engineers and others interested in automobile and tramway traction. It is understood that a company is bringing out the invention, which is of French origin, in this country. It is thus described: "The 'gas fountain' consists of a plain tin oblong canister, with two tubes projecting from the top. The box, packed with a highly porous specially-prepared wood, is charged with a hydrocarbon liquid, such as petroleum. This is entirely absorbed by the wood. By means of a siphon arrangement of the tubes, air passing through the oil, held by the fibrous absorbent in a finely-divided state, is automatically turned into gas, the uses of which for motor, lighting, heating, and all other purposes to which gas can be applied were demonstrated.

A large portion of the "Stretton Collection" railway rails, drawings, and relics which was sent to the Chicago Exhibition of 1893 has recently been returned to this country, and we are glad to know that the owner has presented the whole of this interesting collection to the nation for the South Kensington Museum. Already a very considerable portion of this valuable collection is on view, and further instalments will be shown as soon as space can be arranged and the required frames constructed. The Science and Art Department has also commenced to sell to the public photographs of the locomotive sheets at a cost of eighteenpence each. When the complete collection is in position, it will form a perfect record of British locomotive progress. Mr. Clement E. Stretton, our readers will remember, has been a contributor to the ENGLISH MECHANIC for over thirty years past.

So far as I have encountered them, says Prof. Rostwell, a characteristic of great men is that they have time. They are not in a hurry; their work doesn't boss them, but they boss their work. They don't act as if every minute you stayed was valuable time lost to them; they don't fret and fidget. What time they do devote to you appears to be time that they can spare, and take things easy in, and be comfortable. The work seems to be incidental, and it seems as though they could turn to it when the time came and get through it with ease; and they always seem, besides, to have strength in reserve. It is certainly a characteristic of the great man that he has time.—*Popular Science*, N.Y.

LETTERS TO THE EDITOR

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]

All communications should be addressed to the EDITOR *of the* ENGLISH MECHANIC, *332, Strand, W.C.*

*** *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks; a vice from whence great inconveniences derive their original." —*Montaigne's Essays.*

A METEOR—A POINT ABOUT THE CENTURY WHICH HAS BEEN MISSED!

[43218.]—On Tuesday, Jan. 9, at about 2.30 p.m., I observed from Warlingham a very conspicuous meteor. It passed from about S.W. to N.E., and vanished almost under the then position of the moon. It was, I suppose, speaking roughly, about 45° from the horizon. Its line of movement was curved downwards. The sky was absolutely cloudless, and there was bright sunshine, so that the meteor must have been a very brilliant one. Its colour was very white, reminding one of burning magnesium wire, or, as another person who saw it said, like an electric-arc light. It was of the usual form, rounded in front, and tapering to a tail, leaving a few sparks behind, but no cloud. I hope others of your readers will have seen it.

May I say one word, my first and last, on the vexed subject of the century? It is this: both parties are in a degree right. Your correspondent W. F. Stanley is absolutely unanswerable as to the proper numbering of the first year of the first century. It is due to the blundering old monk (I forget his name) who, in the 4th century, arranged our chronology, that the first year was marked A.D. 1, and the previous one B.C. 1, whereas it is obvious to everyone who sees as clearly as your correspondent W. F. Stanley, that the two years should have been B.C. 0, followed by A.D. 0. "There never was a year 0" says "F.R.A.S." No! *But there ought to have been. The ordinal number is always one in advance of the cardinal, in reckoning time*, and when Our Lord was "in His first year," He was 0 years old, not 1. Thus, as I said, both parties are right. Those who say Jan. 1, 1901, commences the 20th century are historically right, owing to the original blunder: but those who say 1900 commences the century would be right, if the years had been properly numbered to start with. As a matter of fact, the present year is really 1899—that is to say, the Incarnation (if it began, as supposed, at the commencement of the first year of the first century) is now only 1899 years old. If we are not to reckon the first year of the first century as A.D. 0, the second year as 1, and so on, we are clearly wrong to call the years commencing with 18— (say, 1850) as the 19th century. The principle is precisely the same. If the matter were of importance, the only solution would be to make the years ending in 00 commence the centuries, and to reckon the first century as having only 99 years.

Farleigh Rectory. **F. Bennett.**

METEOR—THE ANDROMEDA NEBULA—THE LUNAR SEAS.

[43219.]—The meteor seen by Mr. Parker on Jan. 9 was also seen here, although not by the writer. A friend of mine, unversed in astronomy, told me on Tuesday evening (Jan. 9) that he had seen a yellow meteor that afternoon some time between 2.50 and 3 p.m. It shot from the right-hand side of the moon downwards, disappearing under the moon. It is to be regretted that he is unable to give fuller particulars. He estimates its duration at between three and four seconds. I had not intended to make any note of this; but I do so now, as it corroborates letter 43195.

I would venture to point out a little slip, evidently unintentional, that Mr. Lattey has made. In his excellent article, on p. 484, he states that the Andromeda nebula is "a colossal maelstrom of glowing gas viewed almost edgewise . . ." and that "the entire structure is a vast mass of vaporous matter partially condensed into a fluid or viscous condition." I was always under the impression that the aforesaid nebula was stellar. Proctor, in "Half-Hours," informs us that the spectrum is continuous from blue to orange, and there is no indication of gaseity. G. F. Chambers, in the "Story of the Stars," sums it up: "This object is, however, probably stellar, . . . certain it is that it is not gaseous."

Without endeavouring to propound any new theory as to the probable constituents and com-

position of the lunar seas, I would suggest that, whatever the cause, it is identical with the phenomenon of the darkening of Plato's floor, and also with the more conspicuous shadings on the floors of some of the other ringed plains—Schickard, for example. The theory put forward by the writer of letter 43197 (p. 494) is not, I fear, so original as he fondly imagines. "The actual surface temperature of the full moon is estimated by Mr. Very to be something approaching 206° Fahr." (see p. 460 of the "E.M.," Jan. 5, 1900). This would be more than enough to fluidise the rays, were they constituted as "Mark" supposes.

Earlsfield, S.W. Silverplume.

THE MOON AND THE WEATHER.

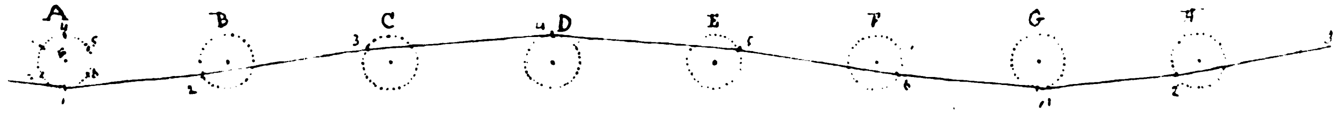
[43220.]—THAT the quartering of the moon regulates the weather (letter 43148, Dec. 29, p. 450), is a groundless opinion. The result of my observation is that changes have more frequently occurred at an octave—a mere chance. The real influence of the moon may be considered synthetically, by starting from our planet being considered, hypothetically, as a sphere of gas, then revolving it axially, with the effect of an equatorial protuberance. The effect of the sun's attraction being then introduced, the gaseous sphere will be altered in form to a sort of bi-semi-ellipsoid. That is to say, the half presented to the sun is of greater eccentricity than the other—egg shaped. The major axes being directed towards the sun do not partake in the revolution of the general mass, and the protuberances may be regarded as tidal, two tides in one revolution, the tide nearer to the sun being very slightly higher than the opposite one. Then the orbital motion is to be considered to be communicated to our planet (gaseous at present) with its axis adjusted to the obliquity with the Ecliptic, affecting the diurnal tides, with a motion parallel with the Equator, and also north and south, to and fro, annually. Such, the elementary conditions of the solar tide, obtain "mutatis mutandis" in regard to the moon, which complicates by producing other tides, more variable, and of greater force.

Assuming, hypothetically, that on any day it is equinox at noon, the earth at perihelion, moon at perigee, with their orbital major axes in a line with the sun, the combined tides would form the highest possible tide. At a point on the Equator, the next instant, both the sun and the moon acquiring declination, the two tides would proceed separately, and after any interval would be vertical at different points, which could be assigned by calculations relative to the positions of the several bodies; but no two points would be precisely circumstanced alike at the same instant, except after a very long interval, such as the Sothic period.

A portion of the gaseous earth, upon being condensed to water, other conditions arise, and another portion condensed to a solid consistency, further conditions arise. If the solid be of uniform spherical surface covered evenly with water, the air at the Tropics, heated and evaporated water would rise; cold and heavier air from the Poles would press towards the Equator to occupy its place, currents northward and southward would be generated, which would be deflected somewhat spirally by the diurnal revolution. And regarding the heated atmosphere at the Tropics as a cylindrical annulus, or sleeve encircling the earth, the position whereat the sun is vertical being heated most, the temperature diminishing gradually, easterly and westerly, and such sleeve being considered as consisting of a multitude of filaments or minute streams of air (with water vapour) moving in a Polar direction, parting with heat to the colder substratum, and in their progress conforming to the curvature, the most heated streams passing on the one or the other side, or between, the solar and lunar tides varying according to their several positions indicate "mixings" difficult to trace or describe. Moreover, the surface of the earth is not uniform. Land, seas, rivers, mountains, and valleys contribute to produce eddying currents and winds, to prevent weather forecasts being more than local.

Science has sought from the barometer evidence of an atmospheric tide, *overlooking* that air is an *elastic* fluid; the attraction of the moon over an area diminishes its weight, and the barometer would *fall*, not rise, but the lateral pressure effects equilibrium.

Letter 43152 (p. 452). Newton did not profess to account for "gravitation." He showed that its operation was in accordance with geometrical principles. The theory of gravitation explains why the moon does *not* always present the same face to us ("Libration"), and accounts for duplex tides, but not by "repulsion." The annexed diagram illustrates that, although the orbit of the moon is round the earth, its real path in space is a sort of elongate S, or slightly wavy from a straight line. The orbit A is greatly out of proportion in order to be clearer; the true orbit could scarcely be shown in so small a diagram to scale. The points 1 to 6 represent equal divisions, with their several places in a lunation A to G. M. O.



THE MOON AND THE WEATHER—HYGROSCOPES.

[43221.]—IN reply to "S. R.," the point of Prof. Angot's argument I take to be this: Different, or opposite, weather at the same time in two different regions, is not a sufficient reason for denying the possibility of lunar influence on weather; for both kinds of weather might be due to the same cause—viz., displacement of zones, or areas, of high pressure by the moon. Suppose—e.g., that with one position of the moon we found a tendency in a high-pressure system to take a more southerly position, A, and with another position of the moon to take a more northerly position, B, it is easy to see that two places, one in A, the other in B, might have, with the same position of the moon, the one a high barometer (with its associated weather), and the other a low barometer (with its weather). Similarly, with the course of rain-bringing depressions, which is largely ruled by the position of high-pressure systems: they might at one time take a course in more northerly latitudes, and at another in more southerly, and two regions might be oppositely affected accordingly. Some evidence of such lunar influence has been adduced by able meteorologists, and whether it is to be thought conclusive or not, it may seem sufficient to many of us (as against the dogmatic rejection of lunar influence) that a high authority like Angot considers the thing as at least within the bounds of possibility, if not even probable.

There are two mental attitudes in this controversy which it seems well to distinguish. One is that of the man who says: "It is preposterous to suppose the moon has anything to do with weather. This old popular notion has been thoroughly exploded. We know exactly what the moon can, and what she cannot, do. We know that her reflected heat is infinitesimal, and that any tidal influence she has on the barometer is so small, and so continually masked, that the effect of it on weather is virtually *nil*.

We may also dismiss the idea of electrical influence. If one man proves that the new moon brings rain, another proves exactly the opposite, and the evidence, as a whole, is a tissue of contradictions. Weather is a local thing, and how can one and the same moon produce opposite weather in different places? The subject has been thoroughly investigated, and we may consider that the last word has been said on it, and lunar influence shown to be an absurdity."

To people who talk in this way, it might be appropriate, if not sufficient, to point out that we really don't know everything about anything, or to say, as some eminent man (was it Cromwell?) once said, in a fiercely-wrangling assembly of Scotch divines: "I beseech you, brethren, to think it possible that you may be mistaken." It is fatal to close a subject as being thoroughly understood; and the history of science is full of cases in which those who did so have been stultified by some fresh revelation of the truth as it is in nature. It is only the other day we thought we knew all that is in the air; when, lo and behold, Argon turns up, and upsets all the textbooks.

We might go on, however, to argue that nobody at present knows very much about the causation of those movements of high-pressure systems; and we are certainly not in a position to say confidently that such cosmic influences as the moon, or the cyclical variation of sunspots, has nothing to do with them, especially as not a little is to be said for the *à priori* probability of such effects. But there is the further consideration that not a few serious meteorologists in these days are apparently not deterred by loud assertion that the subject has been finally closed from offering evidence of lunar influence to the great academies of science, and said academies think it worth while to publish their researches: witness the papers of Garrigou-Lagrange, Poincaré, and others in France; Ekholm and Arrhenius in Sweden, and so on. Nor should we here forget that high authority, "F.R.A.S.'s" lately repudiated friend, Prof. Hazen, who leans to the conviction that the moon determines how many thunderstorms we are to have. All this does not, of course, prove that the moon influences weather, but it shows that it is our duty to keep our minds open to fresh light on the subject; and it is chiefly for this I have been arguing.

This brings us, indeed, to the second attitude to which I referred, where one says: "I have studied the evidence adduced for lunar influence on weather, but I am not thus far convinced by it. I think such influence neither impossible nor improbable, and even if it seemed improbable, I do not forget that the improbable in science has often been demonstrated to exist; but I must await further evidence before I am convinced." Such a position we can all respect, and may even sympathise with.

With regard to "F.R.A.S.'s" last letter, I should be sorry to dispute his assertion that he possesses the "judicial quality" of mind. I only say that he has an unfortunate way of hiding it at times.

As to the "simple hygrometer," I am quite ready to agree to "S.R.'s" substitution of "hygroscope." Indeed, I used the former word loosely, and as perhaps better understood. Having experimented a little with the instrument, I have noticed the different quality in strings. But with some the pointer has gone round the greater part of the circle at least, which is, I think, a considerable measure of sensitiveness. A. B. M.

TELESCOPICAL—TO MR. CALVER AND "F.R.A.S."

[43222.]—MR. CALVER'S experience is so great as compared to mine that I fear I can add but little information to what he himself possesses; however, I will try to answer his questions.

I have used eccentric stops on a reflector, but do not remember to have ever tried one of the exact pattern that he describes, as the opening was always arranged to clear the central mirror. I have great doubts whether even the keenest-sighted observer could detect anything of the aberration in question with mirrors of ordinary proportions. If we take as an approximate rule that the focal length in feet shall be three-fourths of the speculum's diameter in inches, the amount of aberration appears to work out to an almost inappreciable quantity. Even in making this calculation I cannot help feeling that there is some uncertainty whether the usual mode of working does not exaggerate the real amount.

As regards "cast versus wrought" glass mirrors, if we adopt as a standard that the thickness is to be one-sixth of the diameter (as he used to recommend), Mr. Wassell's preference for rolled plate could obviously only apply to comparatively small mirrors. I remember his telling me that in cast discs he used to find soft patches which rendered accurate working practically impossible. He also noticed that the effect of ribs at the back was to destroy the homogeneity of the front face. I used to think that the best form would be that of a thick plano-convex lens, with the plane side hollowed out to the required curve as a mirror; the support being a central one. Practical experience, however, leads makers to prefer a plane surface for the back.

It may appear rather an absurd suggestion, but it has sometimes crossed my mind that bicycle balls (which are now made with such marvellous accuracy) might possibly be employed to support a large mirror, and so reduce to a very small amount the "sticking" that Herschel refers to, and which he used a sling to obviate.

I see "F.R.A.S" refers in his letter to length of focus of a telescope in proportion to aperture, though "from 30 to 60 times" seems rather a wide difference. His remarks refer primarily to photography, but the elder Herschel makes allusion to this matter without, however, dealing with it practically. I presume mechanical considerations of working the curves, have mainly fixed the proportion in both reflectors and refractors; but, perhaps, "F.R.A.S." could state whether, from purely optical considerations, there is any actual "best" proportion between aperture and focal length. The problem is also one that I am sure "H." could attack with advantage to both makers and users of telescopes. A. S. L.

WHERE IS THE IMAGE FORMED?

[43223.]—MR. NAYLOR and myself appear to be arguing the question from different standpoints: Mr. Naylor from a purely optical stand, from the eye outwards, for so alone can I understand the theory of diverging rays: but diverging rays are incapable of forming a reflected image of the source of those rays, be it a point or an assemblage of points—a line. Allowing that a point has dimensions, as a needle-point, we shall find it difficult to bring it to the test of measurement, but the rays emanating from it will follow the same laws as the

rays from a line. Here we agree. It sends out divergent rays, but the rad. vec. of rays which forms the reflected image may be considered as a bundle of parallel rays; those diverging from this bundle are lost to the eye or only taken cognisance of when reflected by objects around.

I have considered the matter as intimately connected with the question: What is light? And in seeking an answer to this, it is most convenient to trace the vibrations from their source till they enter the eye on their way to the place where they are modified into the phenomena of sight. Amongst the myriad sources from which, direct or reflected, an eye receives light-vibrations, the sun is a convenient one to deal with. A globe of some 800,000 miles diameter is sending vibrations diverging in every direction. I direct my eye towards it, protected by a dark glass, which certainly has no power to focus divergent rays, and the same holds good if I examine its reflection from a mirror, and I am conscious of a bright disc which subtends an angle of about 32 minutes, and seems to be about 9in. diameter; in fact my eye is at the apex of a vast cone of light vibrations, which, entering the pupil, reach the area of the yellow spot, and with this my diagram agrees.

Mr. N. acknowledges that "anything that applies to one point will apply equally to all points of the object"; but lower down he seems to contradict this truism, thus, "while I only dealt with one point, he has taken a line as his object," and he objects that I have taken one ray from each of two points. Well, my line is a collection of points, so fill in as many rays as may be convenient, or imagine the bounding rays filled in from all points of the line, it will only accentuate the fact that, rays from an object 8in. in length, reflecting an image of 4in. from a plain mirror, where there can be no question of focussing, and then entering a pupil $\frac{1}{8}$ diameter, must be converging rays. Could it be possible for an eye to receive the divergent rays from the sun, it would appear to be of a very different size to that which we now see it; its size would be commensurate with the distance which his rays diverge visibly into space. A distortion mirror gives a good idea of the effect of diverging rays. The convergent cone is all that we can receive; rays diverging from this cannot enter the eye, or only a few of them by artificial means.

I cannot agree with Mr. N. that the eye is the seat of consciousness, it merely receives mechanical effects at present considered as being vibrations of varying wave-lengths, the locale of modification not yet settled. As regards heat as either a painful or pleasurable sensation, it, like light and colour, is a luxury of intelligence; so also with sound—none outside an ear attached to a brain. The stick cannot feel the heat of burning, though its constituents are being driven apart by the violence of the vibration set up in it. The ship cannot know anything of the roaring wind, or the grinding of the rock under its bottom; it is the intelligence on board that hears and sees the danger. So also the coherer knows nothing of Hertz waves; it is simply a mechanical receiver of vibrations set up in the ether by certain material manipulations. Intelligence alone can appreciate them, and the same may be said of all other modes of motion. It is gratifying to find that we agree on two or three points; for the rest we must agree to differ. I hope readers have been edified by the discussion.

Fredc. H. Ewer.

POLISHING AND GRINDING MACHINE FOR GLASS SPECULA.

[43224.]—In response to inquiries, I now send you, as promised, a brief description of the principal details in the construction of the Wassell machine for grinding and polishing specula. The general arrangement of the various parts can be seen by referring to the photograph reproduced on page 383 in your issue of 8th ult., and the two rough sketches inclosed are intended to show how the necessary movements are communicated to the tool and speculum. No attempt has been made to draw these sketches to scale, but the measurements given may be taken as suitable for a machine capable of working discs up to 8in. in diameter. The four upright axles to which the various pulleys are attached pass through the bed and rest in sockets fixed to a bar underneath, which forms a portion of the framework of the machine. They are placed—taking them in the order in which they appear in the sketch—7in., 15in., and 22in. apart. The pulley B is driven by a $\frac{1}{2}$in. belt from A; the others are driven by $\frac{3}{16}$in. cord as follow:—D by C, F (the oval wheel) by E, and H (the speculum table) by G. The diameters in inches of these pulleys are A $1\frac{1}{4}$, B $8\frac{1}{4}$, C $2\frac{1}{4}$, D $8\frac{3}{4}$, E $4\frac{1}{4}$, G $1\frac{1}{4}$, and H 9. The wheel F, which is in the form of an oval, has the V-grooves cut deeply on its edge, the major and minor axes at the bottom of the grooves measuring $8\frac{3}{4}$in. and $1\frac{1}{4}$in. respectively. This wheel is screwed to a circular block which rotates on a spindle fixed to the bed. On the top of this block, the height of which must be determined by the position the tool is to occupy, is fixed a socket, M, in which the rod

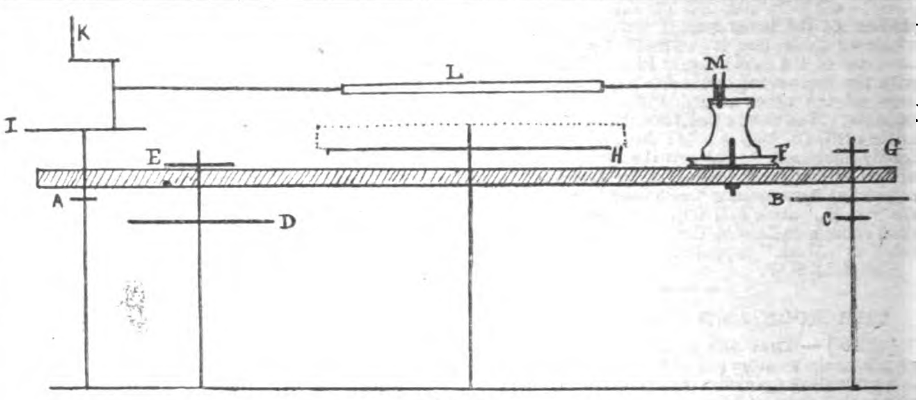


FIG. 1.

supporting the ring L slides backwards and forwards. This socket, which is placed eccentric to the short diameter of the oval wheel, must be free to turn on its axis, and will thus keep the same face constantly towards the operator. The ring L, which communicates the motion to the tool, has four $\frac{1}{2}$in. metal pulleys or rollers attached underneath. The side rollers are placed at right angles to the line of stroke, and the others about $1\frac{1}{2}$in. to the right and left (see Fig. II.) The plates supporting the rollers require to have slots cut for the screws which fix them to the ring, so that the distance between the rollers and tool, and consequently the speed of the latter, may be under control.

Having, we shall assume, made an allowance of about $\frac{1}{16}$in. of "play," the rollers will bear against the tool in the following manner: In the

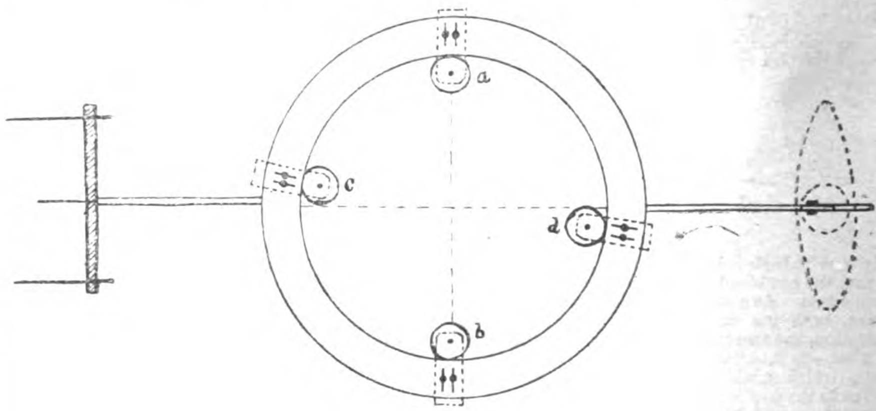

FIG. 2.

forward stroke C pushes tool round against *b*, and in the backward stroke *d* pulls it round against *a*. This motion is beautifully regular, and is perhaps the most ingenious part of the machine. As the ring moves backwards and forwards it is by the action of the oval wheel on the eccentric movement at M (Fig. 1) that the tool is carried from side to side with unequal velocity, whereby the action is prolonged at the centre, and the two extremes passed over more rapidly. The diameter of the circle to be described by M depends on its distance from the polisher and the amount of side motion to be communicated—say, $\frac{3}{4}$in. It will be understood that the extent of this movement of the tool from side to side is in no way affected by the action of the oval wheel itself, which merely regulates the amount of polishing at the centre and sides. The driving handle, K (Fig. 1) is fixed to a circular plate, I, the latter having a $2\frac{1}{2}$in. slot cut where the handle is attached, in order that the length of stroke may be regulated to suit different sizes of discs.

As stated in my former letter, the following figures give the ratio of the various movements:—48 revolutions of driving handle to 1 of speculum, 19 of ditto to 1 of oval wheel, and 240 of ditto to 1 of tool.

Tracings made by one of these machines appeared in your issue of July 23, 1897. These show with what precision and regularity the different curves are produced. If "Speculum" (letter 43133) would oblige by forwarding a tracing by his small Grubb machine, I am sure the Editor will reinsert.

Dalbeattie, Jan. 8, 1900. Alex. Smith.

FIELD ARMOUR.

[43225.]—In reference to my letter (43127, p. 472) and the remarks upon it (43189, 43203 *et seq.*), permit me to say first in regard to my critics "A Fellow of the Royal Astronomical Society," "Sapper," and "A. S. L.," that since I wrote on this subject I have learned that it is actually receiving the practical attention of one of the highest engineering experts in the country, a man who has had more to do with the wholesale manufacture of armour-plates than anyone I know.

I claim no priority of originality, seek no gain, and admit the inherent and obvious defects of field armour. If a shell burst behind a shield, or in front of it either, the shell would blast everything within reach. The same would happen if a shell burst behind entrenchments. Similarly if a sleeper, or even the historic cow, got in front of a locomotive, the engine might be derailed. In many rough places you could not carry the shield. The point is that it could go wherever artillery goes, and beyond. The war expert of the *Daily News*, a soldier, dealing with infantry shields, quoted a few days ago the criticism of Sir Walter Scott on gas-lighting: "Would you believe it?" wrote Sir Walter: "There are actually fools in London who are proposing to light the streets with gas, and other fools who are willing to allow them to do it." Military critics, however, are sometimes too prone to suppose that a humane invention is inspired by mere civilian terror of war. As for the nature of the ground, I assert that at the Modder, at Elands Laagte, and at Colenso, unless the war-artists and photographers are all untrustworthy, there was ample scope for shields. Shields would have taken us to Ladysmith and Kimberley long ago. Whether they should be 5ft. or 2ft. high I do not know. Even 2ft. is enough for cover.

I sympathise with Mr. Bagshaw in his conflict with the War Office. I am pleased that he invented the thing before I did. His wheels, I think, are too big, and would not do for steep ground; otherwise his idea is good. Will he try, as I have been doing, to get somebody to send the shield to the front? Then, War Office or no War Office, there is sure to be a general who will use it.

I like also the notions of "W. B." and Mr. Garniss, and would tender the same advice to them as to getting their inventions adopted. Indeed, I urge this upon them. I have done my part, and am astonished and delighted to find that (as I hinted) at least one expert is actually considering the invention feasible.

Modifying my original plan, I think now that ordinary waggons, or ordinary waggon-wheels with the shield itself as waggon body, might convey the shield to the scene of action. Then it could be erected on its own small iron wheels, the framework of which should extend farther to the rear than in front, in case of steep ground. Or if waggons are not obtainable, the small iron wheels and their frames

could be adapted as in Mr. Bagshaw's drawing, by placing them at the sides.

In conclusion, I would inform "Sapper" that I have not yet communicated with the Commander-in-Chief. It is not impossible, however, that the Commander-in-Chief may have already been made aware of the notion, although I do not know what he would think of it. At all events, neither he nor (I hope) any of the gentlemen who are proposing steel infantry-shields are deserving of such censure as that which is conveyed in the words of Sir Walter Scott which I have quoted; so that we have good ground to hope.

O'Dermid W. Lawler.

FIELD ARMOUR.

[43226.]—I SHOULD like to endorse the opinion of "A. S. L." (letter 43026) as to the employment of field armour in South Africa. Having seen eighteen months' active service in that country, and marched from Cape Colony to Transvaal and back into Natal viâ Zululand, I also know a little of what the country is like, and am sure that the "itinerant" fortifications illustrated in your last issue, and also that of 5th inst., would be utterly impracticable. There are so many objections to the use of these ideas that I am perfectly certain no military man would uphold them.

What our troops apparently require, in order to put them on an equal footing with the Boers, is "extra mobility." If they had to move about, dragging enormously heavy steel shields with them, it certainly would not increase their mobility. I read in an evening paper a short time back of the invention of an armoured mail cart; it was to protect four soldiers, two of whom were to push it, whilst the other two fired from behind it. The inventor entirely overlooked the fact that this arrangement would take away exactly half the effective firing line.

Ex-Soldier.

[43227.]—A LITTLE reflection should convince the advocates of wheeled armour plates that they would be useless encumbrances. In what state, for instance, would the infantrymen arrive at their position? Very much out of breath, and not very fit for accurate shooting; and then what a grand target for a shell it would make, and end up, I am afraid, with being a veritable death-trap. Could not your correspondents arrange for some motive-power other than man to get the target along?—even then, though, it would stick in the mud. Is it not a mistake to have the plate in a vertical plane, and would it not be better to have it lying at an angle with the ground?

The question of armour-plates and shields has no doubt been considered, but an infantry man wants certainly no more to carry. What he really does want is something to carry him. A man after marching a considerable distance is not physically in a fit condition to at once make good shooting, especially after being kept in a trying climate short of food and water. Men cannot fight well on starvation diet; there is no economy in this. We also need to see that men who freely give their lives for their country's welfare are well equipped. A question that may well be asked is, Are the "Tower bolt locks" our soldiers are given to use the best arm our English mechanics could devise? Personally, I think not. And then, again, why was R.M.L. artillery sent to the front? After this perhaps the old guns in the park may be rebored and sent out. Given modern quick-firing artillery, and plenty of it, and shell adapted for the exigencies of the case and filled with high explosives, then perhaps the cheering words of Major-General Hector Macdonald may yet be true, and they will bear repeating—viz., "Let me ask you to remember that whatever you hear, and no matter what people say, our generals are all right, and our soldiers will pull this thing through, and right well, too!"

T. J. Leney.

[43228.]—THE various comments on this subject show a certain amount of ingenuity; but they all seem to overlook the serious questions of weight, portability, and stability. A Mauser bullet will penetrate a plate of wrought iron ⅜in. thick at a range of 350yds.; so if a shield is to be proof at all ranges, it will be required to be made of the best quality of hardened steel of the same thickness. This will weigh about 15lb. per square foot; thus a shield 12ft. long by 6ft. high, protecting, say, ten men, will weigh, including stays and wheels, about 12 cwt. Now what effect would a 37 mm. Maxim, slinging about 3 cwt. of hardened steel shells per minute, each weighing about 1¼lb., have against this? Why, it would be simply so much pasteboard; while a 3in. shell would upset the entire show, and probably save the fatigue party the trouble of digging the long trench. My knowledge of North Natal is confined to a week's stay and two railway journeys; but from what I saw of the country, I should say that shields of this description would be absolutely useless. Many of our readers have doubtless visited North Wales and the rougher parts of the Peak of Darbyshire, and I can assure our readers that these parts are simply meadows compared to North Natal. Just imagine a party of, say, ten men moving half a ton of boiler-plate up Snowden, with instructions to keep off the path! This would be a fair sample of the work which the "armour-plated squad" would have to put up with. "W. B." suggests corrugating the face of the shield to break up the leaden bullets; but surely he overlooks the fact that lead-pointed bullets are barred at present. The Mauser bullet has a lead compound core, covered with a jacket of cupro-nickel (copper 90 per cent, nickel 10 per cent., I think). I do not propose to discuss the mistakes which have arisen, or to suggest remedies; but I do think that our officers at the front know quite as much about the subject as some of the scratch critics who write to the daily papers, and perhaps a little more.

Olytie.

MOTOR CARS.

[43229.]—I AM pleased to see a criticism by one who has had practical experience, though I do not entirely agree with him. Taking the points raised by "Country House" seriatim, I fancy in the first there is a misprint, as I do not know what he means by "the *flat* cords." My intention is to use round cords. As to the actual method of changing the direction of the pull on these cords, a bell-crank lever may be substituted for the pulley; but I prefer to retain the latter, using a short length of chain to take the bending stresses. I know of no better material for taking a strain in tension than good steel flexible cord. The steel must be of the best quality to stand the drawing down into wire; this is in itself a guarantee of quality. I am endeavouring to design the car so that as many parts as possible may be purchased ready made in the form in which they are required for use, as this, I think, will help to keep the cost low. Those who have sufficient mechanical skill to make and fit up levers and links to take the place of the flexible cords will have quite enough sense to enable them to alter the design without elaborate drawings or instructions. As this is expressly an amateur's car, I think that cords will give far better results in their hands than linkage work would do, as the joints in the links, &c., require to be very well made; otherwise backlash and lost motion will be painfully evident, whereas a screw adjustment at one end of the cord takes up all slackness. Next, taking the spring tension to jockey pulley. I have a precedent for this in the Cannstatt-Daimler belt-driven car, which is used at the present time by the Motor Coupé Co., London. I have had a lot of experience with this car, and the English Daimler gear-driven car, and greatly prefer the former. There are four belts and four jockey-pulleys, the belts being 2¼in. wide. The jockeys are applied by spring tension, and I never found any trouble arise from either the width of belts or the springs. The belts used are rather thicker than the majority of single belts, being between ¼in. and 5/16in. thick. If desired, I will forward a sketch of the jockey pulley gear of German Daimler car.

As to the diameter of the sprocket pinion, this, I take it, is a matter of opinion, and gave rise to a long controversy in the Cycling Press some time back. At any rate, so long as the ratio between the driving and driven sprockets is not altered, intending builders can suit their own fancy. The larger the sprockets, the greater the cost for material, cutting teeth, and extra chain. For the chain used in the steering, the belt-driven German Daimler is again a precedent. They used a very small sprocket (seven teeth, I think) and a 3/16in. chain, coupled by two light rods to the axle, which swivelled about its centre in the same way that the front axle of an ordinary carriage does. The strain on the chain was very much greater than in our case where the axle is fitted with pivots at each end on the Ackermann principle, as I described for the quadricycle in "Motor Cycles." In all I did nearly 3,000 miles driving on the belt-driven Daimler, and found no disadvantages on any of the above points. Its greatest faults were the water-cooling device (in fly-wheel rim), which threw the water about with reckless prodigality, the awkward position of starting handle and its cumbersome appearance.

A car has not been built to these drawings; but the design contains the best points of many belt-driven cars, with such improvements as I have found necessary by the best of teaching—i.e., long experience. The whole design throughout is practical. All dimensions deduced from actual practice, it having been my fate to be intimately connected (since before the legalising of the motor-car) with the Daimler, Benz, De Dion, Bollée, Peugeot, and Panhard cars, not only in using them, but in their design, manufacture, and testing.

The Writer of the Articles.

[43230.]—I AM very pleased to see article appearing on "Building a Motor-Car" in your valuable paper, and feel confident we shall learn many valuable hints on same. I would just like to point out to the writer *re* the foot-brake taking off the belts, that I have lately constructed a motor delivery van driven by 2½ belts with loose pulleys. It has three speeds, with separate belt for each, and by simply pressing toe on foot-brake throws the belt on to loose pulley; the same lever works the three belts, and whichever speed the car is travelling, you simply press foot-brake to stop it.

J. W. Riding.

Deeside Carriage Works, West Kirby, Jan. 9.

[43231.]—I AM very pleased to see in your last issue the first of a series of articles on "Motor-Car, and How to Build it," as I am sure there are very many of your readers who are quite capable of building any ordinary car with a little help such as the articles referred to would give, and at a cost probably something like one-fourth or one-fifth the advertised price of a good and useful car by one of the few well-known makers of to-day.

The car designed by the writer of the articles is very much like a "Benz," and perhaps still more like an "Accles-Turrell" car, in outward appearance, and, on paper, looks neat; but, at the same time, to me looks a little crowded, and might be improved by having a little longer wheel base. If the illustration is to scale, I suspect the wheel base to be rather short; but one cannot tell, as no dimensions are yet given, and no scale is attached. Another thing that strikes me is that there seems to be too much weight behind on the driving wheels.

Belts have certainly many drawbacks, but the author is, no doubt, correct in thinking that they are much better than gear for light cars, if of proper size, and judiciously arranged.

As to frame, the author proposes to use wood flitched with steel plates as being more easily worked by an amateur. This is, perhaps, correct; but I cannot think that flitched timber is best for the purpose, although it is used on "Benz" and other cars, and as many amateurs, and, no doubt, very many of your readers are quite as capable of working with steel angle, channel, H bars, or tubes, as with wood, I would suggest that the author gives dimensions of these also; the builder will then be able to use the material of his choice, and that which his experience and practice will best enable him to work.

The idea of using steel wire cords instead of rods is a good one, but I believe not altogether new; but the author seems to make further use of this material than has been done before.

The author claims that there is not at the present time a belt-driven car which can be stopped by putting on the brake only, or rather by a single movement of the brake lever, as in his design. He is wrong, and in proof thereof I would refer him to "La Voiture Darracq," illustrated and described in December issue of *Auto-Motor Journal*. This car has two foot levers: one disengages clutch between motor and car only, and the second lever disengages clutch and applies brake at same time. Also in the Accles-Turrell car, I believe, the action of putting on the brake at the same time slacks the belt, thereby enabling it to slip on the pulley.

Three horse-power seems to me to be too little even for a light car; am certain that most of the cars in use at the present day would be very considerably improved by the addition of from 20 to 40 per cent. more power.

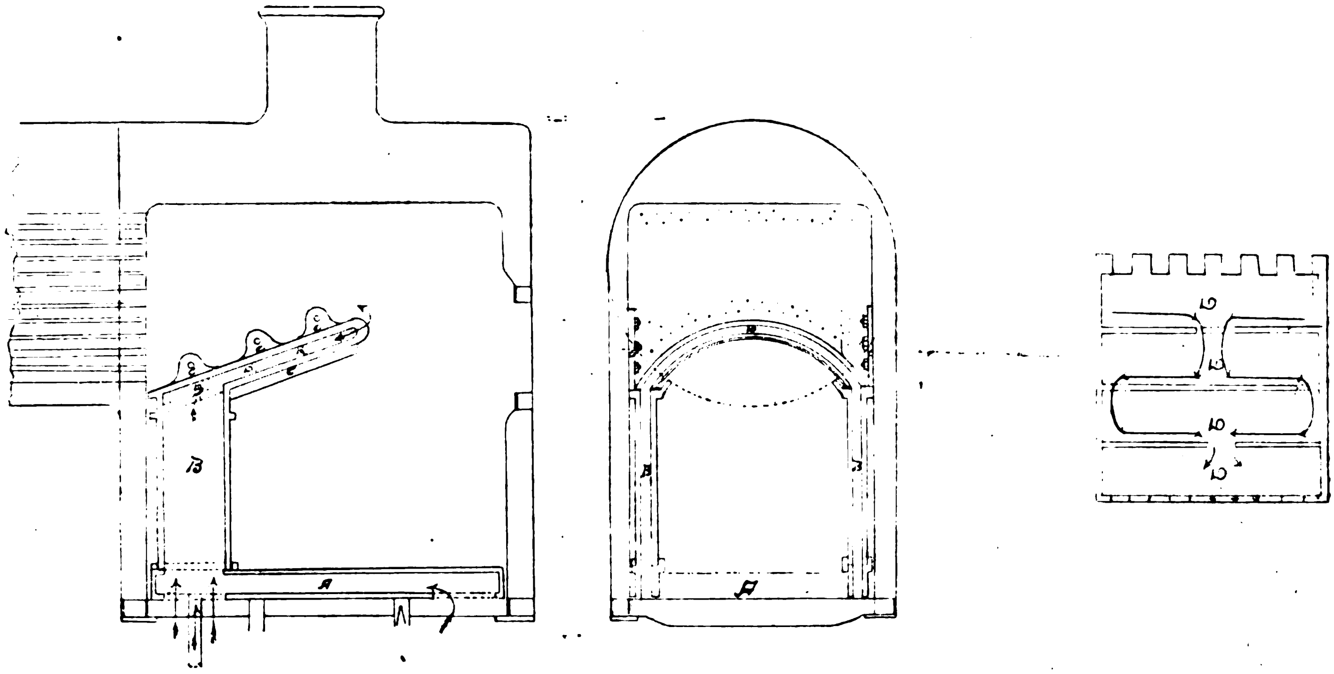
I notice in this week's issue of *Engineer* Mr. New, in an exceedingly interesting article on "Oil-Engines and Motor-Cars," states that the power should be 1¼H.P. per ton per mile per hour for a bad road of a gradient of 1 in 5. Now assuming that under these conditions—which are more common than one would think—we require a minimum car speed of four miles per hour, and that one car will weigh, say, about 9cwt., our power, according to Mr. New, should be 3⅜H.P. The author objects to a large power on his car as a source of vibration; but surely this is a matter of balance of motor, and I quite think that, ere long, motors will be so improved that we shall be able to place an 8H.P. or 10H.P. motor on a comparatively light car, and get therefrom even less vibration than we do from a 3H.P motor at the present time.

In conclusion, I would ask the writer of articles referred to to look upon these remarks as friendly criticism only, and I sincerely hope that you, Sir, will allow the subject of motor-cars and details thereof to be freely discussed, as I am sure that such discussion amongst practical mechanics will lead to vast improvements.

A. Jacks.

ORNAMENTAL TURNING.

[43232.]—MR. EVANS's design in last week's number is a very handsome one, and it would look well if executed in ivory or blackwood, as he recommends. As he very kindly offers to give all information in reference to it, I would be glad to know where one could procure the necessary material of the dimensions he names, as 5½in. is a large size for ivory. Also the probable cost of ivory required to complete the design, and if it could be had cut in the rough to the required dimensions, and *where?* Also the like information as to African blackwood, as to where it can be pro-



cured sufficiently large and sound, and the cost, &c. Referring to his remarks as to step-drills, the draw-back seems to me to be the keeping them in good order. I have a few made by Mr. Evans years ago; but have scarcely used them, preferring to use plain drills, square at the end (like a paring chisel), or round-mouth drill. With an assortment of these of different sizes, step-work can be very cleanly cut, and the necessary sharpening can, of course, be easily accomplished, with or without the goniometer. Of course, the design can be executed on a smaller scale, but I have taken the dimensions given by Mr. Evans; but whatever the size may be, any particulars as to material would be appreciated by **Spherical Rest.**

DETERIORATION OF ALMANACS.

[43233.]—In literature generally, in the size and print of periodicals and the like, there has no doubt been great improvement within the last thirty years. It is singular that one most useful publication—the almanac—has not kept pace with this improvement; at any rate, as far as the astronomical portion of the information goes. Take, for instance, the last year in which a large solar eclipse was visible from this country—viz., 1870. A reference to Francis Moore's almanac for that year will show the times of first and last contact, the greatest phase, the magnitude to the nearest minute of a digit worked out for 30 or 40 different places in Great Britain, also for Paris. A reference to any other year about this period when there was a solar eclipse, as 1867, 1873, 1874, &c., will show the same thing. Why cannot we have an almanac at the present day giving similar information? Some say that this was the work of Mr. Woolhouse, of *Nautical Almanac* fame, and that none will now undertake this most useful information. But, to say the least, the deterioration in almanacs of the present day in this respect seems much to be regretted.

Astronomicus.

AIR ARCH FOR LOCO. BOILER.

[43234.]—In reference to letter 43008, p. 297, Nov. 10, 1899, an "Air Arch for Loco. Boilers," we beg to inclose you a tracing for arch which we applied for and received provisional acceptance. The following are the principal features of our arrangement.

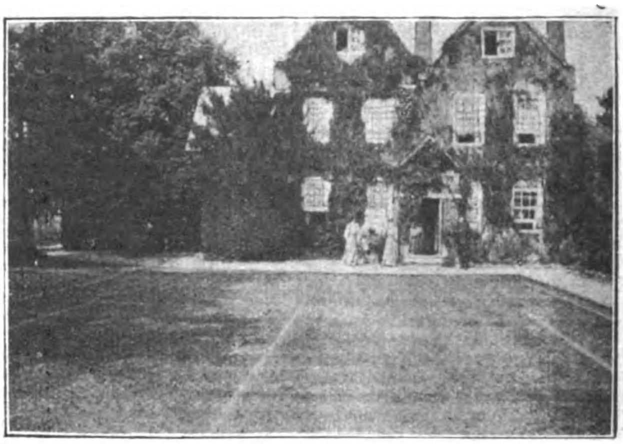
The air is conveyed along a hollow firebar A, open underneath at either end (so that whether the engine is running ahead or tender first the weather end of ashbox will be open) into a flat pipe B placed on to the top of bar A in a socket. The upper end of pipe is attached to a bar, C, the length of the width of the arch D, which is hung to the firebox sides with lugs, the pipe end B coming up through the bar A and forming a spigot. The arch (cast iron) is divided into four parts, D D D, each forming a compartment of its own. The first part, or that nearest the tube-plate, fits into the spigot of upright pipe B, then passes into part D 1, from there into part D 2, going into part D 3, and from there into part D 4, thence through outlet holes into firebox. The air in its passage from the inlet to the exit of arch attains to a great heat, and in coming into contact with the heated carbonaceous gases ignites and obtains a more perfect combustion, and, as a consequence, mitigates the smoke nuisance. To protect the upright pipe B and arch D from burning by closing the ashbox doors suddenly, there is a supplementary pipe E going through the bottom of the ashbox into the upright pipe B, keeping it and the arch D cool, and which in nowise interferes with the fires.

Davison and Reed (Patentees).

Preston, North Shields.

CURIOUS MIRAGE EFFECT.

[43235.]—The accompanying photograph was taken with a pocket Kodak last August. The time was about one o'clock, and the day intensely hot. I venture to think that it may be of interest to your readers from the fact that the central figure in the doorway had no existence. There are three ladies on the left-hand side as you look at the photograph, and myself on the right. The lady



standing nearest to the doorway turned round at the moment when the photograph was taken, so that her back is presented towards the camera, and an examination of the figure in the doorway leads me to think that it is the front view of the lady who has turned round.

With regard to the explanation that it is a double exposure: that cannot have been the case, as all the lines and detail are sharp, which could hardly be the case with two successive photographs taken while holding the camera in the hands. It is true that the middle line of the tennis court appears double; but that, I think, is due to its having been re-marked.

I put the appearance of the fifth figure down to the fact that the sun was shining on the wall, and had made it very hot. The strata of air near the wall would then have been heated to different temperatures, the hottest being next to the wall. The rays of light traversing the strata of air of different densities might then have been refracted sufficiently to come right round and enter the camera lens. The passage and the upright door-post are visible through the figure.

I shall be pleased to hear any other opinions as to the cause of the extra figure. **G. T.**

NOAH'S ANCHORS.

[43236.]—May I invite the attention of your readers to a photograph on p. 117, of the *Strand Magazine* for January of four huge anchors "to be found at Kaironan (*sic*, possibly a misprint for Kairouan, or Kairwan, in Tunis) in North Africa," and said by their guardian to be those of Noah's Ark, and to be of iron, bronze, silver (!), and gold (!!) respectively. They are said to be 15ft. long, and, judging from the figures standing by them, the shank must be about a foot thick. Their rings also, which are apparently adapted for a hemp cable, seem to be about 2ft. 6in. in diameter, and all appear to be in perfect preservation.

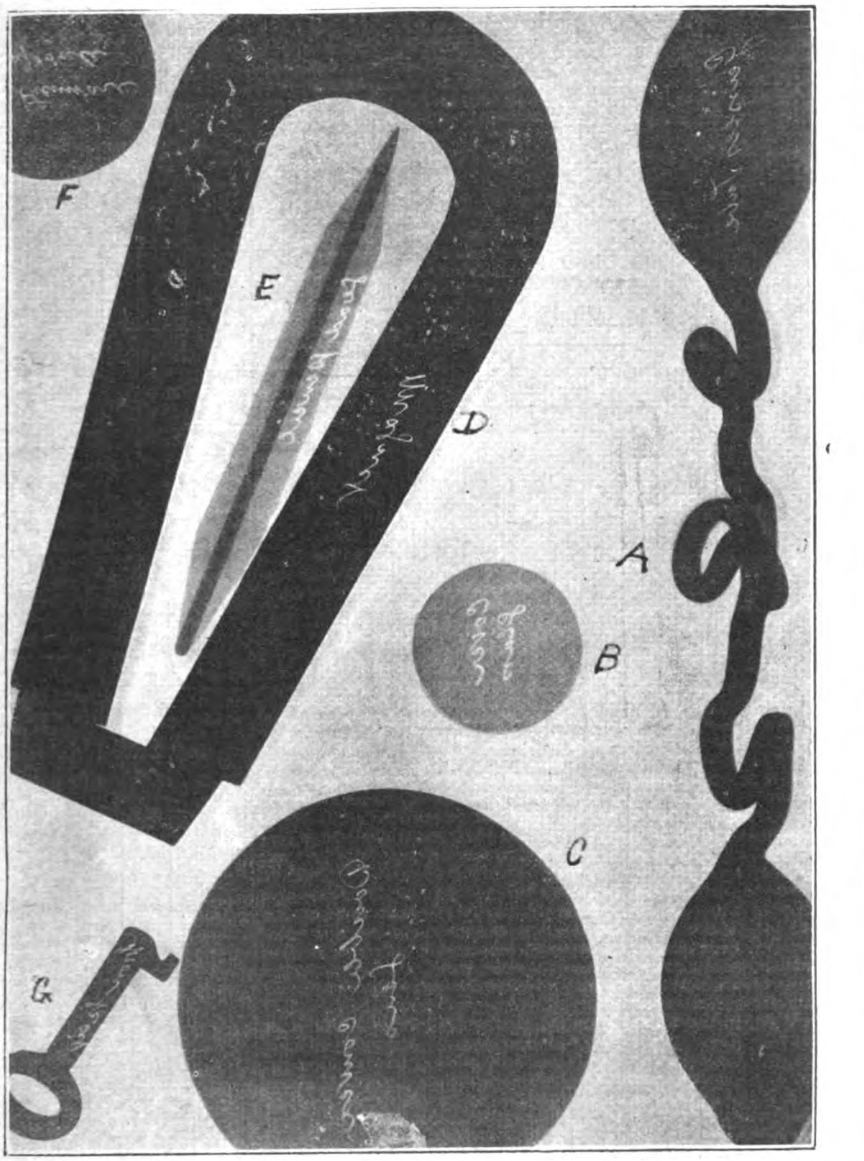
Irrespective of the question of their reputed origin, they would seem well worthy of attention, not only from their great size, much exceeding (if I may trust my memory) that of the *Victory's* anchor, now on the parade at Southsea, which I have always understood to be one of the largest that was made before the advent of the steam-hammer, but from their existence in an inland town—if I am right as to Kairwan. **Faber.**

AIR-SHIP OR AEROPLANE.

[43237.]—I am glad to see F. H. Wenham's letter (43217), for I quite agree with what he suggests—viz., that the next step for solving the problem of flight is to impart some propulsive force to the wings. This I know from my experiments (see *Aëronautical Journal*, Vol. I. part 4, Oct., 1897) is feasible by flapping the wings, and might be done for a short time by a muscular man in a specially-constructed machine. The machine would only travel slowly, when there should be no difficulty in obtaining equilibrium by lowering the centre of gravity as much as found necessary. I refrain from details, as their description would take up much space. **R. F. Moore.**

AN X-RAY CURIOSITY.

[43238.]—I send with this a radiograph of miscellaneous articles taken by myself recently; about



one item on which, if you find it possible to reproduce the same, I should much like a little information from some practical physicist. I refer to the Geissler tube marked A. The greater part of this article is made of—so far as the eye can judge—ordinary white glass; and the central twist, in juxtaposition with the A, is stained a bright pea-green. This central part appears to the eye every bit as stout in material as are the twisted portions of the white glass at either end of it. Now, can anyone tell me why the said pea-green glass is more transparent to the X-rays than any part of the white glass is? Even where the twist upon itself makes the thickness double that of the white, it is clearly less opaque. I presume the metallic colouring is responsible for the difference, but how?

The other articles shown are: B, a micro-cover glass; C, a double-convex lens; D, a magnet; E, a short length of blacklead pencil; F, an earthenware capsule; G, an iron key.

William Godden.

IS THE THEORY OF GRAVITATION A FINALITY?

[43239.]—LIKE Mr. Alexander (p. 452) I also do not consider the usual explanation of planetary motion to go far enough, and nearly 20 years ago enunciated a theory on solar emanation, which, I think, contains a probable answer to some of the questions he has a wish to inquire into. The theory was based on the antagonism of motion to attraction, and my reasoning and remarks were somewhat as follows:—

The law of gravitation gave the key to what had been previously inexplicable in planetary motion. It showed us how mass was attracted by mass, and how world was influenced by world; but it seems to have altogether overlooked the force which must result from universal attraction opposed to universal motion. Is it here we are to seek for the force that builds up a sunbeam?

If we rub a glass rod with a piece of silk it becomes warm through friction; but, independent of this, its attractive properties are greatly increased, and is found to emit light and heat when brought into contact with the earth. What has brought about this change? The answer is, Motion. But motion alone would never have had these effects unless there had been a prior mutual attraction between the two bodies. This imperceptible attraction was overcome by the motion, and the result was that the attraction was not only increased, but the surplus force appeared in a spark, as light and heat. If, under peculiar circumstances one magnet is revolved in front of another magnet, the same effects are observed, although in this case there is no contact between the two bodies. If we disturb the attraction which holds together the atoms of a chemical compound, whether it be in the solid, the liquid, or the gaseous state, we have this same emanation of light and heat. If, then, such effects can be produced in our laboratories, infinitely greater effects must result in the Solar System, as we have there the initial conditions of above experiments in the struggle which is continually going on between attraction and centrifugal force.

Taking the Solar System in its simplest form, it consists of a central body turning on its axis, the sun, round which at various distances is circling other rotating bodies, the planets. All these bodies are on practically the same plane, and are held together by attraction; but owing to their continual motion, the attraction is being continually broken. Now, it must occur to everyone who has had the slightest acquaintance with electric construction, that we have here all the elements of a huge electric machine, call it statical induction, or dynamo electric, it matters not; but for simplicity let us see in it a type of the modern dynamo, with the planets as so many field-magnets, and the sun as an armature flashing forth its surplus charge to its attendant planets. But we must have some proof that it really is what its arrangement would indicate, and we, fortunately, have such proof in the appearance that a comet is found to present in its approach to and recession from the sun.

According to the more advanced theories regarding comets, they are thought to consist of solid matter, and rigorously to conform to the laws of gravitation, and strictly to follow out their orbits. When a comet is far away from the sun, it appears very much like ordinary stellar matter; but as it gradually approaches the sun, and as its motion increases, it becomes more brightly illuminated, and sends out short streaks of light sunwards. Shortly these streaks are forcibly driven back, as by some repellent force, and gather about the head of the comet in a bright halo. On a nearer approach this halo appears to be partly thrown off, and one or more tails formed on the side away from the sun. When the comet sweeps round the sun its tail wheels round along with it, always keeping away from the sun, and as it recedes its tail—which is now in front—gradually dwindles away, until it appears as ordinary stellar matter again.

As comets (at least those that we have most to do with at present) travel in infinitely long ellipses, and strike the plane of the Ecliptic at a considerable angle, they may be considered, for all practical purposes, not to participate in the general circular movement of the planetary system; and when crossing the plane of the Ecliptic they will therefore be nearly stationary, and under the same influences as the sun himself. Let us see if a cold dark body, thus thrown within the influence of the contending forces takes on the appearance of a sun, that is sends its surplus force planetwards.

When a comet first makes its appearance we see it through our telescopes as a faint, hazy, undefined body, which appearance very probably results from a deficiency of power in our instruments. As it approaches the sun, short streaks of light spring forth sunwards, or rather an electric discharge passes from it towards the sun, owing to its having been formerly the rubber, and consequently endowed with a different kind of electricity. As it gets further within the influence that (according to these speculations) forms a sun, a repulsive action takes place between it and the sun (see double stars) owing to their now being charged with the same kind of electricity; in fact, for the time being it becomes a sun, and emits light in the direction of the rubber, or outer planetary matter, in the same manner as the sun himself.

But our hypothetical machine wants regulating, and to attain a good, self-regulating dynamo, we must assume that gravitation itself—i.e., universal attraction—is but the product of the action of motion upon mass, in the same manner as we assumed that the manifestation of physical force is but the outcome of the action of motion upon attraction. If we do this, it is at once evident we are dealing with balancing powers, and that any acceleration of planetary motion must result in increased attraction, which attraction would, of course, retard motion, and restore things to their normal condition.

In the foregoing speculations we have been working with natural powers, and assumed nothing but what is capable of proof or denial, some way or another. But when we attempt to formulate a working hypothesis on the creation of such structures, we have at the very outset to enter upon assumptions beyond the remotest chance of experimental or even intellectual inquiry. We have, as a matter of fact, to assume a Creator giving the initial push to primordial matter; and we have to see in primordial matter a trace, however small, imparted or inherent, of its usual attractive properties, for, unlike mass, it is inconceivable that matter itself (that is, non-attractive matter) could in any way be acted upon by motion however energetic. With these assumptions as a start, and our speculations to carry us through, a possible theory can be built up somewhat as follows:—

In the beginning "the earth was without form and void," or, in other words, there was matter, but no motion. To this inert matter motion was given, when it immediately became as it were a thing of life; atom whirled around atom, and as the outcome of the action of motion upon such matter is attraction, atom clung to atom, and molecule rushed towards molecule, to form the nuclei of future worlds. Everywhere these nuclei went spinning round, forming vast whirlpools (see Spiral Nebula in Canes Venatici) in their efforts to gather up as much matter as their fellows; but, owing to difference of speed and proximity of material, all were not alike successful. Among the less successful were some tiny masses furiously whirling away in their vain endeavours to overtake their more bulky companions, who had already swept up everything within their reach, and were now striving to draw their little friends within their grasp, but, owing to these smaller masses being endowed with a rotary motion round their own axis, the only effect which the attraction of the larger masses had on them was to convert part of their rotary motion into centrifugal force, which conversion had not only the effect of balancing the attraction, but also of swinging the satellites into the same plane as their primaries.

While this was going on among the comparatively smaller bodies, in our own system there was one huge mass (the sun) which had already sucked all the surrounding matter within its mighty vortex, and was now seeking to bring these rival systems within its powerful influence; but as satellite was rolling round planet, and planet was spinning round on its axis, it had no longer to deal with the infinitely small particles of which it had just been

built up, but with masses composed of the same material, and endowed with the same motion as the sun himself. He tried to draw them in: but as his attraction diminished with distance, and as the bodies on which he was exerting his attractive power possessed considerable magnitude, the attraction was greater on the near than on the further side of each individual planet; the effect of this, combined with their rotation, being to cause them to fly off at right angles to the attracting power, but still held by the attractive influence they were swung to the same plane, and rolled round the sun as a centre.

If the whole had ended here, and the planets been destitute of the power to increase or diminish the sun's attraction, the retarding influence of such attraction would have gradually overcome centrifugal force, and the planets would have been gently swept on to his surface, the whole matter of the universe thus ultimately coalescing into one monster mass, which, being no longer acted on by external matter, would have eventually returned to that void from which it sprang. But such was not the case; each planet, as it was added to our system, increased the sun's attraction, enabling him to stretch his influence still further out, and bring within his sway the more distant worlds. Attraction was increased, but so was motion; the fight between attraction and centrifugal force began, the core of our huge dynamo-machine became covered with a brilliant shroud, and the sun shone out in all his splendour, radiating his light in every direction, as it were in payment of the force expended to maintain him in his glory.

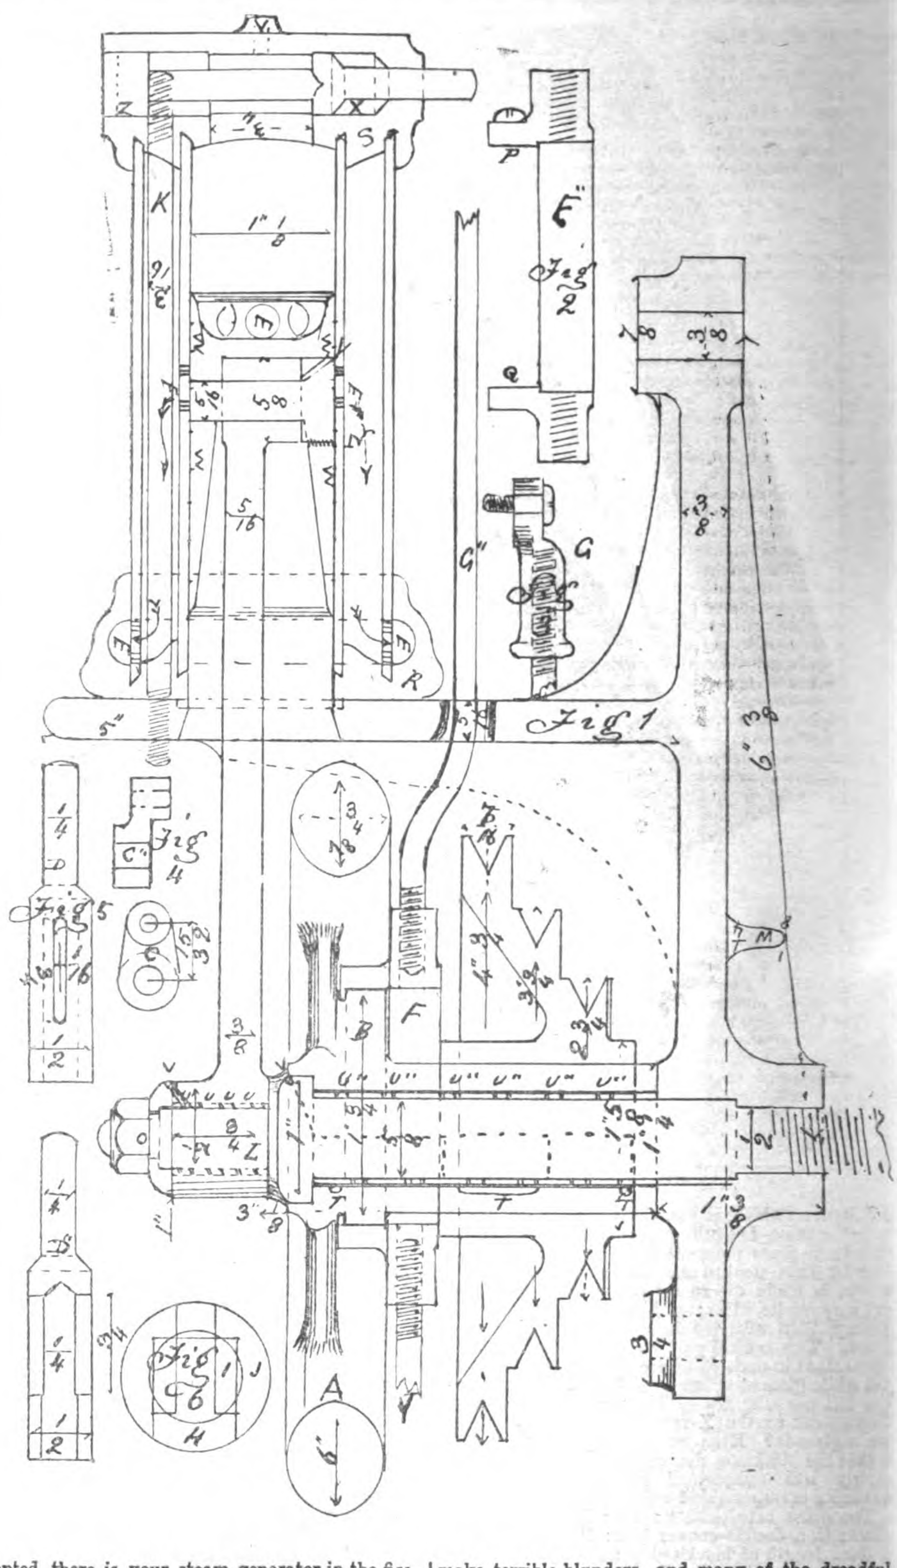
Along with these formations and arrangements of new worlds, there were at the same time small bodies (comets), which at the balancing of the more important masses, were situated midway between two contending powers, one of which for a time got them within its influence. Their speed, at first slow, gradually went on increasing as they got nearer to the attracting body; and as they were almost destitute of centrifugal force, owing to their having two centres of revolution, they appeared to be driving right on to the surface of the sun. Faster and faster they rushed along, until it almost seemed as if these puny masses were destined to overturn the equipoise of our system. But a sudden change took place; the comets had reached the region of contending forces, attraction was immediately changed into repulsion, and they swept round their huge relation uninjured by his power. Out into space they went, throwing off their bright trappings as they neared their starting-points, there to set out on a new pilgrimage, through other systems and round other suns;—their chief use in celestial mechanism being to hold system unchangeably separate from system, so that the motion of the one shall not in any way interfere with the correct working of the other.

And thus, in unchanging constancy, all shall remain, each unit fulfilling the part it was destined to play, satellite rolling round planet, and planet round sun without reduction of speed or diminution of force, until this great strucsure has accomplished the object for which it was created, when it will return to the void form whence it came. Not, however, by the clashing of worlds or the cooling down of our resplendent orb, but by the command of Him who gave it birth, that all be still, when the whole fabric will immediately return to its inert pristine condition without even the power to fall asunder.

R. L.

HOW TO BUILD A LIGHT ENGINE FOR VARIOUS PURPOSES.—IV.

[43240.]—ABOUT the early "fifties" I paid a visit to an engineer's shop, and was put out a bit as to the arrangement of machinery—i.e., tools and some engines—and was rather mystified; but upon arriving at the shop end and looking round again, I became somewhat enlightened. There, on the ground, were a couple of stout cast-iron I-girders let into the wall across the angle of the shop. These were no more nor less than parallel pieces. Upon these was a very large cylinder undergoing the process of boring out; above that was the motor part of the mill mounted upon a couple more girders, and below was a good deep pit. I had no idea that so large work was done in so small a shop. This, of course, accounted for what I see—i.e., machines bracketed to the walls—and therefore all was clear below for getting the cylinders and other large castings in position to work on. I thought then what an excellent arrangement it was: engine for boring cylinders, or kept going until they got through. Well, fancy a nice little engine bracketed to the wall for such a purpose, up out of harm's way, and ready to do duty any time; very little or any attention. What could be better! Now, when you have a small engine, the question is, What will you do with it? Where will you put it? If I might suggest a place, I should say: Build it with an entablature, and caulk it into the chimney-breast over the mantelpiece—i.e., make wallflowers of them. Other things could be served the same, or they could be mounted upon an inch floor-board, and put up against the wall, only, if the first plan is



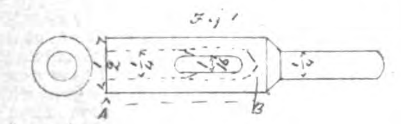
adopted, there is your steam generator in the fireplace, your water-tank upon the mantel-shelf, and, directly under, your engine with the feed-pump in it, and driven by the same motor that drives your valve. The following sketch is an engine for such a place. I have only shown it there with a 6in. flywheel; that you can augment by making the connecting-rod longer, and having a greater distance from the under-side of the bracket of the entablature, will be longer in proportion. I could have given a longer sketch, only I am restricted as regards paper and board on one side, and space upon the other, and it is easy enough to make any additional length if required; and I should advise anyone who goes in for these to make provision for more power if required, which can be easily done by making the bed an inch wider, and distance from under-side to stud for wheel longer. A larger cylinder could be built and put upon bed, and valve arrangement and other things remain the same; and the discarded cylinder, I have a notion, will fetch its price, so you will see how economically you can augment your power. You smile, I daresay, some of you, and say: "H'm, that sounds all right." Yes; and it is there I have stated a few blunders that have come under my notice. I merely do this to show you that so-called engineers make terrible blunders, and many of the dreadful so-called accidents, if you could trace them (and it is easy to trace them when you know your way about), are more generally gross neglect, and we will say nothing about the blunders that I know of. Now for the sketch. Dimensions are given as it stands. Fig. 1 is, taking it all round, an elevated section; Fig. 2 is the gate that carries the rubbing pieces for conveying the motion of the eccentric to the valve-gear, this acting very similar to an elliptic chuck for a lathe. Fig. 3 is the joint end that continues G" to work the bell crank. Fig. 4, C", being section, and C' face of same. Fig. 5 is the outside of valve, and the one underneath is transverse section of same; steam is taken up the centre, and then through the port. Fig. 6 is cross section of piston through pin and joint of connecting-rod. A is the flywheel; B the eccentric; C" and C ball-crank for valve-gear; D' D" steam-valve; E E exhaust holes into jacket; F gate for eccentric; G" C" valve-rod and connections for bell-crank; H, Fig. 6, pin; I joint of connecting-rod; J trunk piston; K one of the long $\frac{3}{16}$in. bolts, *not large ones*; P and Q where the rubbing pieces are to be put; F the frame or gate, cast all in one piece; L big end of connecting-rod on the pin. *Re* crank-pin, you will see a tube full of holes

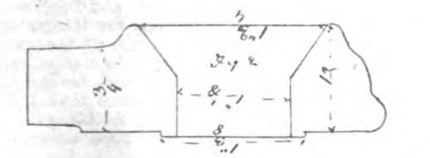
staggered all over it, *u u u u*; the same upon the main stud *u u u u u u*, and this is full of holes; T T T recesses for oil; V a place for a milled-headed screw, that is for the introduction of the lubricant; X and Z packing rings; S the steam-chest and cap, and R the base ring carrying the belt for the exhaust and tube for outlet, E E E E, showing the passage of the exhaust S R. Figs. 2, 3, 4, 5, and 6 may be made of any of the bronzes; the rod for driving of malleable iron, wrought iron, or mild steel; the loose bushes of solid drawn steel tube; pins of steel. N is a piece of brass wire screwed between the joint of pin and piston to keep it in its place; entablature of cast iron will do.

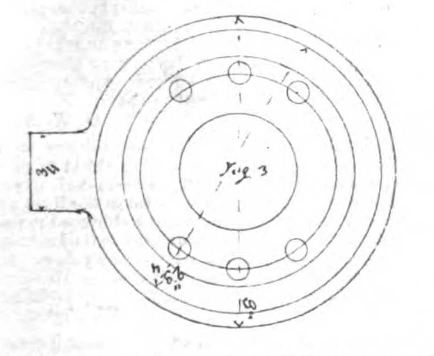
Jack of All Trades.

HOW TO BUILD LIGHT ENGINES.

[43241.]—IN answer to "Bonchurch" (43175), no. I am aware that the sketches (Figs. 2 and 3) are not mentioned in the text, because I had an idea that they would explain themselves without any great stretch of imagination. If you refer to the sketches mentioned you will see cylinder-end (Fig. 1) directly under it, which is the same only another view, or rather two views of the same, giving an idea for the pattern-making, which is simple enough. You ask where the brass triblet tube comes in, and for what purpose. Have you







read the text, and referred to F F F F, where the holes are in the steel tube for the exhaust? It exhausts through these holes into and between both tubes, makes its way down to F F, on through the triblet-tube into a belt at D, and makes its exit at the right-hand side at or just above D. This can, of course, be put in any situation to accommodate other affairs—i.e., it is not bound to be in that position; but it must be shown, as, if there is no opening for the exhaust, *it will not go.* I mention this because you may be warned; but you will not be the first who has sealed things up and expected them to act. And dimensions are given which must be looked after—for instance, a connecting-rod too long or the throw of the crank longer than your cylinder. I was called in to see an engine once that about forty men had been eight months trying to start. I stated what was the matter with it, and the next time I was that way I found a 1½in. lead collar put between the top cylinder cover and cylinder, and I have been told recently that the engine is still working like that. That was over 40 years ago. This plant was laid down by a well-known firm of engineers in London. In article 2, Jan. 5, 1900, I see I have given the port for the admission of steam as $\frac{3}{32}$. That was guesswork, and is wrong. The proper dimensions are given with diagram above, upon the same page, where it is shown how to get the position of eccentric. If this is not toothed, too, you cannot expect to get other things to act, as it will not take steam or cut off properly at the desired spot for expansion. With this I have forwarded the bottom of No. 1, on p. 428, Dec. 22, 1899. This shows you how to make the pattern, and gives dimensions, and it can be bored, turned, and fitted to the tubes as shown. Fig. 1 is the valve; the hole may be extended up as far as A B, which will make it much easier to get out the port, which might be cut out with a small circular saw. Fig. 2 is showing you a section of the pattern for the bottom D, and Fig. 3 dimension for moulding out side and position of holes. But do not mark them off or drill for them until you have decided where you want to turn your exhaust. The section to work to being given before in the cylinder elevation. There are only two holes shown in the triblet tube into the belt in D. Make as many or more as there are in the steel tube. The exhaust will keep the cylinder well drained, and it will be steam-jacketed by the exhaust.

Jack of All Trades.

TWENTIETH CENTURY.

[43242.]—MAY I take your valuable space to reply? Whether Anno Domini dates from the birth of Christ or from the time He was one year old can make no difference now, except that it would strike one that all dates of 1900 would be conveniently placed in the century. I think it is admitted that all other creatures except Christ had a first year, and that when they were any number of years old those years would have passed, so also in the exceptional cases of 100 years their century would be complete. I think a note should be made that the Emperor William's opinion, that the century was complete in 1900, is only the general consensus of scientific opinion in Germany.

W. F. Stanley.

AN OLD CRIMINAL TRIAL.

[43243.]—IN looking over reports of some old criminal trials, I met with one which may interest your readers. The date is 1787. In that year John Elliot was tried for firing at Miss Mary Boydell with intent to kill. The shot (or shots) was fired so close as to set her dress on fire, and there were two contusions on her body, said to correspond with the two pistol-barrels. But why was she not seriously hurt, or why did not the bullets enter her body? A surgeon who was examined, but whose name is not given, supplied the following explanation:—"It was certain that a pistol put quite close home to any resisting body, and discharged so as not to have the assistance of the air, lost much of its force."

The unintelligent jury, however, interrupted the Recorder in his charge by stating that it was clear to them that the pistol was not loaded with ball. But this was not the defence. It was insanity; and a Dr. Symonds was called to prove this. He had formed this opinion from a letter written to him by the prisoner in the preceding January, "the purport of which was a philosophical hypothesis that the sun was not specifically a ball of fire, but that his heat proceeded from the quality of the atmosphere that surrounded his body." The *Annual Register* adds: "Some part of this paper was read, and, so far from betraying symptoms of insanity, it had all the marks of quick and cultured parts. The hypothesis, however false, was ably argued."

Was John Elliot the first to maintain that the light and heat of the sun came from what is now known as the Photosphere? The jury acquitted him.

W. H. S. Monck.

USEFUL AND SCIENTIFIC NOTES.

THE stain of banana juice is almost indelible. It does not proceed from the stalk or plant, but exists in the green fruit as well, from which, when cut or bruised, it exudes in the shape of viscid milk or cream-like drops.

A NEW roller-boat is being built in Canada. This vessel is a cigar-shaped craft about 30ft. in length. The screw consists of a cylinder about one-half the length of the boat, situated in the centre and passing entirely around the hull proper. This cylinder is supplied with fins or wings running diagonally around from one end to the other, and their rotation gives motion to the hull. The keel, connected at both ends to the hull proper, hangs below the revolving cylinder.

THE largest single owner of blast furnaces in the world is said to be the Austrian Alpine Montan Gesellschaft, which owns 32 furnaces. These are mostly of small size, however, and run on charcoal iron. William Baird and Co., Glasgow, own 29 furnaces, including the works at Gartsherrie, Eglington, Lugar, and Muirkirk, Scotland. In the United States the Carnegie Steel Company owns 17 furnaces, the total annual capacity of which is 2,200,000 tons. The National Steel Company owns 12 furnaces, the total annual capacity of which is about 1,205,000 tons.

AN Admiralty order has been received at Pembroke Dockyard directing that the armoured cruiser *Drake* must be hurried on so as to be launched, if possible, in October next. The *Drake* was laid down on April 24 last. In the ordinary course her launch would not have taken place until the summer of 1901. She is 500ft. long, and will have a displacement of 14,100 tons. The engines will be of 23,000 H.P., and the maximum speed with natural draught 23 knots. These cruisers, when completed, will be the most powerful of their class in the world.

REPLIES TO QUERIES.

*** In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[96878.]—**Trigonometrical (U.Q.)**—Suppose the angles B P C, C P A, A P B are called u, v, w, and the side of the triangle is called x, then, of course—

$$\cos. u = \frac{b^2 + c^2 - x^2}{2bc} = l, \text{ say}$$

$$\cos. v = \frac{c^2 + a^2 - x^2}{2ca} = m$$

$$\cos. w = \frac{a^2 + b^2 - x^2}{2ab} = n$$

and since $u + v + w$ is zero, or four right angles, there is a relation between the cosines, namely—

$$l^2 + m^2 + n^2 - 2lmn - 1 = 0,$$

which leads to—

$$x^2 [x^4 - (a^2 + b^2 + c^2)\, x^2 + a^4 + b^4 + c^4 - b^2 c^2 - c^2 a^2 - a^3 b^2] = 0.$$

The required solutions are x_1 and x_2 where x_1^2 and x_2^2 are the roots of the equation—

$$z^2 - z(a^2 + b^2 + c^2) + a^4 + b^4 + c^4 - b^2 c^2 - c^2 a^2 - a^2 b^2 = 0.$$

And, consequently—

$$x_1^2 + x_2^2 = a^2 + b^2 + c^2$$

$$2 x_1^2 x_2^2 = (b^2 - c^2)^2 + (c^2 - a^2)^2 + (a^2 - b^2)^2.$$

I do not at present understand the point of the apparent solution $x^2 = 0$. The greater root corresponds to the case of P inside the triangle, and the lesser root to that of P outside.

QUIVIS.

[96919.]—**Floating Body in the Air (U.Q.)**—Mr. Maskelyne wisely keeps his secrets well guarded, so most of us can only state our opinions. It is certain that without actual contact no arrangement of magnets or other electric apparatus can keep a body suspended at rest in a fluid (like air) less dense than the body itself, and likewise at rest. Such a state of equilibrium, though conceivable, is unstable, as can be shown mathematically. As far as I can see, the only alternatives are either (1) the human body is held up by wires or other supports—i.e., it is not "floating"—or (2) it is buoyed up by gas, balloon fashion. The amount of space required for the second idea puts it out of court altogether, and I vote for wires, in spite of all the stick-waving.

QUIVIS.

[96969.]—**Oscillations of Pendulum (U.Q.)**—The times of oscillation of the pendulums are as the square roots of their lengths. Hence, the number of oscillations made by each per second is as the inverse square root of its length. It follows that the numbers of oscillations the two make in a second are respectively—

$$\left(\frac{l + c}{e}\right)^{-\frac{1}{2}} \text{ and } \left(\frac{l - c}{e}\right)^{-\frac{1}{2}}$$

i.e.,
$$\left(1 + \frac{c}{l}\right)^{-\frac{1}{2}} \text{ and } \left(1 - \frac{c}{l}\right)^{-\frac{1}{2}}$$

i.e., expanding by binomial theorem—

$$1 - \tfrac{1}{2}\frac{c}{l} + \frac{1\cdot 3}{2\cdot 4}\frac{c^2}{e^2} - \ldots.$$

$$\text{and } \quad 1 + \tfrac{1}{2}\frac{c}{l} + \frac{1\cdot 3}{2\cdot 4}\frac{c^2}{l^2} + \ldots.$$

The sum of these numbers is approximately—

$$2\left(1 + \tfrac{3}{8}\frac{c^2}{l^2}\right)$$

Hence, the combined number of oscillations made in a day is—

$$24 \times 60 \times 60 \times 2\left(1 + \tfrac{3}{8}\frac{c^2}{l^2}\right).$$

QUIVIS.

[96987.]—**Series (U.Q.)**—The given series may be written—

$$J = 1 + x + \frac{x^2}{2!\,2!} + \frac{x^3}{3!\,3!} + \ldots.$$

whence we get at once—

$$\frac{dJ}{dx} = 1 + \frac{x}{2!\,1!} + \frac{x^2}{3!\,2!} + \ldots.$$

and—
$$\frac{d}{dx}\, x\, \frac{dJ}{dx} = 1 + \frac{x}{1!\,1!} + \frac{x^2}{2!\,2!} + \ldots.$$

or—
$$\frac{d}{dx}\, x\, \frac{dJ}{dx} = J.$$

Change x into $-\frac{u^2}{4}$

and the equation becomes—

$$\frac{d^2 J}{du^2} + \frac{1}{u}\frac{dJ}{du} + u = o$$

which is known as Bessel's equation of zero order. Hence the given function must be of the form $A J_o(u) + B y_o(u)$, where J_o and y_o are the standard

solutions of this well-known equation. It happens in this case that A is unity and B zero, so that the given function is—

$$J_o [2(-x)^{\frac{1}{2}}]$$

It is impossible to express this in finite series form in terms of any of the simpler functions, such as log. x or e^x, but it is clear that it is the same as the constant term in the expansion of $e^x\left(t + \frac{1}{t}\right)$, where t is regarded as the variable. I fear none of us can do more summing for you than this.

QUIVIS.

[97162.]—**Dynamo as Motor (U.Q.)**—The reason your 300-volt dynamo will not give any power as a motor on a 100-volt circuit, is because it is not supplied by sufficient pressure at terminals. The resistance of the field coils is, of course, too high to allow sufficient current to pass to magnetise the field-magnets. Put your F.M. coils in parallel, and then see what power it will give.

Dudley. WEBSTER MICHELSON AND CO.

[97174.]—**Water Power.**—I am much obliged to "Metope" for noticing my question regarding power to be obtained from 6in. water supply pipe, and would be glad to know where the tables could be obtained. The 6in. pipe is about 14in. under the level of a practically inexhaustible supply, and can deliver the water to a tail race 4½ft. below the top level of the aforesaid supply, so I conclude the pipe ought to be filled, unless friction of water reduces the quantity, the length of pipe from supply being 40 yards.

J. S. S.

[97180.]—**Marine Navigation.**—No, "G.S.N.," the statement is not "rot," but the actual truth. The feat of getting something out of nothing has nothing to do with the question. In a big liner the exhaust steam from the numerous auxiliaries amounts to a large quantity, and it is led, as a rule, into the low-pressure cylinder receiver. After the engines have been started and a good vacuum established, this auxiliary engine exhaust steam is sufficient, in conjunction with the vacuum, to keep the big engines turning, and so drive the ship slowly. In the Navy this exhaust steam is now used for evaporating fresh water for the boilers, and answers very well.

J. H. H.

[97191.—**Disinfectant.**—Nitrate of lead is a well-known disinfectant, and has been mentioned in back volumes years ago. I think it is recommended by the medical officers of health to hang up a sheet soaked in a solution of nitrate of lead in front of the doorway of a sick-room in which there is an infectious case. The "disinfectant" mentioned by "Rotos" may be something special, as common salt is to be added to the water used as solvent; but if chlorine is given off by the reaction, I should prefer to be in the vicinity of the "infectant" rather than in that of the disinfectant.

S. R.

[97193.]—**Lantern Slides.**—Some of the best articles on lantern slides that ever appeared were published in the ENGLISH MECHANIC about 1871 or thereabouts; but, naturally, the numbers are out of print. I think Mr. Hughes, of Kingsland, published them in separate form. As to the special subject of the query, aniline colours can be used anywhere, provided they are mixed in suitable media. Some of them will not stand light for long. There is abundance of information on the subject in back volumes, and nowadays there are manuals which help the amateur which did not exist when this paper supplied so much useful information.

ESSAR.

[97221.]—**Telectroscope.**—I know nothing about this apparatus—therefore am I competent to answer the query. That is, I have hunted up every likely source of information, and can't find anything definite. All that has appeared seems to be mere newspaper "twaddle," which, however, should be published, because it sets "brains" thinking. To those who know something of "fundamentals" it is amusing to read newspaper reports. When we "see by wire," where will the wire be—in the eye or outside? There is nothing impossible; but will anyone be able to see round a corner—or more important, perhaps, be able to shoot round a corner?

T. P.

[97225.]—**Acetylene Burners.**—If the querist cannot make suitable burners for his lantern from the many descriptive articles given in your pages, he should consult those who advertise, and tell them exactly what he wants to do. His query is about as vague as possible—especially as to the "relative positions."

T. L.

[97230.]—**The Blue Eye.**—I suppose that Tyndall was referring to what Helmholtz had said in his lectures, collected under the title of "Recent Progress of the Theory of Vision," translated by Dr. Pye-Smith, and published by Longmans in "Popular Lectures on Scientific Subjects," 1873. As to a "blue eye" being simply a "turbid medium," that may be true enough; but it is also true of any colour eye—if true at all. See Helmholtz on "Light." He was "called over the coals" for saying that the human eye was not exactly a perfect optical instrument; but it did not matter—he was master of the coals.

S. R.

[97232.]—**Maxim Guns.**—The query should be put to the source of publication. All sorts of statements about guns are made nowadays; but where is the authority?

M. L.

[97263.]—**Organ Building.**—I notice in this query that there is to be a stop of 56 pipes called Piccolo of 2ft. pitch. What size will be the pipes of the upper octave, &c. Surely there must be some mistake about "56 pipes" of 2ft. pitch. I have seen some small pipes, but not a full row of 2ft. I suppose that what is meant is a half-row of Piccolo 2ft. pitch, but I should like to know whether a complete set of Piccolo (2ft. pitch) has been made.

W. A. J.

[97283.]—**Motor Tricycle.**—Let the shaft be a light driving fit, with two keys at 90° to each other, also well fitted, and there will be little trouble. Has "Jack" ever tried to assemble the shaft he describes, when both pins fit tightly? Finally, the method indicated by the writer of the articles is by far the best for the purpose, and "Monty's" method of machining quite reliable; but the disc should be properly lined out before chucking.

TURNER.

[97284.]—**Geometrical Progression.**—Concerning Mr. Burgess's remarks on p. 498, top of column 3, the introduction to my solution on p. 189 does not involve the use of any formulæ which would be unfamiliar to a beginner. The phrase, "it is easily shown, &c.," is a common form of abbreviation by omitting easy steps. I gave "Ontario" credit for seeing that

$$\frac{S^2}{\Sigma} = \frac{\dfrac{a^2(r^n - 1)^2}{(r-1)^2}}{\dfrac{a^2(r^{2n} - 1)}{r^2 - 1}} = \frac{(r+1)(r^n - 1)}{(r-1)(r^n + 1)}$$

C. P.

[97284.]—**Geometrical Progression.**—An occasional controversy helps to keep us lively. I thank Mr. Burgess for the way in which he has stuck to his guns without raising any new point; but I really do not think he has understood my friendly criticisms. To begin with, I cannot agree with his first statement about meaning of my words, for to say that a biquadratic can be broken up into (real) quadratic factors certainly does not commit one to any statement about how to solve a biquadratic. To what I said about $r = x$ I have nothing to add. As to "C. P." (excuse liberties, "C. P."), I mentioned the form of his solution, not his formula. The word "practically" is to be noticed; frankly I do not think much is gained by the use of so many different symbols as "C. P." had in 96725, p. 189, and I prefer my own style, but that is purely a matter of taste; the argument used in a problem is not. Again, passing over the suggestion of some sort of unfairness, of which I can make nothing, I should like to say that I have in no way accepted the assumption of "A. O. S." that a and r are integers as you may see from the careful qualifying words "on his lines," nor have I later on ridiculed the same suggestion that x and r should be integers, unjustified though it be. On the contrary, I have been at some pains to point out, by a *reductio ad absurdum*, that the particular conclusion, "r is necessarily 2," could not be soundly based upon that assumption, as premised, inasmuch as the fact of x and r being integers would not exclude the values—

$$r = -1 \qquad x = \text{infinity}$$
$$r = 0 \qquad x = 315$$
$$r = 4 \qquad x = -57$$

where I have chosen one new example which may suit Mr. Burgess better than the others, as those seem to give offence by making the *reductio ad absurdum* too obvious. By the way, I do not at all scout the result $r = -1$, which is a possible algebraic solution of the problem, though arithmetically it is meaningless. What I do object to is that an equation, $r = \frac{315 - x}{150 + x}$, having more than one solution in integers, should be described as having one only. Finally (I have never had the chance to do so much contradiction before), I did not state or imply that a quintic can be expressed by quadratic factors, but merely that some quintics can be reduced to quadratics; the meaning of which is obvious in face of the fact that "Ontario" asks for a solution in quadratics, and Mr. Burgess implies that such a thing is impossible. May I at the same time point out to Mr. James Paris, without desiring to raise any further storm, that there is a flaw in his argument on this same point, namely, where he says, in reply 97284, p. 476, "It is certain that the algebraical division cannot produce a different quotient than the arithmetical one." If the falsity of this statement is not sufficiently shown by what I have written above, perhaps another example will make it clear? Suppose x stands for 7, then we shall find that $x^2 - 11x + 10$ divided algebraically by $x + 1$ gives us the quotient $x - 12$, and remainder 22; that is -5 and 22; but the arithmetical division gives -2 and -2. I cannot understand the end of the letter, though I should like to know what it means. Even if the Editor is long-suffering enough to print this rather personal communication, I shall probably not have time to tackle Mr. Burgess again, as I shall by Jan. 26 be teaching algebra to small boys, who will, most of them, never know nearly so much about it as Mr. Burgess does. If "H. T. B." wants something to criticise, let him look at the stuff at end of p. 477.

QUIVIS.

[97308.]—**Salicylate of Soda and Uric Acid.**—Permit me to thank "M. B." and "Glatton" for their replies. I am convinced, however, that the opinion expressed by "M. B." that gout is probably the only disease caused by uric acid is erroneous. For 31 years—i.e., between the ages of 21 and 52—I had suffered with severe frontal headaches, or migraine, arising from liver and dyspeptic troubles. They increased in duration and intensity as the years went by, until latterly the worst of them would last 18 hours, and during the last few hours of the attack the pain was almost unsupportable. About a year ago I learned from Dr. Haig's work on "Uric Acid as a Factor in the Causation of Disease" that salicylate of soda would cure these attacks by dissolving out the uric acid; and I may add parenthetically that I am indebted to one of Mrs. Hunter's letters (to whom "M. B." refers) in the "E. M." for my knowledge of the book, and I have since that time nipped every attack in the bud by a timely dose of 10 or 20 grains, sometimes repeated, of this drug. Occasionally a slight gastric upset has supervened, and I have wondered if any alkalies in my food had interfered with the action of the drug. My wife has also suffered with headaches from causes pertaining to her sex, and has cured them in the same way, and I feel very grateful to Dr. Haig for publishing for the general benefit this method of alleviating one of the many ills that flesh is heir to. In reply to "Glatton," our medical adviser put me on a diet for chronic rheumatism, which I found so ascetic that I am trying other methods before finally adopting it. I have read somewhere that continued treatment with salicylate of soda is injurious to the bony structure of the body and to the teeth, but no proof was given. I have also read that the "natural salicylate of soda," which is very much more expensive (ordinary salicylate being very cheap), is free from these deleterious effects. Authoritative information seems very difficult to obtain.

D. W. A.

[97319.]—**Belts.**—The reason an ordinary belt only lasts a short time is because the strain or pull is all on the outside edge of the belt—in fact, when the belt is laid on the ground, it takes the form of a semicircle, owing to one side being stretched more than the other. We have had two belts in four months, and the laces break nearly every day. If the laces don't give, the belt itself breaks. We are now trying a raw-hide belt, and it seems to be doing better, as it is more flexible.

W. MOORE.

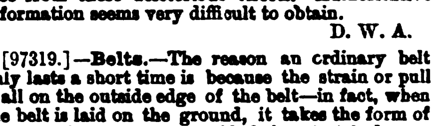
[97350.]—**Thermodynamics.**—To supplement the query under this heading, might I be permitted to add the following, which seems likely to amplify the original question raised by "T. B."? (1) It is said that "entropy" is the capacity factor, while temp. is the intensity factor of heat, and that—

$$\int \frac{dQ}{\tau} = \phi.$$

(2) Thermal capacity is quantity of heat expressed in heat-units required to raise temp. of any mass 1° C., while (3) specific heat is thermal capacity of unit mass. These definitions are all from standard books—e.g., W. Ostwald's "Lehrbuch d. Allg. Chem.," &c. Therefore, sp. heat × units of mass in body = thermal capacity. Now, suppose that dQ be expressed in units of heat, and unit mass of substance be taken, and suppose that $\tau = 1°$, then would the quotient in above formula = entropy = thermal capacity = sp. heat of that body? If not, why?

J. W. MELLOR.

[97355.]—**Mercury Interrupter.**—Take a piece of glass tubing (preferably combustion-tubing, it



A

B

being stronger) of the required diameter. Hold over a gas or spirit-lamp flame, as in Fig. A. If using a Bunsen burner, shut airholes, or the flame will be too hot. Turn tube round until it begins to soften, then draw it out, as in Fig. B. Break at d,

and select the best piece. Observe where the internal diameter seems to be a very little larger than the platinum wire. Break at this point, insert wire, and then fuse the glass round the wire by the blowpipe, so that the wire projects the right distance outside the end of tube, and also inside tube. Allow to cool carefully. Then it is ready for fixing in position. Before drawing out tube it must be bent to a right-angle, as advised in back numbers. Heat as above, where bend is required, and allow to bend into required shape by its own weight; allow to cool, then proceed as above. The co-efficient of expansion of glass and platinum being nearly the same, they are fixed immovably when cold. I have done the above often while testing in agricultural chemistry, to form convenient handles for holding wire for testing. A. DRYSDALE.

[97358.]—**Spherical Triangle.**—In the following I will use the symbols to which I am accustomed: Put C for P in your figure, A for Z, and B for S, and the sides opposite A, B, C, α, β, γ; these arcs of great circles corresponding to angles α, β, γ, at the centre of sphere. If we take any three points A, B, C, on a sphere, and suppose planes to pass through A B and the centre of sphere, and the same for B C and A C, and then suppose the sphere to disappear, leaving only the planes, we get a three-sided pyramid whose base forms a spherical triangle. Now if we open out this pyramid so that the three planes are in one plane, we get a fan-shaped figure M O N, such as I have drawn; and M O B, B O C, and C O N are the three planes or sectors having the angles γ, β, and α at their apices. Instead of using the capital Sigma to denote the sum of the arcs $\alpha, \beta \,.\, \gamma$, I will use the small Sigma σ to denote half the sum, then we have to prove that—

$$\cos. \frac{C}{2} = \sqrt{\frac{\sin. \sigma \,.\, \sin. (\sigma - \gamma)}{\sin. \alpha \,.\, \sin. \beta}}$$

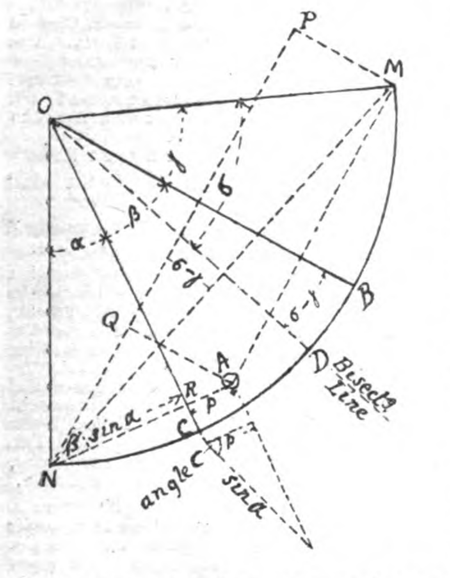
Square both sides, and remembering that—

$$\cos.^2 \frac{C}{2} = \frac{1 + \cos. C}{2}$$

we have to prove—

$$1 + \cos. C = \frac{2 \sin. \sigma \,.\, \sin. (\sigma - \gamma)}{\sin. \alpha \,.\, \sin. \beta}$$

Now if the two outer sectors were folded up into their former positions, the points M and N would meet at the point A, where the two perpendiculars on the turning lines meet, then (see small triangle) the



angle C will be seen. This small triangle is supposed to be an end view, and shows the angle between the two planes. It will be seen that $\cos. C = \frac{P}{\sin. \alpha}$ (R N = sin. α if radius = 1). Substitute this value of cos. C in the above equation, and after reducing we get—

$$\sin. \beta \,(\sin. \alpha + P) = 2 \sin. \sigma \,.\, \sin. (\sigma - \gamma).$$

Now, sin. α + P = N A, and angle Q N A = angle β, as the sides containing it are at right angles to those containing β; therefore sin. β (sin. α + P) = Q A. Again, B O D = $\sigma - \gamma$, and this = M N P for the same reason as in the last angle. N M, it will be seen, is 2 sin. σ, and therefore P M = 2 sin. σ sin. $(\sigma - \gamma)$. Now P M is evidently = Q A, so that the truth of the equation with which we started is proved.

Bath. M.I.C.E.

[97358.]—**Spherical Triangle.**—I suppose I may assume that "Fleur-de-Lys" is acquainted with the "fundamental formula" of spherical trigonometry. If not, its proof was given very fully and clearly by D. J. Carnegie, in "E.M." of June 23 last, which, I have no doubt, being so recent a number, could be easily procured. The fundamental formula is that in a spherical triangle A B C

$$\cos. A = \frac{\cos. a - \cos. b \cos. c}{\sin. b \sin. c}$$

But, by a formula of plane trigonometry—

$$2 \cos.^2 \tfrac{1}{2} A = 1 + \cos. A$$

$$= 1 + \frac{\cos. a - \cos. b \cos. c}{\sin. b \sin. c}$$

$$= \frac{\cos. a - (\cos. b \cos. c - \sin. b \sin. c)}{\sin. b \sin. c}$$

$$= \frac{\cos. a - \cos. (b + c)}{\sin. b \sin. c}$$

$$= \frac{2 \sin. \frac{1}{2} (a + b + c) \sin. \frac{1}{2} (b + c - a)}{\sin. b \sin. c}$$

$$= \frac{2 \sin. \frac{1}{2} \Sigma \sin. (\frac{1}{2} \Sigma - a)}{\sin. b \sin. c}$$

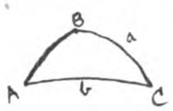
where $\Sigma = a + b + c$.

$$\therefore \cos. \tfrac{1}{2} A = \sqrt{\frac{\sin. \frac{1}{2} \Sigma \,.\, \sin. (\frac{1}{2} \Sigma - a)}{\sin. b \sin. c}}$$

Now apply this to our astronomical triangle Z P S, making P the angle A, and we have—

$$\cos. \tfrac{1}{2} P = \sqrt{\frac{\sin. \frac{1}{2} \Sigma \,.\, \sin. (\frac{1}{2} \Sigma - S Z)}{\sin. P Z \,.\, \sin. P S}}$$

which is the formula quoted by "Fleur-de-Lys." The reason of rejecting index 20 is to be found in the fact that the logs. of trigonometrical functions, as given in mathematical tables, are not the true



logs., but the logs. increased by 10, in order to avoid the use of negative integers. The tabular value of log. cos. $\frac{1}{2}$ P exceeds its true value by 10, which is doubled by the 2 in front, thus increasing that side of the equation by 20. The right-hand side of the equation contains four trigonometrical functions. Therefore it is increased by 40 above its true value. Hence, to preserve the equality between the two sides, 20 must be deducted on the right hand. The above proof of formula assumes a knowledge of the formula for the cosine of the sum of two angles, and of the formula for the difference of two cosines. These will be found, if necessary, in any book on plane trigonometry. If "Fleur-de-Lys" desires to pursue the study of these astronomical calculations, it might be worth his while to go systematically through a book of spherical trigonometry. Spherical trigonometry may not in itself be very interesting, but certainly becomes so when it is approached from the side of practical problems in astronomy. ARCTURUS.

[97359.]—**Flash Powder.**—Flash powders are necessarily explosive, and should at all times be used with great care. Keep all ingredients in separate stoppered bottles, and just before using weigh up each ingredient. Crush separately the chlorate, as this is apt to cake in lumps, and force has to be used to crush it, and when powdered thoroughly, incorporate with the other ingredients on a sheet of paper, using a bone or wood spatula, taking care to use no force whatever; and when mixed, lay it upon a sheet of tin-plate, and fire at arm's length, using either a piece of $\frac{1}{4}$in. or $\frac{5}{16}$in. iron rod made red-hot at one end, or a piece of touch-paper tied to a stick about a yard long. If you have to fire any quantity, lay it in a train, do not heap it up. The mixture named is rather a sensitive compound, and should not be kept ready mixed up, and, like all chlorate mixtures, becomes more sensitive to shock by keeping. If the querist will take care to always separately powder or crush each ingredient, and mix without contact with metals, and without force, mixing-up sufficient for immediate use only, the danger will be almost *nil*. He may also read paragraph on page 490 of your last issue with advantage. T. J. LENEY.

[97361.]—**Clock-Weight.**—Thanks to F. M. Mann. The pinions of my clock have twelve leaves, and I do not suppose that the other has more. Is it less expensive to plan the escapement for a large arc of swing of pendulum than for a small one? C. D.

[97371.]—**Prevention of Silver Oxidising.**—"If very clean" should read "if very black."

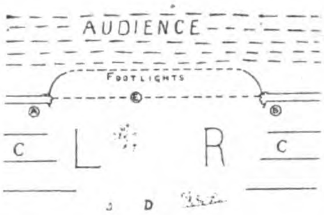
West Didsbury. M. COLE.

[97378.]—**Motor Tricycle.**—I do not know exactly the quantities and sizes of wires, &c., for making coil for tricycle motor, as I am not an electrician. Perhaps Mr. Bottone will oblige.

THE WRITER OF THE ARTICLES.

[97379.]—**Microscopic.**—To succeed in getting a clear picture of objects in each facet of a fly's eye the slide must be backed with black dull paper. Then the small flame of a petty powerful light—a 1in. paraffin burner will do—is arranged on one side of the stage, and the eye focussed until each individual image of the flame, on each individual facet of the eye, can be clearly distinguished. The photograph is taken whilst things are in this position. The exposure may vary, according to the power and proximity of the flame, from 8 to 60 seconds. To prepare a fly's tongue for mounting in Canada balsam, put the fly, when caught, bodily in good clean oil of turpentine. Let it remain there a week at least. It will then be found in good condition for mounting. Do not wash it too much, if you warm your Canada balsam. S. BOTTONE.

[97373.]—**Theatre.**—A is prompt entrance, where prompter sits, and where gas taps, &c., are situated; B is O.P. entrance—O.P., of course,



meaning opposite prompt; C are the scenery wings; D is back cloth; E is proscenium opening; R and L meaning right and left of stage facing audience. MAJOR.

[97380.]—**Manchester Dynamo.**—Mr. Joinson has omitted to state one very important item—i.e., the voltage the machine is required to give. The core discs are presumably of the plain drum type. If so, the bore of the pole-pieces should be $3\frac{1}{4}$in., and the winding for a shunt machine to give 50 volts 3 ampères at 2,600 revs. will be:—$1\frac{1}{2}$lb. No. 23 on armature, and 8lb. No. 21 on the fields.

A. H. AVERY, A.Inst.E.E.

Fulmen Works, Tunbridge Wells.

[97380.]—**Manchester Dynamo.**—Wind the armature with $\frac{1}{2}$lb. No. 24 silk-covered wire, and the field-magnets with 2lb. No. 24 d.c.c. This winding will enable the dynamo to give, when driven at about 2,500 revs. per minute, a current of 2 amps. at 15 to 20 volts pressure. Connect up in shunt. S. BOTTONE.

[97381.]—**Piston Speed.**—Generally multiply twice the length of stroke in feet by number of revolutions per minute of crank-shaft. High speeds give large expansion measures, smooth and uniform motion; require wider bearings and accurate balancing. REGENT'S PARK.

[97382.]—**Rats.**—I should not put poison down. I have heard that a good way to get rid of rats is to catch some and smear their coats with coal-tar (also the holes, if they can be found). Rats do not like that, and take their departure. It may be unkind to the caught rats, but returning to their haunts their friends quit, which I suppose will suit the object of the querist. A really good cat will soon clear any house of rats. They may go elsewhere, but they won't come where pussy is about. They fight shy of a good cat. I speak from some experience. S. R.

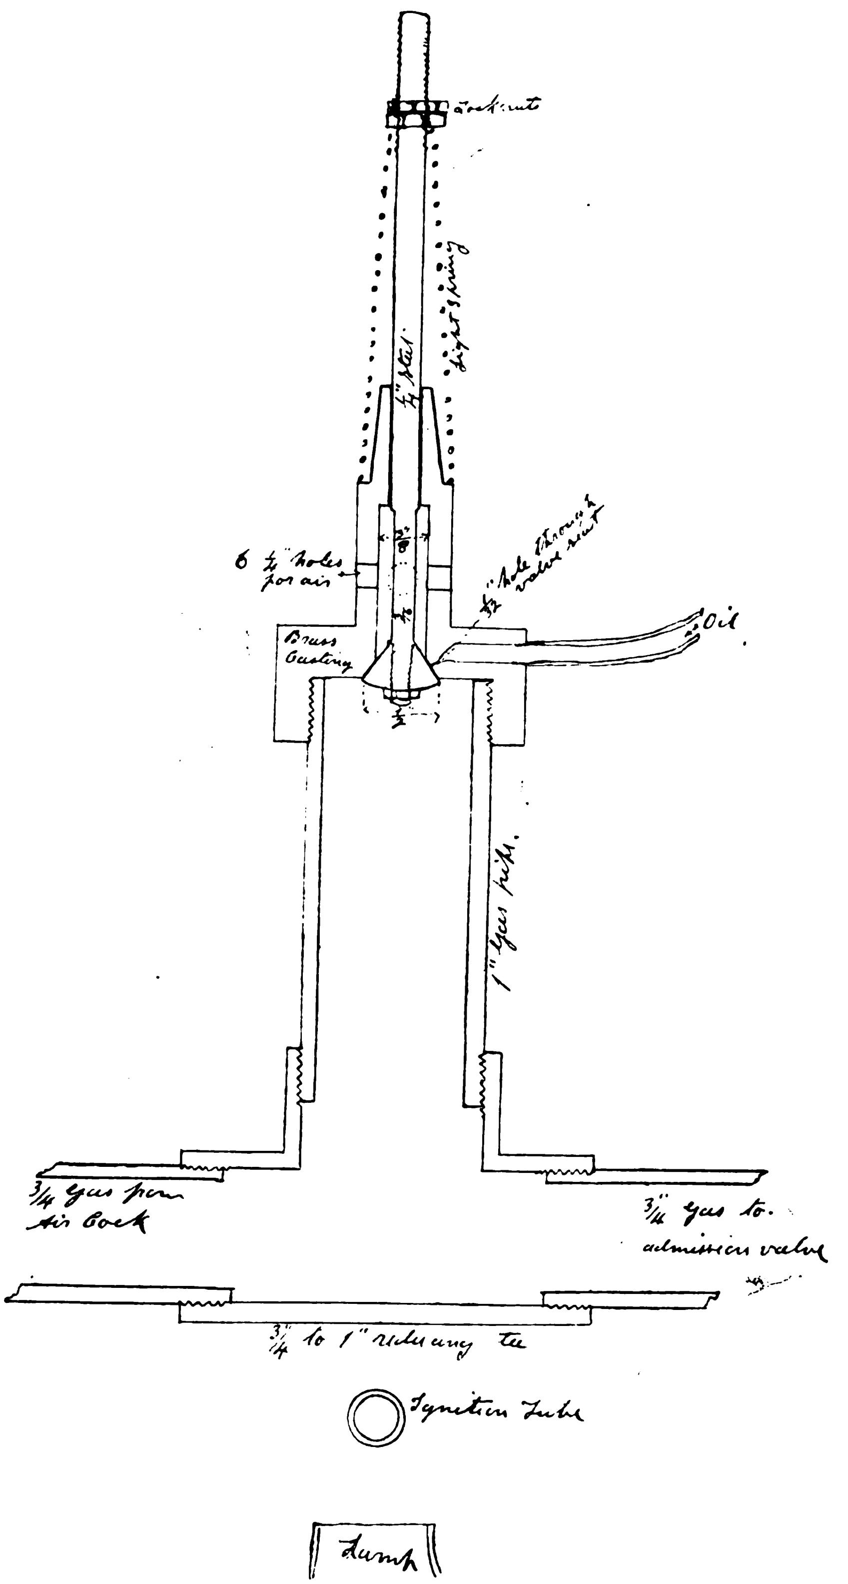
[97382.]—**Rats.**—A few drops of oil of rhodium on bait in trap entices them to their doom. Caustic potash, thin layers put into their holes, drives them away. Wafer corks cooked in grease in tracks, or sponge dipped in honey or molasses attracts them, gets in their fur, and tends to drive them away. Also, birdlime and oil of rhodium. Stiff mixture of common squill 2 parts, chopped bacon 3 parts, made into cakes and baked and placed in holes, will destroy them. REGENT'S PARK.

[97382.]—**Rats.**—A good dodge to clear a place of rats is to catch two or three in a trap, daub them well over with coal-tar, and let them loose near one of their holes, so that they shall make a bolt down the hole, leaving coal-tar wherever they run; stuff up the hole with broken glass, and you will have no more rats to trouble you. Don't tell your neighbours why they have so many more all at once. JACK TAR.

[97383.]—**Dynamo.**—To MR. BOTTONE.—In either case you will wind the armature with $\frac{1}{4}$lb. No. 22 d.c.c.; for shunt you will put 2lb. No. 22 on the two F.M.'s; for series only, you should use 2lb. No. 16 on the F.M.'s, while for compound you will lay on 1lb. No. 18 for the series coils, and over this wind 1lb. No. 24 silk-covered for the shunt coils. Speed about 3,000revs. per minute; output about 1 to $1\frac{1}{2}$ ampère, at 15 volts pressure.

S. BOTTONE.

[97384.]—**Storage Battery.**—To MR. AVERY.—I have not personally come across a similar case, but believe it to be a fault common to all cells of the Plante type. It is due to the plates gradually losing their "formation"; and charging in sulphuric acid solution alone is not sufficient to restore them. The cells would need special treatment in a solution the composition of which is the subject



of a patent owned by the firm in question. This self-same firm being, I believe, still in liquidation, it is a doubtful matter whether they are in a position to undertake the work of restoration.

A. H. AVERY, A.Inst.E.E.

Fulmen Works, Tunbridge Wells.

[97377.]—**Oil-Engine.**—If "A. C." will fit vaporiser as sketch to his gas-engine, it should work all right with oil. Vaporiser is easily made, mainly of iron gas-fittings. Sizes are right for 1H.P. engine. Should recommend separate lamp to heat ignition and vaporisers, as its oil-supply has to be under pressure. J. E. T.

[97386.] — **Drilling Gold Quartz.** — Harry Emanuel on "Precious Stones," alluding to drilling rock crystal (which may apply to gold quartz) gives: —Splinter of diamond is used with tool. In the case of cutting rock crystal, a copper wheel is used with emery, and, as he does not say otherwise, a copper drill is used. Fluoric acid also cuts rock crystal, and probably quartz. REGENT'S PARK.

[97387.]—**Frost on Windows.**—Thin coat of glycerine outside and inside of glass is said to check this. REGENT'S PARK.

[97389.] — **Series-Wound Motor.** — TO MR. BOTTONE OR MR. AVERY.—The following are the dimensions of one of my 3H.P. Lahmeyer-type motors, which will, to all intents and purposes, correspond to the type of carcase indicated in your sketch:—Armature, plain drum; core, 6⅝in. dia. by 7in. long, wound four layers deep with No. 20 S.W.G.; about 1,440 conductors; fields, 7in. bore; pole-pieces, 7in. deep by 5½in. wide by 3in. length of winding space; yokes, 2¾in. thick by 7in. long; series coils, about 300 turns No. 12 S.W.G., 150 turns on each bobbin; current required at full load, 12 ampères; speed, 1,800 revs.

A. H. AVERY, A.Inst.E.E.

Fulmen Works, Tunbridge Wells.

[97389.] — **Series-Wound Motor.** — TO MR. BOTTONE OR MR. AVERY. — Armature 6in. dia., 9in. long, wound with 9lb. No. 16 d.c.c., field magnet core of the shape figured by you, 12in. inside dia. 14in. outside dia., polepieces 5in. long, and embracing together ⅝ of the armature. Total length 9in., wound with 40lb. No. 10 d.c.c.

S. BOTTONE.

[97390.]—**Electro-Deposition of Lead.**—Lead can be deposited as a good adherent deposit, from a half-saturated solution of lead tartrate. The E.M.F. must not exceed 2 volts. If the solution is too strong bubbles of hydrogen are given off, and the lead deposit is spongy. A sheet-lead anode must be employed. To make the tartrate, precipitate the hydrated oxide of lead from the nitrate or acetate, by cautious additions of caustic potash solution; decant off the supernatant fluid, and dissolve the precipitate by the cautious addition of tartaric acid until all is dissolved. Add water to double the bulk. S. BOTTONE.

[97391.]—**Spun Glass.**—If a mass of soft glass is touched with a piece of solid glass and this latter quickly withdrawn, the soft glass is pulled out to a very fine thread, and if this thread is connected to the circumference of a wheel, the whole of the soft mass may be wound as a fine thread, provided heat of mass is maintained. See "Glass-Blowing and Working," by T. Bolas. REGENT'S PARK.

[97391.] — **Spun Glass.** — The only apparatus required is a wheel mounted on trunnions with a handle to turn it; a hot flame (spirit lamp or gas) and a rod of soft glass of the desired colour. The operator holds one end of the rod over the flame until it softens, pulls it out sharp, and whips the thread thus formed over the edge of the wheel, which he keeps rotating while the rod is still held in the flame. By this means, a continuous thread is produced. S. BOTTONE.

[97391.]—**Spun Glass.**—This is easily done. Two gas-jets fixed so that they both play on a rod of glass and keep it soft. Another bit of glass pressed on this and drawn away carries with it a thread of glass, the thickness of which depends on the speed at which it is drawn away. In practice, it is usual to lap the thread on a revolving drum or wheel so as to get an even pull. Spun glass is very nasty stuff to handle, as it is difficult to prevent small quantities getting into the lungs and eyes, where they do much damage.

West Didsbury. M. COLE.

[97392.]—**Tarnished Silver.**—Most likely by the sulphuretted hydrogen in room, which it cannot resist. If you care to varnish with transparent mixture use copal 1 part, oil of rosemary 1 part, absolute alcohol 2 to 3 parts; digest. Warm metal. Apply with soft camel-hair brush. Cleaned by rubbing with boiling solution of borax. Also with fresh concentrated solution of hyposulphite of soda, and polished if necessary, with buckskin. Trade cleaner of plate: Carbonate ammonia 1 part, water 4 parts, Paris white, 16; mix well. Apply to surface by soft leather or sponge.

REGENT'S PARK.

[97392.]—**Tarnished Silver.**—See replies in last week's issue at 97371. S. BOTTONE.

[97392.]—**Tarnished Silver.**—This is answered in reply 97371, same page as inquiry. M. COLE.

[97393.]—**Telescope.**—"F. B." may receive a dozen answers to this question, all of which may be right. But all practical astronomers will, I think, now admit that, given a definite amount to spend as stated, the best value can be obtained by deciding on a reflector with plain equatorial mount. An instrument of this kind, with four eyepieces and mirror 6½in. diameter, could be obtained, the mount being made in such a manner that divided circles could be afterwards added when required. This instrument would far supersede a 3in. achromatic, and prove a most convenient instrument to handle.

Corporation-street, Bolton. W. BANKS.

[97393.]—**Telescope.**—"F. B." cannot do better than get one of Messrs. Thos. Cooke and Sons 3in. educational telescopes. There are, of course, many cheaper and excellent makes in the market; but the extra few pounds will be well laid out in the superior finish and superb defining power of these instruments, which are guaranteed to bear the theoretical limit of magnification—a quality that few of the so-called first-class refractors sold really possess. An equatorial mount is doubtless an advantage for astronomical purposes, provided the telescope can remain a fixture outside under cover; but it adds considerably to the cost, and is by no means as handy as an altazimuth for all-round purposes. NORMAN LATTEY.

[97395.]—**Propellers.**—There is much in D. W. Taylor's "Screw Propulsion," of Whittaker and Co., and in Tomkins's "Marine Engineering," the first 1893, and the second 1896. The Patent Office would be sure to have literature, &c., and models—numbers at South Kensington, and in lectures (3) at Royal Naval College, 1885, by S. W. Barnaby, of Spons. REGENT'S PARK.

[97395.]—**Propellers.** — The "slip" of a propeller is the difference between the distance the propeller would advance in a certain time if the water formed an unyielding "nut," and the distance it does actually advance. Of course, if the

water were unyielding, the propeller would advance a distance equal to its pitch at each revolution; but in practice, the propeller always displaces the surrounding water backwards at a certain speed, and thus is said to "slip." The blades should revolve uniformly, and there is no "stroke" about them, much less an "intermittent" one.

R. H. PARSONS.

[97396.]—**Gassner Cell.**—See reply No. 97410 in this number. If the cell is a very large one and in good condition as far as regards zinc and terminals, it might be worth while, after having soaked the cell in water, as directed in the above-named reply, to squirt in the holes an ounce of saturated solution of permanganate of potash. A small glass syringe will do this well. When this has soaked in, the holes in the pitch must be sealed up again with a hot iron. S. BOTTONE.

[97398.]—**Climate of China.**—Is cold when compared to others in the same latitude. Pekin is as far south as Naples, yet the average temperature is 9° lower. The summers are hotter, and the winters colder, than in Western Europe in the same parallels. From November to February the weather is usually intensely dry and cold; March and April bring fogs and a milder temperature; in May rains are abundant; from July to September the weather is intensely hot, while hurricanes and typhoons may be expected; in October there is the gradual autumnal preparation for winter. S. BOTTONE.

[97399.]—**Wireless Telegraphy.**—Any large mass of metal lying between the transmitter and the receiver seriously interferes with the inductive influence of the electric wave. Even a tea-tray held in front of the receiver will in most cases prevent its acting. Induction can only take place through insulators or dielectrics: hence the disturbing effect of a metalliferous mountain.

S. BOTTONE.

[97399.]—**Wireless Telegraphy.**—Because the iron in the strata of the mountain absorbs the electrical waves which are propagated by the transmitting instrument. Thus the iron mountain is acting as a shield to the receiver. If querist has an apparatus of his own. I should advise him to put a large sheet of metal between the transmitter and receiver, and observe the results.

A. STAMMWITZ.

[97401.] — **White Brass.** — The special alloy mentioned by the querist is definite—it is a trade name for a very good bearing "brass." It must be understood that the "linings" of bearings are invariably called "brasses" in shop technology, and they may be Babbit metal or "white brass," or any other name. So far from there being "only one kind of brass," there are several—the proportions of copper and zinc are different, and the more zinc, the whiter the "brass." It is certainly a "composition" whatever it is; but I think the answer to the query is that all "linings" are called "brasses," and the alloys vary. M. T.

[97401.]—**White Brass.**—Magnolia metal said by Dean to be: Lead, 78; antimony, 21; iron, 1. White brass: Alloys of copper and zinc, with less than 45 per cent. of copper, cease to have yellow colour. Alloys from 40 down to 30 per cent. of copper are silver white. These are rather brittle, and fail generally under rolling, wire drawing, and pressure. White metal: Copper, 3; tin, 90; antimony, 7. Copper, 5; tin, 85; antimony, 10. See "Mixed Metals," A. H. Hiorns (Macmillan and Co., 1890). REGENT'S PARK.

[97400.]—**Dynamos in Parallel.**—Certainly.

S. BOTTONE.

[97400.] — **Dynamos in Parallel.** — Yes, certainly, provided the voltage of each machine is kept exactly alike. Instructions for coupling together have been given many times in back numbers. A. H. AVERY, A.Inst.E.E.

Fulmen Works, Tunbridge Wells.

[97400.]—**Dynamos in Parallel.**—It is possible to work your two dynamos in parallel, but you must take care that the voltage of both is kept equal and constant.

Dudley. WEBSTER MICHELSON AND CO.

[97401.] — **White Brass.** — The brass-finisher who had not heard of white brass must be a curiosity. Its trade name is Parson's white brass, and it is composed of tin 68, zinc 30·5, copper 1, and lead 0·5. It is, except in colour, very similar to ordinary yellow brass, and is machined with the same sort of tools. Magnolia metal is patented, and must be bought in ingot form from the Magnolia Company. It is claimed for it that it is to some extent self-lubricating. J. H. H.

[97401.]—**White Brass.**—The brass-finisher is right, as far as his knowledge of his own trade takes him; but what is often called "white brass" in an engineer's shop is more properly Babbit metal or some similar alloy. It is doubtless called "brass" because we always speak of bearings as "brasses," although they may be made of gunmetal, phosphor-bronze, or anti-friction metal, like magnolia or Babbit metal. HYDE PARK.

[97404.] — **Wilson's Four-Cylinder Locomotive.**—Robert Wilson and Co., of Newcastle, built the engine named Stockton for the Stockton and Darlington Railway Company, being No. 5 in the official list of that line, and it commenced work on March 15, 1826. This engine ran upon two pairs of cast-iron wheels of 4ft. diameter, having a wheel-base of 5ft. 9in., the boiler being 13ft. long and 4ft. diameter, having one fire-flue running throughout. Each pair of wheels was perfectly independent, being actuated by a pair of cylinders, the crank-pins being at right angles to each other. Steam could be applied to either or both pairs of cylinders at pleasure, and the two sets of valve-gear could be reversed independently. The exhaust steam was discharged into the chimney by two blast-pipes, one for each pair of cylinders. This engine, having run for a few months, in October, 1826, came into collision at Stockton, when the four cylinders and all the overhead gear were smashed, and the official list, dated December 31, 1826, states, No. 5, "This engine is not now in use"; and so it remained until April, 1827, when Mr. Hackworth, the company's locomotive foreman, rebuilt this engine. He lengthened the frame, added a new pair of wheels, thus converting it to six wheels all coupled, and placed a return-flue tube, in the old boiler, removed the four broken cylinders, and adopted two new ones. The original engine had one blast-pipe for each pair of cylinders, and Mr. Hackworth retained the same arrangement for the new pair of cylinders. The engine thus altered and renamed Royal George, No. 5, was put to work in October, 1827. The original working drawing of the Stockton was shown at the Chicago Exhibition of 1893, and a copy of it either has been, or shortly will be, on view at the South Kensington Museum.

CLEMENT E. STRETTON, C.E.

Leicester, Jan. 13.

[97406.]—**Ulcer in Stomach.**—The cause is something wrong in the system, most likely decomposed matter taken in food. If it be ulcer only, it can be cured. I had a servant suffering from it, and took him to a very clever medical man at Birmingham, who said the way was to let nature cure it, and in the mean time support the patient with nothing but milk, which, he said, contained all the elements necessary to support life. The patient visited the doctor at intervals for some months, and at last the doctor allowed him to add a little of Polson's corn-flour to the milk. After another interval he allowed him a square inch of meat, and so on. The man got quite well. He did his work as usual all the time. From the description which "Tempus Fugit" gives, there seems a probability that it may be something worse than ulcer. Two or three drops to each ounce of hot water of the tincture of Hydrastis canadense, and of this take a teaspoonful, hot, frequently, would help; but it is too serious a case for amateur doctoring. It ought to be under the constant superintendence of an experienced medical man, or go into hospital.

W. A. A.

[97406.]—**Ulcer in Stomach.**—I am not a medical man, but some years ago, when about fifty years of age, I felt constantly a very disagreeable—not actually painful—sensation in the stomach, as if there was an open sore there. Without medical advice I took two or three times a day half a glass of limejuice with a little water in it, and gradually kicked off the complaint, whatever it was. After drinking the limejuice the mouth should be rinsed with water, so that the teeth may not be injured.

N.

[97409.]—**Axle to Motor Car.**—If querists would not be so sparing of information they would get better replies. How can one advise the size of axle without particulars as to weight axle is to carry? I have seen 4H.P. cars of 5cwt. and of 25cwt. Obviously the same size of axle will not do for both. The differential gear could be placed between spring and wheel hub, but will require to be specially designed, and would then be working under rather trying conditions.

THE WRITER OF THE ARTICLES.

[97410.]—**Dry Battery.**—No, it can *not*.

HYDE PARK.

[97410.]—**Dry Battery.**—The manner in which this question is put proves that the querist does not understand the conditions involved in joining a dry battery of comparative low resistance to a (I presume) public supply of electricity. If this is attempted, a considerable resistance in addition to the battery should be inserted, along with an ammeter to measure the current, and the resistance withdrawn until the current required is obtained. This should not exceed one ampère. Of course, except the supply is a continuous-current one, it is useless attempting anything.

11, Corporation-street, Bolton. W. BANKS.

[97410.] — **Dry Battery.** — These batteries generally fail in consequence of the drying-up of the moisture in the paste. The contacts also get corroded between carbon and terminals. If they are worth renovating, which is doubtful at their present price, the quickest way is to remove the terminals for cleaning up, to make two ¼in. holes through the pitch with a hot wire, and then stand the cells for 24 hours in a pailful of water. Remove, dry, seal up the pitch again with a hot iron, and replace the terminals. You can put a little charge in from a dynamo, if you connect + to +, but it is not much good. S. BOTTONE.

[97411.]—**Edison Lalande Battery.**—This consists in a plate of compressed black oxide of copper as one element, and a plate of zinc as the other. The exciting fluid is a solution of caustic potash in water, of which the usual strength is 1 to 5 by weight. To prevent this from absorbing carbonic acid from the atmosphere, the solution should be covered with a layer, about ½in. thick, of heavy petroleum oil (vaseline oil). To my mind, these cells are not worth the space they occupy.

S. BOTTONE.

[97412.]—**Meridian Passage of Stars Locally.**—I think quite differently to "W. B. D." respecting this matter. Surely anyone possessed of a transit or other instrument, and requiring this information, must know the difference between "mean time" and "local mean time." "Mean time," or "Greenwich Mean Time," are the terms used generally, local mean time never being referred to except in connection with the difference in longitude of places compared to Greenwich.

Corporation-street, Bolton. W. BANKS.

USEFUL AND SCIENTIFIC NOTES.

THE number of men employed in building locomotives in this country has increased 10 per cent. during the year just closed.

ACCORDING to the correspondent of the *Standard* at Hamburg, the Hamburg-American Steamship Line is about to introduce a new kind of fuel for its freight steamers now building for the Eastern Asia line. The fuel consists of semi-fluid petroleum, which is imported from Borneo in large quantities. It is not liable to spontaneous ignition at high temperature. The new method of firing will permit of considerable economy of space and labour.

IT is estimated that Great Britain, the United States, and Germany have from two-thirds to three-fourths of the world's business in metals, shipping, finance, imports, exports, &c. These countries produce 77 per cent. of the world's make of pig-iron; 80·8 per cent. of the steel; they take 75·2 per cent. of the world's consumption of lead; 73·1 per cent. of the copper; 67·5 per cent. of the spelter; and 67·2 per cent. of the tin.

IN the vicinity of Australian streams may be found large and beautiful dragon-flies, often of considerable size; while everywhere, during the warmer months of the year, the ceaseless hum of the cigale reminds the traveller of a similar insect experience in Italy. Native honey-bees are plentiful in many places, and are easily recognised by their small size, being little larger than the common house-fly. Mosquitoes are practically unknown in the dry interior, but their place is taken by the sandfly, an equally mischievous insect. There are spiders of all sizes, a few being poisonous, but their webs are generally of a most fanciful character.

AN electrical system for working water-tight bulkhead doors was described at the recent meeting of the American Society of Naval Architects and Marine Engineers. A bulkhead door sliding in frames is arranged with a brass rack on one face. A pinion which gears in this rack also gears with a second horizontal shaft which is driven by worm-gearing. An electric-motor of 1H.P. is direct coupled to the worm-shaft. The weight of the door complete with the operating apparatus is 1,383lb. The sliding-frame and the guide-frame of the door are arranged so that the last ½in. of the travel sets up a wedge action, which forces the door against its seat. The electric-motor is compound-wound with relatively weak shunt-coils. The circuits are so arranged that when raising the door the series-coils only are used, while when closing the door the shunt and series-coils are both in circuit.

Coal and Gold.—The output of coal throughout the world last year is computed at 662,820,000 tons. In these totals Great Britain figured for 202,054,516 tons; the United States for 196,405,953 tons; Germany for 130,928,490 tons; France for 32,439,786 tons; Belgium for 22,075,093 tons; Austria and Hungary for 35,039,417 tons; Russia for 12,862,033 tons; and all other countries for 30,960,712 tons. The production of gold throughout the world during the last ten years has been as follows:—1888, £22,039,200; 1889, £24,696,000; 1890, £23,769,740; 1891, £26,131,200; 1892, £29,330,300; 1893, £31,498,960; 1894, £36,235,120; 1895, 39,752,720; 1896, £40,336,460; 1897, £47,500,960; and 1898, £57,485,720. It will be seen that the production of gold has increased with gigantic strides during the past five years. This is largely attributable to the revival and progress of gold-mining industry in Australasia, and also to the astonishing advance made in the Transvaal.

UNANSWERED QUERIES.

The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered, are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.

Since our last "Quivis" has replied to 96878, 96919, 96969, 96967; Webster Michelson and Co., 97162.

QUERIES.

[97413.]—**Electrical.**—I shall be glad to know what sort and size accumulator to use with induction coil, having as primary 10oz. of No. 16 s.c., and as secondary 2¼lb. of No. 36 s.c., in two sections. Also, what length of spark should be expected, with suitable condenser?—X.

[97414.] — **Hand-Camera Construction.** — At what distance ought I to place the lens of a fixed-focus hand-camera from the diaphragm over which shutter works? Have seen hand-camera with lens as far back as 1½in., and bellows-camera with barely ⅝in. between.—A. H. H.

[97415.]—**Automatic Boiler Feed.**—Will R. Hudson kindly see if he has made a mistake, as I have searched through three volumes of Salomon's "Electric Lighting," and cannot find it?—J. A. C.

[97416.]—**Leclanche Cells.**—I should be grateful to "Sigma" for advice on the following:—I lately purchased a dozen of the above-named cells of the sealed agglomerate type. The zincs are rod-shape, about ⅜in. diameter, standing in porous pots. I am disappointed in their action. (1) Shall I get increased intensity of current by substituting sheet zinc bent in cylindrical form for the rod? (2) If so, will it be beneficial to amalgamate the plates? (3) What description of paint should be applied to the outer surface of sheets? (4) Should the agglomerate carbons be clothed in canvas to avoid rapid polarisation? Other cells in my possession with the latter arrangement give most excellent results.—C. R. O., Hants.

[97417.]—**Micro-Metallurgy.**—How can I prepare and mount specimens of iron, steel, brass, and other metals for microscopic examination? Also, what would be the best kind of microscope, eyepieces, &c., and probable cost of same?—MAX.

[97418.]—**Microscopical.**—Will someone please give a formula for finding magnification of the image formed by the object-glass at various distances from it? For instance, if the initial magnification of the o.g. on a 10in. tube is 40 diameters, what would be the magnification of an image formed by it on a screen at, say, 33in.? Of course, I mean without an eyepiece.—VERINDER.

[97419.]—**Moisture.**—Can I learn anyway how to drive moisture from coagulated blood and starch waste economically on the large scale, and similar substances containing about 70 per cent. water? Can an idea be had of cost by steam heat (which is preferable), and also from a flame heat like a kiln?—GEMINI.

[97420.]—**Swiftograph.**—Some years ago I saw a system of shorthand called "Swiftograph," invented, I believe, by a Mr. Faut. Abbot. Can any reader give me his address, or tell me where the *Teacher* may be purchased? I shall be glad of any information.—HAYDON BARRY.

[97421.]—**Boiler.**—I have got a ½H.P. steam-engine. Could any reader tell me how to make a boiler for same, one that would make steam fast? Please state size boiler should be for half-horse engine.—BLACKSMITH.

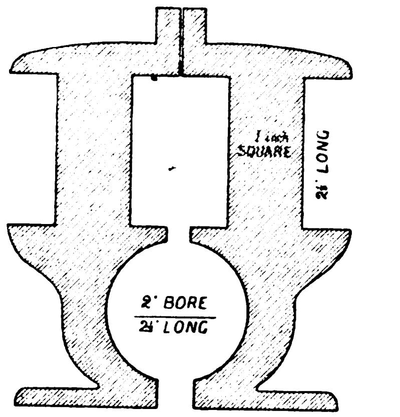
[97422.]—**Psoriasis.**—Would "Regent's Park," who suggested remedies in reply 97335, kindly say whether same would suit what I have been told is "psoriasis," as the effect seems to be the same in both cases—viz., quantities of scurf? I have tried many things, but none seem of any use, and hair is fast falling off.—A FELLOW SUFFERER.

[97423.]—**Mercury Contact-Breaker for 10in. Coil.**—Will some reader please help me out of the following difficulty? I have made a mercury interrupter, motor-driven, but am troubled with the mercury becoming one mass of small globules, and thus spoiling its efficiency. I put paraffin oil on the surface to prevent oxidation. Is this right? I have seen methylated spirit recommended. Is there no fear of its firing? Should something be mixed with the mercury? Shall be glad of any help. Will be quite ready to make another, if I know where the fault lies.—INTERRUPTER.

[97424.]—**Paralysed Hand.**—I wish for advice on what seems a sort of paralysis of the thumb. First, I should say that I have consulted a good doctor, who gives me little comfort and discourages my going to a specialist in nervous diseases. The thing has been coming on very gradually for a year or more, and now there seems no feeling in the end of thumb. Worse still, it seems to be creeping up the arm, and down to the forefinger. I have tried the ordinary galvanic machine, of which the doctor does not think much, and, of course, frequent and vigorous friction. Age 74, good general health, little beer, and no tobacco. Can anybody who has had a similar experience advise?—R. S.

[97425.]—**Eyepiece.**—Is there any objection to using a compound microscope as an eyepiece? If not, where should it be placed in the cone of rays from o.g.?—MICRO.

[97426.]—**Charging Dynamo.**—I have dynamo castings as per drawing inclosed, and I wish to make it



for a charging dynamo. Could Mr. Bottone or any other kind reader give me the full instructions as to wire in quantity, and the best armature, &c.? Field-magnets 1in. square, 2½in. long; armature tunnel 2in. bore, 2½in. long. What would be the voltage and the ampères?—G. B., Aston.

[97427.]—**Hard Composition.**—Can any reader inform me of a cheap composition which can be moulded, something like guttapercha, and, when hard set, nails can be hammered in, similar to timber?—BOLTER.

[97428.]—**Grease.**—I have a quantity of old hot-neck grease in which there is a quantity of gritty matter. Can any of our readers give me a recipe to refine this of all such matter?—BOLTER.

[97429.]—**Tin Scale.**—I should like to know the best means of bringing back to its metallic state a quantity of tin scale which I have? The scale is from tin scrap.—BOLTER.

[97430.]—**Power for Lathe.**—What would be the power required to drive a 5½in. screw-cutting lathe, and, say, an emery-buff as well?—B. M. S.

[97431.]—**Gas-Engine Valves.**—Can any reader of "Ours" tell me the best way to grind the valves of a gas-engine? They are iron valves on cast-iron seats, which are very hard and awkward to get at.—C. W.

[97432.]—**Double Star in Cetus.**—Can any reader inform me what is the name of the double star, which I find in position (estimated) R.A. 1h. 35m.. Decl. – 12°? I do not find this star in Webb, though it is just visible to the naked eye.—A. G. BATLEY.

[97433.]—**Dynamo.**—I have a dynamo, Manchester type. The fields are wound with 11½lb. of No. 22 wire on each, and 6¾lb. No. 18 on armature. I bought it as a failure, and rewound the armature, and got a fairly good light, but it nearly pulls a four-horse engine up. Are the proportions of wire right? And what candle-power should I get out of it if properly wound, and what horse-power should drive it?—W. S. LESLIE.

[97434.]—**Spherical Triangle with Side >90°.**—Will "F.R.A.S." or "Arcturus" kindly help me in the following question? In solving lunar distances, my method is to find from observed distance, and apparent zenith distances of moon and star or sun as data, the angle at Z (as also those at M and S), by the usual method—

$$2 \log. \cos. \tfrac{1}{2} Z = \log. \sin. \tfrac{1}{2} \Sigma + \log. \sin. (\tfrac{1}{2} \Sigma - M S)$$
$$+ \log. \operatorname{cosec.} Z M + \log. \operatorname{cosec.} Z S - 20.$$

Then, with angle at Z, and the two including sides got from true altitudes of moon and sun or star, to find the true distance by formula—

$$\tan. \tfrac{1}{2} M S = \sin. \tfrac{1}{2} (M + S)$$
$$\times \tan. \tfrac{1}{2} (M Z \sim S Z) \div \sin. \tfrac{1}{2} (M \sim S).$$

The method is cumbrous; but as my object is more that of practice in spherical trigonometry than actual determination of time, it has advantages over the versine method. My difficulty at present is, what happens when the triangle exceeds the limits of a quadrant?—e g., in the lunar given in Stebbing, the distance M S (obs.) is 98° 44′ 49″, and the quantity ½ sum of sides in Formula I. is 101° 14′ 3″. Is the log. sin. of its difference from 90° taken for log. sin. $\tfrac{1}{2}\Sigma$? If so, is the difference again used in log. sin. $(\tfrac{1}{2}\Sigma - M S)$?—FLEUR-DE-LYS.

[97435.]—**Electrical Power.**—I have a workshop situate 500 yards from a large lighting and power station, where the engines collectively are about 5,000H.P. The ground is broken gravel, with an underground stream about 20ft. from the surface. I have good reason to believe that a considerable amount of power is allowed to run to waste. Is it practicable to tap the ground and obtain, say, 40H.P. from the waste, and how can I ascertain if there is any electricity beneath my workshop? I am an engineer, and have not studied electricity; but if there is any probability of obtaining either light or power from this source, I will obtain it.—ECONOMY.

[97436.] — **Stamping Notepaper.** — Will some reader kindly tell me how to make the ink required for stamping notepaper by means of a die, and how to apply it to the die so as to adhere to the indented surface, as it is not, of course, applied to the raised letters, as would be the case with type? Any information will oblige.—R. A. R. BENNETT.

[97437.]—**Dew on Object-Glass.**—I should feel obliged if some of your correspondents would kindly inform me what is the best way to remove the dew from the object-glass of my telescope—whether wiping it off with a very soft cloth is harmful, or should it be allowed to dry off? The telescope is a 5in. refractor, and when in use I avoid the deposition of dew by using a dew-cap; but, as I have not a telescope-house, I have to take it indoors at night, and, although I put on the brass cap before removing the telescope, a deposit of dew occurs, owing to the warmer temperature of the house.—W. G. T.

[97438.]—**Gun-Cotton.**—What chemicals are employed, and what is the process of the manufacture of pyroxylin or gun-cotton? Information will greatly oblige.—H. M.

[97439.]—**Gauge Sticking.**—How can I alter my steam-gauge from sticking (Bourdon's patent)? It will move a few pounds at once with a jerk. Can it be put right, or shall I require a new one?—N.

[97440.]—**Governing Engine.**—I have an old-fashioned portable engine by Burrell, and our work is very irregular, and it is governed by the old-fashioned governor and throttle-valve. Can anything be added to it to make it more regular? One minute it has all it can do, and the next nothing. I have a small governor by Tangye. Could I add that or anything to valve-rod by link or so? Any information would be thankfully received.—ALABAMA.

[97441.] — **Enlarged Tonsils.** — Will Mr. Gerard Smith, M. B. (Galway), or any other medical reader give me a little advice respecting the following? One of my children was about two years ago suffering from enlarged tonsils. The doctor gave us some lotion with which to paint them, and this seems to have effected a cure; but on taking her to another doctor lately (having removed to another part of the country) he says she has a growth of some kind in her throat, which he wishes to take away, but he declined to say if this would be perfectly safe, or if it would be a permanent cure. The child (female) is eleven years old. She is getting very thin in body and limbs, takes her food badly, and takes cold very easily. What I should like is the opinion of the above-mentioned correspondents as to whether an operation is safe, and if it would be likely to result in a cure. Any advice as to suitable medicine or food would also be thankfully received.—QUI VIVE.

[97442.]—**To "F.R.A.S."**—Will "F.R.A.S." and other competent gentlemen kindly give me a little information on the subjects mentioned below:—(1) What does "the theoretical limit of power" for telescopic apertures mean? Why is 100 for each inch the theoretical limit? (2) I should like to know the exact formulæ for finding equiv. focal length of compound eyepieces. (3) When it is stated that the field of view decreases as the power increases, does it mean that the field of view itself actually decreases, or that objects are so magnified as to leave no room for anything else in the field? I thought the latter was limited by the stop. (4) How can I become a member of the B.A.A.? Is an introduction by a member necessary? What is the subscription, and what advantages accrue?—POLARIS.

[97443.]—**Face-Plate.**—Having made a model of a 24in. diam. face-plate for 6in. centre gap lathe, I got it cast, and find it weighs 150lb., or more than 1cwt. 1qr. My lathe is a heavy English screw-cutting one, by a first-class maker. When I come to turn this face-plate up true on the lathe, will it bend my mandrel? Must I discard it as too heavy? The makers' only weighs 40lb., but is only 20in. diam. Is it not safe to use a larger plate than 20in. on a 6in. lathe? Shall I bend my saddle if I turn up the large plate, as the saddle will project about 3in. over gap? I shall be very glad for a reply.—C. W., Hull.

[97444.]—**Tank Sinking.**—A rectangular iron tank, 80ft. by 20ft. by 9ft., floats at a draught of 4ft. A hole 1ft. square is made in the bottom. In what time will the tank sink? Take the coefficient of discharge as 0·6. Greenhill's "Hydrostatics," p. 463, gives 26min., which appears to be wrong.—NAVY.

[97445.]—**H.M.S. "Revenge."**—Where can the results of the rolling experiments on H.M.S. *Revenge* be read?—NAVY.

[97446.]—**Deflection of Oak Beam.**—An oak beam 16ft. long, 6in. broad, and 8in. deep is fixed down at its ends. A mass of 1,000lb. moving with a velocity of 3ft. per second impinges perpendicularly on the beam at its centre. What will be the amount of deflection caused?—NAVY.

[97447.]—**Cement.**—Wanted, cement for a mirror on china, to stand boiling-water. Can any of "ours" kindly tell me of a cement for above?—ALBERT SMITH.

[97448.] — **Galvanometer.** — Will some qualified reader give a short reply how to test Leclanché and other batteries with a galvanometer wound for quantity and intensity, and what the reading for a new one-pint Leclanché should be? Also, what is the proper definition or value of figures to which the needle is deflected? Anything of this sort would be more instructive and useful than a paper war as to 20th century and reasoning out the thinness of the that and the thusness of the why, or showing the difference between Tweedledee and tweedledum, Noah's Ark, ether, and destruction of Sodom.—NEW YEAR.

[97449.]—**Velocity of Sound.**—All the textbooks on Sound state that the velocity of sound in air (neglecting La Place's correction) may be calculated from the formula—

$$V = \sqrt{\frac{E}{D}}$$

where V = velocity, E = elasticity of air, D = density of air. Result is given as 920ft. per second. Will some reader perform this calculation?—ACOUSTICS.

[97450.]—**Drum Armature.**—I have a drum armature which gives 35 ampères 65 volts, the wires of which have got rubbed on the pole-pieces and worn thin. Can I rewind the faulty coils without undoing all the others? In Mr. Bottone's book on winding a drum armature,

it says the armature should be given a half-turn on the completion of every coil. Does this mean backward and forward, or continuously round?—D. A.

[97451.]—**Commutator.**—I wish to fix a new commutator on spindle. 32 sections, but cannot keep the sections straight. They twist round out of line when tightening the clamping-nut. How can I obviate this? Can the mica insulation be bought of a uniform thickness?—DRUM ARMATURE.

[97452.]—**Showcase.**—I have a showcase at street-door with flue electric lamps in. Can anyone tell me how to prevent the moisture coming on the glass? In damp weather it quite obscures the view. I have tried boring holes, but it makes the annoyance worse.—SHOWCASE.

[97453.]—**Motor-Car.**—I am making a small car for trade. Would "Country House" say if trade cars have to pay a license? If so, should I run any risk of running it to another shop to finish, thirty miles apart by road?—S. P.

[97454.]—**Overtype Dynamo.**—Will either Mr. Bottone or Messrs. Webster Michelson give me dimensions for overtype dynamo, compound wound, cog-ring armature, with cast-iron field-magnets, to light eighty 16c.p. 110-volt lamps? Also, the dimensions for a machine to light three 16c.p. 55-volt lamps?—LIDY.

[97455.]—**Alloy.**—Will some reader kindly tell me of a suitable alloy (aluminium) for making crank-cases, &c., for tricycle motors, with a few hints on casting, &c.? I am told pure aluminium is useless. Also, where can I obtain it, and what is the price about? I have a large brass furnace at my disposal.—LANKY.

[97456.]—**Launch.**—I have a fast rowing-boat for open sea work, 18ft. long by 4ft. 2in. beam, with a depth of 2ft. 4in., into which I wish to put an oil-engine, as fitting the screw in the usual way would mean rebuilding the stern of the boat. It has occurred to me that the screw-shaft may be brought out by the side of the stern-post. What is the minimum power of engine that should be put in her to do useful work? and also size and pitch of screw, which should not project below the keel, as the boat has to lie on the ground? Would a ½H.P. engine be of any use? One man sculling can send her along fast.—NAVIGATOR.

[97457.]—**Stopping Down Object-Glass.**—I would like to ask Mr. Norman Latey if his fine 4in. Cooke refractor has a stop near the object-glass, and its diameter. In my own 4in. there is a stop 12in. or 13in. down tube, contracted to an aperture of about 2½in., and one or two further down the tube. Now, I would like to ask any reader if my object-glass is more stopped down than it should be for one of the finest quality. I know the definition of the o.g. is very fine under high powers, and when I first saw the half-moon in the 4in., coming from a 3in., I was amazed at the difference. I may say the 4in. is a cemented o.g. of 6ft. focus, with the thick glass to the front.—O. G.

[97458.]—**Observatory.**—Will any reader inform me what is the smallest workable observatory with dome roof for a telescope of above dimensions—a 4in., of 6ft. focus. Most of the amateur observatories I have noticed in "Ours" have been of wood. Would not the ordinary frilled galvanised iron do at least for the square part? What size of dome would be necessary? Height of tripod 5ft. Could anyone inform me of probable cost of such a house?—OBSERVATORY.

[97459.]—**Deafness.**—I am a woman dependent on my own exertions, and am become excessively deaf. I have had the best of medical advice, but in vain. My occupation has been that of governess and housekeeper. I have read of an ear-telephone in *Pearson's Weekly*, but can obtain no information from the editor. An ear-trumpet fastens the hand. Is there such a thing as an ear-telephone? Is effectual aid possible for deaf workers—those who cannot afford to go in for a training? Do, please, help me if you can, by information or suggestion.—ANNE.

[97460.]—**Oil-Engines.**—Could any reader of the ENGLISH MECHANIC inform me, through the medium of that paper, how does the oil, after being vaporised, enter the cylinder in the Crossley and Blackwood oil-engines without being ignited in the vaporiser through which it first passes, for I noticed the lamp is underneath the vaporiser, and the vaporiser red-hot; and, also, where does the air mix with the vapour after entering or before entering the cylinder, and how does it ignite after entering cylinder, and not before, for the vaporiser is much hotter than the cylinder, and what prevents it? Kindly explain by means of a diagram?—CYMRO.

[97461.]—**Azimuth and Altitude.**—"F.R.A.S." would greatly oblige if he would apply a recent answer to the finding of the azimuth and altitude of a star of given R.A. and Decl., being also given the latitude of the place and hour of observation. *Whitaker's Almanack* available.—H. B.

[97462.]—**Vibration.**—The railway runs along at the bottom of my garden, and when heavy luggage trains are passing we are much annoyed with the vibrations. If I were to have a deep trench dug completely across, would it prevent the vibrations being felt? If you think it would, will you kindly say how deep the trench should be? My ground is 60ft. wide, and the house is about 135ft. from the metals. The house is an ordinary eight-roomed house, about 30ft. to ridge.—VIBRATIONS.

[97463.]—**Boiler.**—Would any reader versed in boiler experience say whether a $^3/_{16}$in. plate would be strong enough for a tube-plate, size 24in. by 15in., drilled with 100 1in. holes for tubes, the plate to be supported by six screwed tube-stays, in addition to the riveting all round the plate?—B.

A TELEGRAM from Cairo, dated Jan. 10, states that the first through train reached Khartoum on that day.

IT has been noted in connection with the prevailing epidemic of influenza that in the North of England, where the disease is common amongst artisans, the men who work in very high temperatures alone appear to have escaped the infection.

ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, *332, Strand, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries, put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

*** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

The following are the initials, &c., of letters to hand up to Wednesday evening, Jan. 17, and unacknowledged elsewhere:—

R. W. M.—G. E. O.—A. Stacey.—An Old Reader.—Mechanic.—G. A. Haig.—F. L. H.—W. S.—W. M.—Seeker.—Meteor.—NormanLattey.—Jack of All Trades.—H.—A Fellow of the Royal Astronomical Society.—Monty.

B. M. S.—We have inserted your first query, though it is put so vaguely that we fear you will get but poor replies. The second can be answered by nobody who has not seen the premises you propose to light. To ask at one and the same time "what power dynamo you will want" and "what the candle-power of lamps would be," is a little confusing! You had really better get an estimate from a decent electrical light contractor.

L. B. B.—Thanks; but drawing is not capable of reproduction.

W. M.—Methods of demagnetising watches have been given many times. The simplest seems to be to spin the watch round in the field of a magnet. The terms "burnt out" are misleading. See p. 297, May 14, 1897, No. 1677, and the indices generally.

B. P. MEHTA, Rangoon.—Full instructions for making a phonograph were given some years ago, and were subsequently published in book form by E. and F. N. Spon, 125, Strand, W.C. The numbers are all out of print. As to the optical lantern, such numbers as are still in stock will be sent.

NO SIRRAH.—Any bookseller can supply a work giving the Morse code of signals. Cassell and Co., Ltd., publish "The Telegraph Guide," price 1s., and Lockwood and Son publish works giving the usual code, but obviously not the "code" employed for signalling during war operations. Culley's work was mentioned on p. 433, because it is the standard; but it was expressly mentioned that "any of the small handbooks on the telegraph give the alphabet."

REX.—The subject has been frequently referred to in back volumes, and the action of light on selenium is well known. See pp. 56, 212, 338, Vol. XXVII., and the *Proceedings* of the Royal Society.

J. R., Penrith.—We do not see our way to issue another set of "Best Books" just yet, at the same low price. For one thing, paper alone is twenty per cent. higher in price than it was two months ago. We have not many sets of the present series left, and if your friend wants a bargain he will secure one before they all go off. He will not have a chance like it again just yet, we fancy. We send the set of 25 Best Books and Bookcase, complete for 30s., free delivery in London, or packed for rail in substantial wooden case free of extra charge.

P. ERNEST OLD.—It is not easy to guess which coil you mean, as so many have been given. Probably it is that described and illustrated on p. 241, May 1, 1896, which is the nearest to the "early part of '96."

WALTER SCUTT.—Thanks for the cuttings.

W. M. WORSSELL.—Many thanks; but letter and sketch of mock sun seen by you at Arundel on Jan. 11 reach us too late for this week, and will be out of date or crowded out by next week. It is desirable to send us notes of this kind *at once*, so as to give us a chance of publishing with next issue.

W. E. NICOLL.—The same remarks must apply to your otherwise interesting note on the meteor seen on the 9th instant in daylight at Woolwich, which you think is probably the same as that referred to in letter 43195.

THE strength of the German navy this year will be 152 ships, comprising 17 battleships, 8 ironclads, 11 large cruisers, 27 small cruisers, 5 gunboats, 84 torpedo boats. In sixteen years' time it is stated that the navy will be increased to 222 vessels.

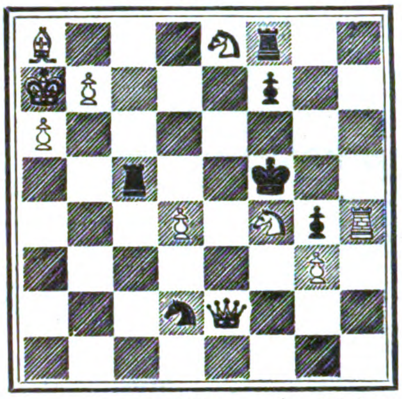
IN modern wind machines it is calculated that a 14ft. wheel will yield ¼H.P. with a 10-mile wind, ½H.P. with a 12-mile wind, 1H.P. with a 16-mile wind, and 2½H.P. with a 25-mile wind. A 20ft. wheel will give 1¼H.P. at 10 miles, increasing to 5½H.P. at 25 miles. A wheel 30ft. diameter is estimated to produce from 3H.P. at 10 miles to 9H.P. at 25 miles velocity; a 40ft. wheel ought to give from 5 to 12H.P.

CHESS.

All communications for this column to be addressed to The CHESS EDITOR, at the Office, 332, Strand.

PROBLEM No. 1710.—By T. TAVERNER.

Black. [6 pieces.



White. [10 pieces.

White to play and mate in two moves.

(*Solutions should reach us not later than Jan. 29, 1900.*)

Solution of PROBLEM No. 1708.—By G. B. VALLE.

Key-move, Kt-K B 5.

NOTICES TO CORRESPONDENTS.

PROBLEM No. 1708.—Correct solution has been received from A. Tupman, Whin-Hurst ("Appears ingenious, but not a very difficult one"), J. E. Gore ("Very pretty"), Rev. Dr. Quilter ("An admirable and clever problem"), Richard Inwards, F. B. (Oldham), Quizco, N. M. Munro, W. Masters, H. Hall, A. H. W. (reply sent by post).

H. B. F., TOM TIT, J. M. C., W-H.—Only solution as above.

SPECIAL OFFER.—CHEAP VOLUMES.

In the course of the next few months we are compelled, owing to the making of the new street from Holborn to the Strand by the London County Council, to remove our Offices and Printing Works. Due notice of our removal will be given shortly. In the mean time, to reduce stock and save trouble of removal, we offer readers desirous of making up sets of back volumes *any volume* in the list below at HALF PRICE, or post free for 4s. 1d.

Any reader desirous of making a free library or working men's club a present of a few sets of volumes will find this a favourable opportunity. The offer is only available till our removal.

TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

6s. 6d. for Six Months and 11s. for Twelve Months, post free to any part of the United Kingdom. For the United States, 13s., or 3dol. 25c. gold; to France or Belgium, 13s. or 16f. 50c.; to India, New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-Office Order. Back numbers can also be sent out by the ordinary newspaper post at the rate of 3d. each.

Vols. IV., V., VI., VII., XII., XIV., XXIV., XXX., XXXII., XXXVI., XXXIX., XL., XLII., XLIII., XLIV., XLV., XLVI., XLVIII., L., LI., LII., LIII., LIV., LV., LVI., LVII., LVIII., LIX., LX., LXI., LXII., LXIII., LXIV., LXV., LXVI., LXVII., and LXVIII., bound in cloth, 7s. each. Post free, 7s. 7d.

Indexes to Vol. LI., and to subsequent Vols., except Vols. LIII., LV., LVI., LVII., LIX., LXI., 3d. each, or post free 3½d. Cases for binding 1s. 6d. each.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each post free from the office (except index numbers, which are 3d. each, or post free 3½d.)

For Exchange.

The charge for Advertisements in this column is 6d. for the first 16 words, and 6d. every succeeding Eight, which must be prepaid.

SPECIAL NOTICE. — *Correspondents are strongly recommended not to send money or goods to strangers. The safest way when dealing with unknown advertisers is to send a Post Office Order made payable —— days after date, when in case of non-arrival of goods, or dissatisfaction, payment can be stopped.*

Telescope. Calver 8½in., finder, eight eyepieces. Wanted, good light Brass-finisher's Lathe.—BANKS, Corporation-street, Bolton.

Volt-Meter (Cruickshank's), 6v., nearly new, 15s. Exchange for Grindstone, Forge, Anvil.—CULLUM, 84, Askew-road, W.

In Exchange for 1s. 2d. you will receive the best Engineer's Pocket-Book published.—Read on.

The "Practical Engineer" Pocket-Book, price 1s. 2d., including postage, contains nearly 600 pages of engineering data.

In Exchange for 1s. 8d. you will receive the "Practical Engineer" Pocket-Book and Diary, leather gilt.

The "Practical Engineer" Pocket-Book AND DIARY, price 1s. 8d., bound in leather, gilt edges, elastic band.

The "Practical Engineer" Pocket-Book, 1s. and 1s. 6d., from all Booksellers, or 31, Whitworth-street, Manchester.

"English Mechanic," 1891 to 1899, perfect. Exchange for Horizontal or Vertical Model Steam Engine, if perfect. —JAMES GOWING, Souter Point Lighthouse, Marsden, South Shields.

Optical Lantern, mixed jets. "Injector" using house gas; also ordinary gauge, sell.—WILLIAMS, Bishop's House, Clifton.

"English Mechanics," 527 numbers, complete, up to date, cash exchange.—J. D., 21, Basuto-road, Fulham.

Wanted, **Screw-cutting Lathe** about 5½ by 5ft. Will exchange Gas-Engine, ¼ B.H.P., two flywheels, and Safety Bicycle, Dunlops.—Letters, 23, Martindale-road, Balham.

Exchange, **Electric Motor Castings,** unfinished Model Tramway, Accumulator. Offers invited.—MILNE, 24, Palace-road, Crouch End.

Exceptionally beautiful Model **L.N.W.R. Locomotive** AND TENDER; length, 5ft. 7in. Burns coal. Gauge, 6⅛in. Cost over £350. Sacrifice bargain. Offers part exchange.—Letters, O., 14, Raveley-street, Kentish Town.

Two Bicycles, lady's and gent.'s, value £20. Wanted, S.S.S. Lathe, 5⅛in., 6in.—S, Lumley-buildings, Pimlico, London.

Muller's **Alpha Gas-making Machine,** for 80 lights, in working order, £20, or exchange a good 5½ Screwcutting Foot Lathe and Tools.—SUTTON, Navigation, Whittle, Chorley.

"Mysteries of London. 1845," published 18s., two vols. in one, first series, over 100 illustrations, 840 pages, scarce.

Also **"Manby's Telescopic Companion,"** 21 plates, 17in. by 20in., published 25s. Exchange for good Field-glass, telescope, or offer.—DESMOND, 50, Woodchester-street, W.

Lathe, 4in. centre, equal to new, £5 or Exchange.—Offers to LEVER, 359, Lillie-road, Fulham.

For Sale.

The charge for Advertisements in this column is 6d. for the first 16 words, and 6d. every succeeding Eight, which must be prepaid.

New Illustrated Price List of Screws, Bolts, and NUTS for model work, drawn to actual size, sent on receipt of stamp. —MORRIS COHEN, 132, Kirkgate, Leeds.

Watch and Clock Tools and Materials. Catalogue, over 1,000 Illustrations, post free, 6d.—MORRIS COHEN, 132, Kirkgate, Leeds.

Wheel-cutting and Dividing in Brass or Iron to 12in. diameter.—CLEGG, Belinda-street, Hunslet, Leeds.

Amateur Astronomers.—"Hints on Refractors and Reflectors," by W. Thornthwaite, F.R.A.S., invaluable, 1s., post free 1s. 2d.—Below.

Handy Map of the Moon, by Mellor, F.R.A.S., 2s.; post free 2s. 6d.—HORNE and THORNTHWAITE, 416, Strand, London.

Lathes and Machined Parts, Wheels, Chucks, Fans, Angle-plates. Illustrated list, 2d.—JARRATT, Queen-street, Leicester.

Rubber Outer Covers, 3s. 6d. Prepared Canvas, 90 by 9, 1s. 3d.; rubber solution, best quality, 1lb. tins, 1s. 6d.—PEMBERTON.

Air Tubes, all sizes, best quality, 2s. 9d. each. Air tubes with Dunlop valves fixed, 3s. 9d.—PEMBERTON.

Cushion Tires, 3s., 4s., 5s. Solid Tires, 3s. All sizes stocked.—PEMBERTON.

Detachable Outer Covers (Licensed), 12s. 6d. each; all cycle accessories and cycle rubber goods stocked.—PEMBERTON and Co., 1, Cardwell-place, Blackburn.

"Acetylene: its Characteristics, Generation, AND USE," with Descriptive Catalogue of "Incanto" Apparatus; just published, 2d. post free.—THORN and HODDLE, 1 Tothill-street, Westminster, S.W.

Brass Casting Made Easy by using Wells' specially prepared Moulding Loam. Brass casting a pleasure.—Below.

Sold in 5lb. canisters, 2s. 3d.; 10lb., 3s. 9d.; 20lb. 6s carriage paid, with instructions.—Below.

Plumbago Crucibles, with instructions for melting brass, sixpence each post free.—GEO. WELLS, Needham Market, Suffolk.

Mail Cart Wheels and Perambulator Furniture.—WALKER BROS., Primo Wheel Works, Sheepscar, Leeds.

50,000 Choicest **Microscopical Objects.** New and Second-hand Microscopes, Cabinets, Mounting Materials.—SUTER, 10, Highweek-road, Tottenham.

Catapult Elastic. square, 2d., 4d., 6d., 9d. yard. Capapults, 6d., 9d. Postage 1d.—MOODY BELL, Cheltenham.

Superb 18½in. **Mirror, in Tube,** for photographing and observing, either Newtonian or compound form, focus 96in.—Below.

Fine 4½in. **Reflector,** as new. 3 powers, £3. 12½in. Equatorial "Hints," 1s. 1d.—G. CALVER, Widford, Chelmsford.

Books.—All out-of-print books speedily procured; any subject. State wants.—BAKER'S GREAT BOOKSHOP, Birmingham.

Rubber Outer Covers, average 16oz., Para rubber 6s. each.—FRANKLANDS.

Rubber Outer Covers, 8s. 6d. each, 86s. per dozen. —FRANKLANDS.

Cushion Tires, 3s., 4s., 5s. Solid Tires, 2s. 6d., 3s. All sizes stocked.—FRANKLANDS.

Air Tubes, best quality rubber, 2s. 9d. each. Fitted with Dunlop valve, 3s. 9d.—FRANKLANDS.

Air Tube, Para rubber. Marvellous value. Large stock to clear. Perfectly air-tight., 2s. each.; 21s. per dozen.—FRANKLANDS.

Cycle Capes, 3s. 6d., 4s. 6d., 5s. 6d. Also a few cycle Capes, guaranteed waterproof, 3s. 6d. each.—FRANKLANDS.

Detachable Outer Covers, licensed, 12s. 6d. each. —FRANKLANDS.

Saddles.—A clearing line in ladies' and gents' saddles, 3s. 6d. each, 24s. per dozen.—FRANKLANDS.

Inflators, 18in., 1s. 6d. each, 15s. dozen.—FRANKLANDS.

Bells.—Special line, double gong, usual price, 12s. dozen, will clear 6s. per dozen.—FRANKLANDS.

Prepared Canvas, 90 by 9, 1s. 3d. each, 12s. per dozen.—FRANKLANDS.

Pedal Rubbers, 6d. per set of four, 4s. 6d. per dozen sets; no rubbish.—FRANKLANDS.

Spanners, nickel, usual price, 18s. per dozen. Will clear a few dozen at 7s. 6d. per dozen.—FRANKLANDS.

Cycle Accessories and Cycle Rubber Goods. We hold the largest stock in the North.—FRANKLANDS, Astley Gate Blackburn.

Castings in Steel or Malleable Iron made from your own patterns.—DRONFIELD CASTINGS COMPANY, near Sheffield.

Telescope, 8½in. Calver, splendid instrument, eight eyepieces, Barlow lens, alt-azimuth mounting, £20.—BANKS, Bolton.

Telescope Mirror, silver-on-glass, 7in. dia., good figure, three eyepieces.—BANKS, 18, Corporation-street, Bolton.

Banks' Patent Focimeter, the only accurate lens analyser and axis indicator, 60s.—BANKS, Bolton.

Banks' Portable Optician's Trial Case, with spherical and cylindrical lenses, nothing better, from 35s.—BANKS, Bolton.

Bargain.—Magnificent model **Vertical Engine,** tubular boiler, glass gauge, whistle, double-action slide-valve cylinder; bronze stand. Exhibition model, silver-plated, high speed, and guaranteed perfect; worth 42s., accept 12s. 6d. free. Photograph 1d. —MANAGER, Hassall's Chemical Works, Stratford, E.

Edison Phonograph, automatic motor. grand instrument, only £2; bargain.—ANDREW RALEIGH, 12, Newstone-buildings, Holborn, W.C.

Cinematograph, Camera, Projector, and Printer. Will take single snapshots. Cost of film for 700 pictures, 3s. 6d. Handsome and highly-finished. Only £6, complete with instructions. —ANDREW RALEIGH, 12, Newstone buildings, Holborn, W.C.

"Demon" Gas-Engines, Otto principle, are high-class engines, embodying all modern improvements at popular prices.

"Demon" Gas-Engines, awarded Prize Medal for efficiency, have a world-wide reputation for absolute reliability.

"Demon" Gas-Engines are the result of many years' experience devoted entirely their manufacture.

"Demon" Gas-Engines, made all sizes from ½B.H.P. upwards at popular prices. Particulars free on application.

"Demon" Oil-Engines are the acme of simplicity, and give universal satisfaction, from ½B.H.P. to 10B.H P.

"Demon" Portable Oil-Engines, 6B.H.P., 7½B.H.P., 10B.H P., for Farmers and Colonials.—PASLEY and COMPANY, Sherborne, Dorset.

Armstrongs' Pocket Accumulators. Hand Lamps, Photographic, Cycle, and Reading Lamps, Scarfpin Sets, Dynamos, Motors.—ARMSTRONGS.

Armstrongs for thorough good Accumulators. Send to us when requiring something good at ridiculously low prices.

Armstrongs are Makers of over 600 sizes in Pocket and Portable Accumulators. Fully illustrated catologue, 4d.

Armstrongs' "Searchlight" Cycle and READING LAMPS used in preference to all others. See illustrations in catalogue.

Armstrongs for practically mounted Scarfpins, Ammeters, Voltmeters, Galvanometers, Motors, Charging Dynamos, and Accumulator Charging Batteries.

Armstrongs advise you to get their Catalogues, testimonials, &c., when requiring above goods.—ARMSTRONG and Co., Twickenham, London.

Astronomical Telescope, 5in. Dollond equatorial, finder, eyepieces, £45 10s.—HUGHES, Brewster House, 82, Mortimer-road, Kingsland, N.

Astronomical Telescopes. Fine 6in., £32 10s.; 4in. ditto., £19 10s.; 5½in. Reflector, equatorial, £11 10s. Bargains.—HUGHES.

Astronomical Telescope. Magnificent Gregorian reflector, 4½in., beautifully mounted by Martin, cost £80, price £12 12s.—HUGHES.

Astronomical Telescopes. Fine 4¼ Lancaster, splendidly mounted, £36 10s.; with double 3¾ Dolland eyepieces, £13 13s., cost £35.—HUGHES.

Magnificent Triple Lantern, cost over £30, price £14 14s by Perkins and Rayment, three sets of lenses, jets.—HUGHES.

Triplex Experimental Lantern, by Ladd, cost £100, price £21 10s. Binocular Microscopes, Bargains; Objectives Powell and Lealand.

Rontgen Rays X Coil, 10in. spark, cost £65; also another 8in. spark, bargains.—HUGHES.

Model Boiler, 13in. tubular, nearly new, tested 50lb., brass mountings, 17s.—51, Winchester-road, Romsey.

Gas-Engine. ½HP., new, horizontal Otto Cycle, £4 10s.—H. PESTELL, Gower-road, Hayward's Heath, Sussex.

Launch and other Steam-Engines, Boilers, Lathes, Propellers, and all kinds of machinery.—S. SMITH.

Lathe, 5in. back gear, 5in. single, and 3½in. single, complete.—S. SMITH.

Propellers, improved pattern, from 12in. to 33in., shafts, &c.—S. SMITH, 3, West-street, Soho, W.C.

Miscellaneous Electrical Apparatus.—Bells, Telephones, Relay, Morse Keys, Wire, &c.—G. BURROWES, Maids Moreton, Buckingham.

The Britannia Co. publish monthly a Register of Gas, Steam, Hot Air, and Petroleum Engines.

Above List contains details of nearly 3,100 lots Lathes, Planers, Shapers, Drilling Machines and other tools.

Also Pumps, Lifts, Steam and Petroleum Launches, and various machinery and plant. State details of requirements.

Send 2d. Stamps for specimen copy—BRITANNIA WORKS, Colchester, or call at 100, Houndsditch, London.

Stamped Steel Boats, various sizes, with air-tight compartments, very light and handy.

When sending, send precise details, and we will quote for items not yet in our list.

Call Britannia Co., 100, Houndsditch, London. All letters to BRITANNIA WORKS, Colchester.

Above items are many of them second-hand, and offered at low prices.

Cycles to Order. Up-to-date and guaranteed twelve months. Gents.', £5; Ladies', £5 10s. B.S.A. Cycles, £8. Easy payments arranged. Repairs cheap and promptly returned—HASSELL, 45, Stuart-road, Liverpool.

Genuine **Edison Phonograph,** in new and perfect condition. Will sell for 55s., including records, &c. Cost much more.—HASSELL, 45, Stuart-road, Liverpool.

Compound Slide-rest Castings, modern design, Whitworth pattern, 6in., 11s.; planed, 34s; 4½in., 7s. 6d.; planed, 26s.—MARTIN.

Compound Slide-rest Castings, 4in., 6s. 6d.; 3½in., 5s.; 3in., 4s. Castings in stock ready for immediate delivery.

Back-gear Lathe Head Castings, 3in., 6s. 6d.; 3½in., 8s. 6d.; 4in., 10s. 6d.; 4½in., 16s.; 5in, 20s.

Change Wheel Castings, 14-pitch, 13s.; 12-pitch, 16s.; parcel of 22 wheels, in stock.

Planer, Lathe, Shaper, Drilling Machine CASTINGS. Catalogue five stamps. Largest and best stock in London.

W. Martin and Co, East-road, West Ham, E.

Boron Battery Electrical Supply Co., Chemical and Electrical Experts, 18 Albion-street, Everton, Liverpool. Established 1874.

Boron Battery is the best, and most powerful primary cell, certain in action, free from polarisation.

Boron Cells, 3 in series, will charge 12 cycle set accumulators at once, costing only 2d.

Boron Cells effectually replace dynamos, engines, or motors. Cheapest chemicals, non-corrosive or fuming, easily obtained.

Boron Cells charge accumulators without straining the plates. Eight cells charge 100v. accumulators in three hours.

Boron Cells for X-rays, motors, lighting, plating, special cells for each, direct or indirect currents.

Boron Cells sold since last year have now amounted to over 40,000, and perfect satisfaction obtained.

Boron Cell representatives and agents required. Liberal terms to the trade. Non-practical people save stamps.

Boron Cells.—Testimonials from all parts of the world. Inspection cordially invited. The greatest electrical triumph.

Boron Cell.—Price lists, containing latest improvements, 2½d. stamps. Visits arranged by appointment.

Portable **Equatorial Stand,** gunmetal circles, levels, &c., cost £15.—F. H., 22, King-street, Grimsby.

The English Mechanic
AND WORLD OF SCIENCE AND ART.
FRIDAY, JANUARY 26, 1900.

A SMALL MOTOR-CAR, AND HOW TO BUILD IT.—IV.

HAVING the cylinder finished, we will next consider the cylinder cover, Fig. 10. This also is of cast iron, and its pattern will be the same as its casting, with the addition of shrinkage. Machining is also to be allowed for where it fits on to the cylinder end, on the edge, and on each of the 1in. bosses for the nuts holding it in place. The six ribs not only add very greatly to the strength, but also help to keep it cool. The six $^7/_{16}$in. holes for the studs are best drilled from the solid. To turn this casting I should grip it by the edge in a jaw-chuck and face the part which goes next to the cylinder. There is no need to face right over the projecting part marked 4in. diameter. Having faced one side, reverse it in the chuck, gripping it by the $^3/_{16}$in. rim and using the back centre to steady it. The edge can now be turned and a cut taken over the tops of the six small bosses, which will insure their being all of the same height and true with the cylinder joint. A circle $5^3/_{16}$in. diameter is next to be lightly scribed, on which to pitch out the centres of the $^7/_{16}$in. stud-holes. When these are drilled, the cover can be placed in position on the end of the cylinder, and the holes marked off for the studs. These should next be drilled and tapped, and studs screwed tightly in, as shown in Fig. 9. Fig. 11 is a vertical section of the valve-box on the line A B of Fig. 12, which is an end view showing the facing for the inlet valve. Fig. 13 is a horizontal section on the line C D of Fig. 12. The box is to be cast in iron, and should be of the same metal from which the cylinder is cast, so that the expansion and contraction may be the same for each.

This may be considered a theoretical detail; but it is by attention to very small matters that the best results are obtained. The pattern and core-box work on this part of the engine requires to be done with care; otherwise we shall have the cores showing through where not desired, or the metal left too thin to be of use. The pattern will be made solid, and a print put on the side which goes next to the cylinder. This print will include the print for the water-jacket, and also for the port leading to the valves. The shape of the print will be rectangular, with semicircular recesses taken out at each corner. Two core-boxes will be necessary —one for the water-jacket, the other for the valve-box and exhaust-branch. The guide for the exhaust-valve stem is to be cast solid and drilled out afterwards, as are also the four holes for the studs which hold the valve-box to the cylinder. In Fig. 11 will be seen a dotted line, A; this indicates the shape of the facing which corresponds with and goes against that on the side of the cylinder (Fig. 4). At D (Fig. 12) is the boss for the ignition-plug, seen also in section in Fig. 13. It is to be cast solid and drilled out. The shape of the facing on to which the oval flange of the exhaust-pipe goes is seen dotted in Fig. 13, the depth of the tapped holes for the studs showing in Fig. 11. In this figure the tapped holes for the inlet-valve cover-studs show also.

The first part to machine will be the flat face which goes next the cylinder. The casting must be lined out first, of course, and care taken to insure the centre line of the exhaust-valve guide and seating, and the centre of the hole for inlet-valve seating being at the correct distance ($1\frac{1}{4}$in.) from the cylinder-joint face. Having this face planed, the casting should be secured to an angle-bracket on the face-plate of the lathe, with the facing for the inlet-valve seating outwards. To reduce overhang, the exhaust-valve stem-guide may project into the lathe mandrel into the coned hole made for the centre. The oval facing can now be faced off, and the hole for inlet valve-seating bored out $1\frac{3}{8}$in. diameter. At the same setting the exhaust-valve seat can be machined, the actual seating being coned out at 45° to the bore, and made a bare $^1/_{16}$in. wide. Every precaution should be taken in drilling the $\frac{3}{8}$in. hole for the exhaust-valve stem. It

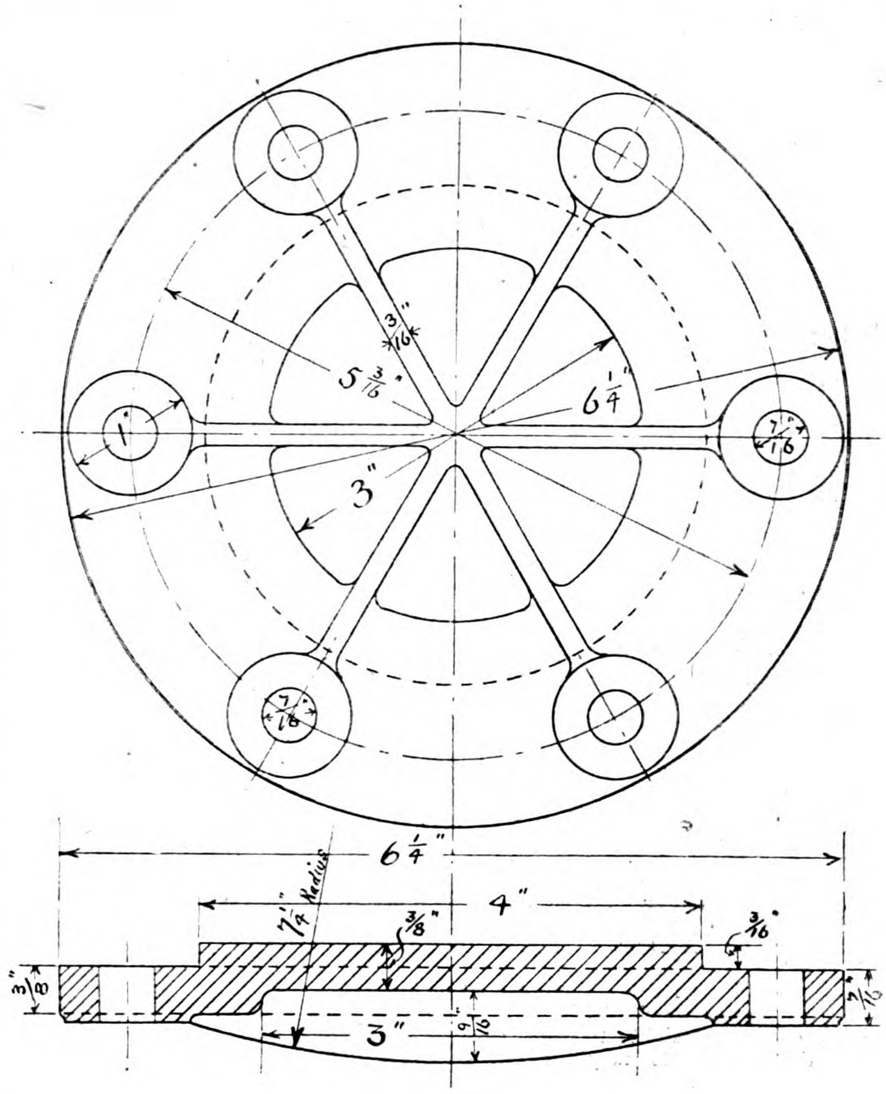


FIG. 10.

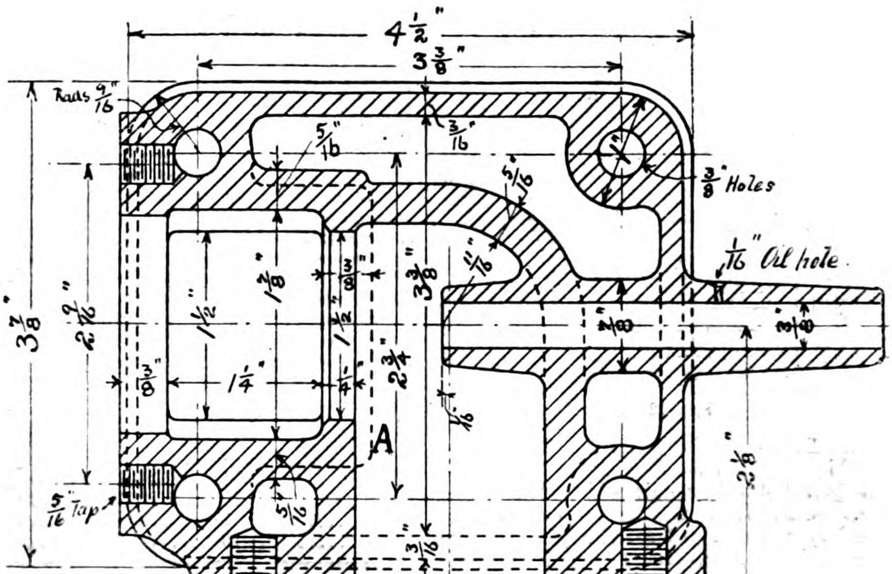

FIG. 11.

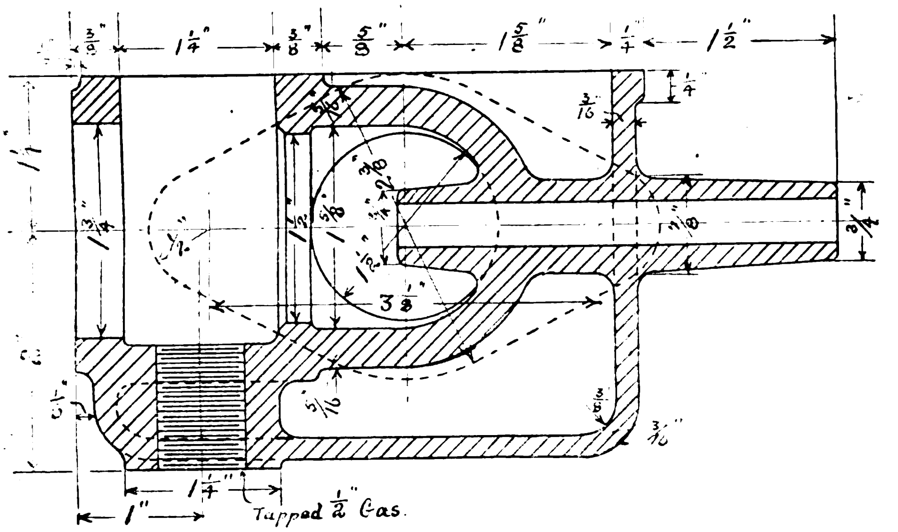

FIG. 13.

must be truly concentric with the valve-seat. The way I should adopt would be to run a ⅛in. or ¼in. twist-drill through first as truly as possible, feeding the drill up to its work by the back centre of lathe. Having drilled the hole clear through, take a straight piece of iron, steel, or brass rod, which is a fit in the hole drilled, push it through the hole, when, if the face-plate be rotated, the projecting end of the rod will indicate if the hole is true or not. If really true, the hole may be finished with a ⅝in. twist-drill. If, however, the hole runs out, other means must be adopted. With a small boring-tool bore up the hole to ⅝in. diameter for about ½in. or ⅝in. deep. A Dee bit will now be required with which to bore the hole through; the part bored up insures the Dee bit starting true, after which it will continue to cut its way straight through, even though the small hole may be out of

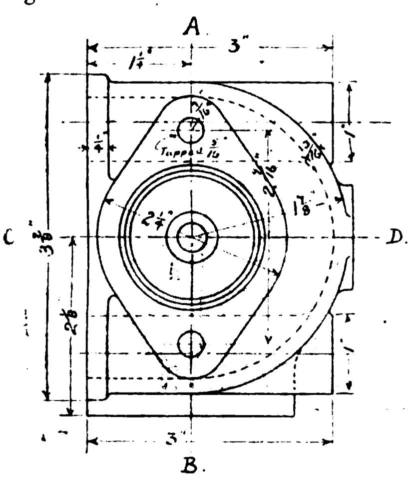

FIG. 12.

truth. To secure the casting to the angle-plate it would be as well to drill the four ⅜in. holes (through which the studs pass, which hold the valve-box to the cylinder) next in order after planing the cylinder-joint face. Bolts passed through these holes and the angle-plate will hold all secure during the facing and boring operations. The tops of the bosses on which the ⅜in. nuts bear are to be faced off with an arbor cutter. The holes in the valve-box facing on the cylinder can now be marked off, drilled and tapped, using the valve-box itself as a template. See that the studs are really tightly screwed into the cylinder. Dimensions can be obtained from Fig. 8. The studs for the exhaust branch facing should stand up 1in. above the facing, and those for the inlet-valve seating should project ¾in. from the surface of the facing.

Note that a 1/16in. oil-hole, countersunk, is to be drilled in the guide of the exhaust-valve stem, where mentioned in Fig. 11. The bosses for the four ⅜in. studs run right through the casting, as shown in Fig. 12. When the casting has been bored and turned, remove it from the lathe, and plane over the facing for the exhaust-pipe flange. Drill the boss for the ignition plug, and face it off with an arbor cutter, after which it may be tapped ¼in. gas thread.

ASTRONOMICAL NOTES FOR FEBRUARY, 1900.

The Sun.

Day of Month.	Souths.	At Greenwich Mean Noon. Right Ascension.	Declination. South.	Sidereal Time.

The method of finding the Sidereal Time at Local Mean Noon at any other station is explained on p. 438.

Having arrived at a period of Sunspot Minimum, we can hardly expect the Great Centre of our System to exhibit much, if any, superficial detail of interest to the ordinary observer; still the Sun may be examined from time to time as occasion offers.

During, and especially towards the end of the month, the Zodiacal Light may be looked for after sunset in the West.

Sextans	14	11 p.m.
Leo	15	10 p.m.
Virgo	17	2 a.m.
Libra	20	Noon.
Scorpio	22	9 a.m.
Ophiuchus	22	10 p.m.
Sagittarius	24	10 a.m.
Capricornus	26	6 p.m.
Aquarius	27	9 a.m.

Mercury

is a Morning Star at the beginning of February, but comes into superior conjunction with the Sun at 9 p.m. on the 9th, after which, of course, he sets after the sun. He is somewhat indifferently placed for the observer, though his position improves towards the end of the month, and he will be easily observable in the succeeding one. His angular diameter increases from 4·8″ early in February to 6·0″ by the 28th.

Day of Month.	Right Ascension.	Declination South.	Souths.
	h. m.	° ′	h. m.
1	20 36 6	20 39·8	11 51·7 a.m.
6	21 18·6	17 52·3	0 6·9 p.m.
11	21 46·6	15 30·9	0 22·2 ,,
16	22 21·5	12 1·7	0 37·3 ,,
21	22 55·9	8 1·3	0 51·9 ,,
26	23 28·4	3 41·9	1 4·7 ,,

Starting thus in Sagittarius, Mercury will cross Capricornus and Aquarius, and be found at the end of the month in the confines of the last-named constellation and Pisces. He travels through a region of the sky curiously destitute of any but small stars.

Venus

is an evening star throughout the month, and is becoming a brilliant and conspicuous object in the West after sunset. Her now perceptibly gibbous disc subtends an angle of 12·9″ at the beginning of February, increasing to one of 14·6″ by the end of the month.

Day of Month.	Right Ascension.	Declination.	Souths.
	h. m.	° ′	h. m.
1	23 8·2	6 55·3 S.	2 22·9 p.m.
6	23 30·5	4 21·6 ,,	2 25·5 ,,
11	23 52·5	1 45·2 ,,	2 27·8 ,,
16	0 14·4	0 52·4 N.	2 29·9 ,,
21	0 36 1	3 29·7 ,,	2 31·9 ,,
26	0 57·8	6 5·2 ,,	2 33 8 ,,

It will be seen from the above ephemeris that Venus will travel from a point where Aquarius and Pisces are conterminous over the greater part of the last-named constellation. As in the case of Mercury, her path is quite void of any conspicuous stars.

Mars

is invisible.

† Near approaches. ‡ Moon has set. * Moon setting. A description of the above table will be found on pp. 438 and 439.

Jupiter

does not rise until between 3h. and 4h. a.m. at the beginning of February, nor until 2h. a.m. or so, at the end of it, and

Saturn and Uranus

are in a worse position still; but

Neptune

continues visible during practically the whole of the ordinary amateur's observing night, and his considerable height at transit places him in a most favourable position for observation.

And on other occasions when daylight will render the phenomenon invisible.

THROUGH A SMALL TELESCOPE.—VI.

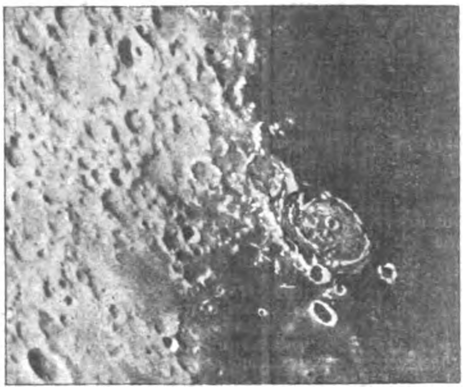
By NORMAN LATTEY.

METEOROLOGICAL conditions having been somewhat more favourable than during the previous week, the moon will occupy our entire attention in this paper. A reference to Fig. 1, giving a fine view of the "terminator" at first quarter—i.e., when daylight has advanced exactly half-way across the lunar disc—and Fig. 2 the key map thereto, will enable the student to easily locate all the features which we are about to deal with.

Turning our telescope on to the upper or southern portion of the illuminated area, one of the principal depressions we notice in this much pitted region is Maurolycus, ranking among the grandest walled plains on the moon. It extends fully 150 miles from east to west, and even more from north to south, covering an area equal to about that of Switzerland. This vast inclosure really consists of several crater rings crowded together and encroaching on each other; the whole bounded by a massive and deeply-terraced irregular wall towering nearly 14,000ft. above the interior. The central mountain is of great altitude; its lofty summit catching the rays of the rising sun long before the rugged peaks of the elevated ramparts begin to be illuminated.

Hard by on the right is a similar and even more extensive formation, Stofler, a magnificent spectacle when the morning terminator lies rather east of the western wall. Its surrounding rim is very uneven, varying from 3,000 to 12,000ft. in height. There are several conspicuous craters on the east and south walls. The floor is smooth and steely-grey; altogether, it well repays half an hour's careful study.

Immediately below Stofler lie two almost similar ring-plains, Aliacensis and Werner, 53 and 45 miles in diameter respectively. Both are surrounded by terraced borders of tremendous height—among the loftiest on the moon. On the eastern wall of Aliacensis the peaks rise to over 16,000ft., and around Werner they are hardly inferior. The latter contains a splendid central mountain 4,500ft. high, and at the foot of the north-east wall lies a bright little area suspected to be a comparatively new feature, possibly of recent deposits. To the north-west of this pair stretches a chain of dusky ring-mountains, Apianus, Playfair, Azophi, Abenezra, Geber, and Almanon. The last named is an interesting object about 36 miles across, surrounded by an irregular border of polygonal shape perforated on the south by a deep crater. Below and slightly to the east stands its more massive and rugged companion Abulfeda, some 40 miles in diameter. The encircling wall is much broken by narrow transverse valleys but finely terraced on the east and west. On the south-east originates the curious string of craterlets running in a straight line to the north-west wall of Almanon—a pretty sight under a low sun. Tacitus, still further to the west, has a lofty wall 11,000ft. above the floor

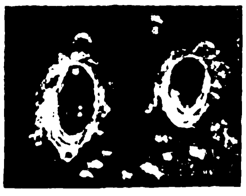


Sunrise on Posidonius.

and a conspicuous crater on the south-west rampart.

In Albategnius, one of the most prominent features near the terminator at this phase, we have a superb walled plain surrounded by a massive complex border rich in terraces, depressions, and winding clefts. The ridges are surmounted by lofty crests, one of which on the north-east, rears itself up to a height of 15,000ft. On the eastern side intrudes a fine circular crater Albategnius A, its towering peaks rivalling those of the larger formation. The central mountain of Albategnius exceeds 4,000ft., and is almost the only elevation on the crater-studded floor.

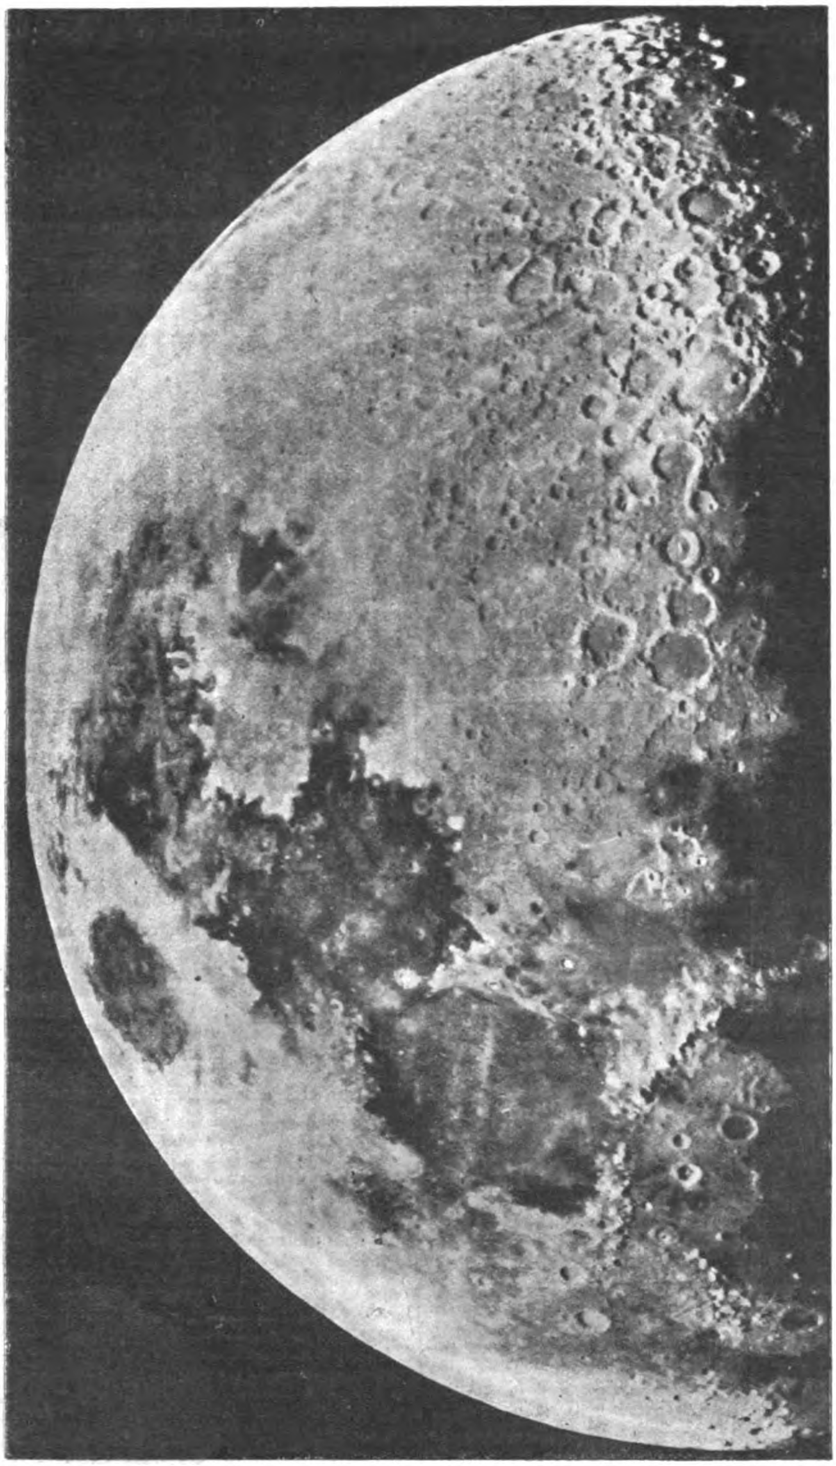
Immediately beneath Albategnius lies the ruined inclosure Hipparchus, an extensive ring-plain, whose broken walls bear unmistakable signs of physical decay. Its imperfect outline marked by the two deep craters Halley and Horrocks, can be barely detected in the photograph, but shows up in better relief under more oblique illumination. The interior of Hipparchus is crossed by many ridges and valleys, and near



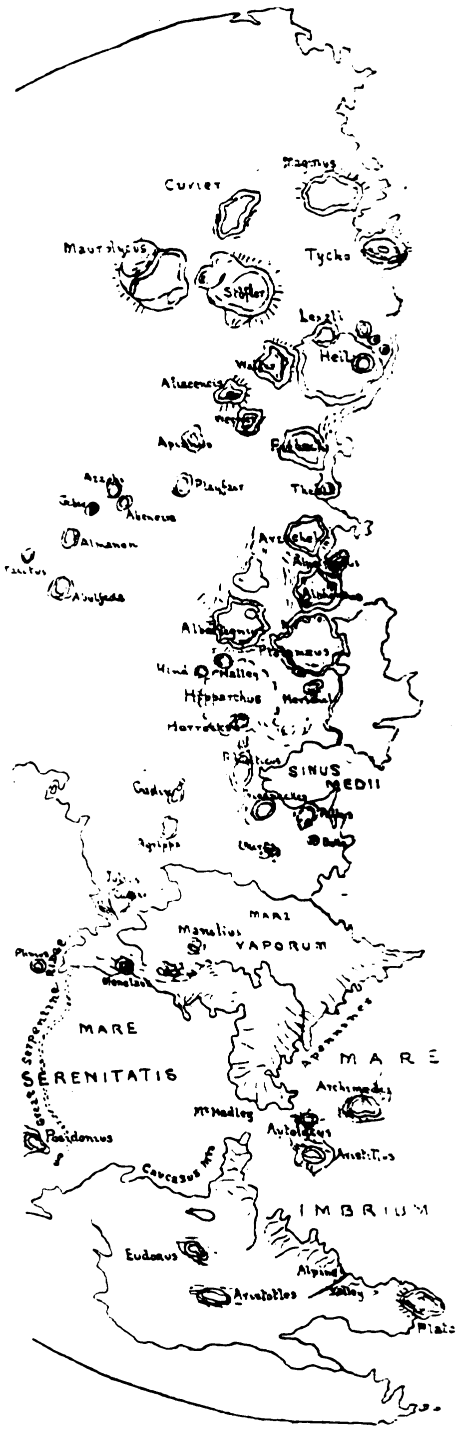
Eudoxus and Aristoteles. (Moon's Age, 6 l. 6h.)

the centre can be discerned the remains of what was evidently once a well defined ring. This region is specially interesting, and affords a pretty study under a low sun.

Crossing the head of the Sinus Medii, we soon reach Triesnecker, the centre of one of the most remarkable rill-systems on the moon. Although only fourteen miles in diameter, this famous object affords almost unlimited scope for examination under various phases. The north-west section of the wall is considerably higher than the rest, and exhibits many spurs and buttresses on the outside, with elaborate terracings within. The rill system—which needs a good night and high power to see really well in all its intricacies—consists of a complicated lacing of dark and light streaks which appear to grow wider and deeper as they approach higher ground. For this reason, the cause of which remains unexplained, they have been likened to an "inverted river system." To the westward are the twin formations Godin and Agrippa. Both have lofty borders deeply terraced. Still further in this direc-



Photograph of the Moon at First Quarter, as seen through a 3in. Telescope.



Key Map to Objects near the Lunar Terminator at First Quarter.

-tion, but some distance north on the promontory dividing the Mare Vaporum from the Mare Tranquillitatis lies the great irregular formation Julius Cæsar, remarkable for the duskiness of its vast floor, especially at the northern end. On its western flanks will be noticed a number of narrow valleys and low banks, besides three large swellings on the uneven interior.

Along the narrow southern "shores" of the Mare Serenitatis will be found three important objects all in a row: Manilius, Menelaus, and Plinius, the centre one, Menelaus, being almost immediately beneath Julius Cæsar. In Manilius we have one of the most brilliant objects on the moon, though only 25 miles in diameter. To the east will be noticed a small isolated mountain standing alone on the plains of the Mare Vaporum. Menelaus almost as conspicuous as Manilius, though slightly smaller, has a brilliant central hill, and is completely traversed by the bright streak crossing the Mare Serenitatis from north to south. The secret of these bright streaks, their nature, origin, and connection with the formations with which they seem to be associated, remains one of the yet inexplicable mysteries of the strange globe on which they occur. Plinius, the most westerly of the trio, to use the words of the late Gwyn Elger, "reminds one at sunrise of a great fortress or redoubt erected to command the passage between the Mare Tranquillitatis and the Mare Serenitatis." This magnificent circumvallation, somewhat triangular in shape, boasts exceedingly massive ramparts sloping much on the outside and incised deeply by wide and tortuous valleys. The interior is considerably brighter than the surrounding Mare, and several little craters occur on the summits and slopes of the walls. Here again we meet with an elaborate and delicate rill system seen tolerably well with a good 3in., and even better with a 4in.

Following the course of the western coast line of the Mare Serenitatis until we skirt the northern "shores," we eventually meet Posidonius, admittedly the finest telescopic object in the first quadrant. The figure gives a view of it under a low sun between five and six days after new moon. Its massive ring—within which, on the south-western quarter, can be seen the remains of a second concentric ridge—is about 62 miles in diameter, but not of specially high altitude. The most conspicuous object on the floor is the well-defined bright crater visible slightly to the east of the middle. The western wall is broad and regular, and perforated by several bright crater-rings. The floor, which shines with a silvery lustre, is scattered with craterlets, and scored by clefts and rill-valleys. A day or so later the Great Serpentine Ridge starts out of the darkness on the east, and extends for nearly 200 miles towards Plinius, like some colossal serpent wriggling across the smooth stretches of the *mare*.

Space now compels me to conclude with the two well-defined crater cups situated near the northern pole, Eudoxus and Aristoteles. Under a power of 200, when the moon was 6 days 6 hours old, this pair defied all attempts to adequately portray their rugged and lofty borders beautifully terraced within, and supported by complex buttresses and spurs without. Eudoxus, the smaller of the twain, is some 40 miles in diameter, with a border much broken by passes and clefts, particularly on its eastern wall, which contains two very deep fissures. Aristoteles, the companion to Eudoxus, is nearly half as large again, but similar in construction. Its ramparts are exceedingly lofty, one peak at the western end (stand-

ing out as a brilliant spec of light in the figure), rises 11,000ft. above the shadow-steeped floor. On the crest of the eastern wall stands a little crater, with its interior still unlit. The whole of the surrounding country is covered with a multitude of hillocks and craterlets, every eminence and depression standing out with stereoscopic sharpness and relief. No words can convey an adequate idea of the weird beauty of the scene as it appeared through the writer's 4in. Cooke refractor, even when stopped down to 3in. aperture.

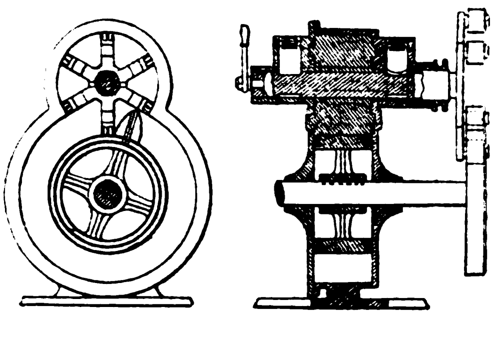
Next week we shall investigate the principal and most interesting features which at this phase lie on the edge of the terminator, some of them as yet hardly revealed in all their completeness. Copies of photographs, with much of the finer detail filled in at the telescope, will be again reproduced. But even these, striking as they are, will give the student but a poor idea of what his 2½in. or 3in., however indifferent, will show him.

DREAMS.

THERE are those who declare that they never dream at all; but in order to understand what they mean by this, it is necessary to understand what dreaming itself actually means, says H. G. Hutchinson, in *Longman's Magazine*. Dreaming does not merely mean, in the current sense of the term, that the mind is carrying on some kind of operations during sleep, but also that on awaking it should retain a consciousness of what it was thinking about during sleep. And in this regard it is to be observed, that when we are suddenly awakened it always seems to most of us as if we had been awakened out of a dream that is exceedingly vivid for the immediate moment. It is one of the most notable features of dreams that they vanish very quickly from our recollections a few minutes after we have thus been awakened, and we strive in vain to regain our grasp of what our mind had been doing while we were asleep. On the other hand, if the awakening has been gradual, it is probable that, in the leisurely process of the mind's reviving interest to the things of waking life, it unconsciously loses its grasp of what it had been doing in the sleeping state. From this it would seem likely that those who declare that they never dream do not really differ from the great majority of us who are dreamers by any difference of the operations of the mind while they are asleep, but rather that they are either slow in awaking, so that the mind loses remembrance of what it had been doing while they slept, or else that they lose their remembrance more quickly than most, owing to some difference of mental constitution. It would perhaps be curious to observe whether those who say they do not dream have any special characteristics in common, which would serve to explain this. The entire subject thus raised of the mind's remembrance of its experiences is a curious and interesting one. The common case of temporarily forgetting a name, which we painfully search for in vain, until it suddenly flashes across us while we are thinking of something quite different, is familiar enough, and yet more singular is the ultimate success in recalling a melody, of which all or part has escaped us and evaded us for a long while. It all goes to show that the mind has stored up within it, recollections of various kinds which the will is not always potent enough to summon into consciousness, but which something (probably some, often unsuspected, association of ideas) accidentally recalls. . . . It is essential, however, to realise that dreams have, properly speaking, no being unless they can be remembered when we awake. Without this a dream cannot be said to have occurred in any sense that is humanly speaking intelligible, any more than there can be deemed to be any continuity of the ego, or of the individual existence, except on the assumption that in the future life we are to have remembrance of our being in this.

ROTARY ENGINE.

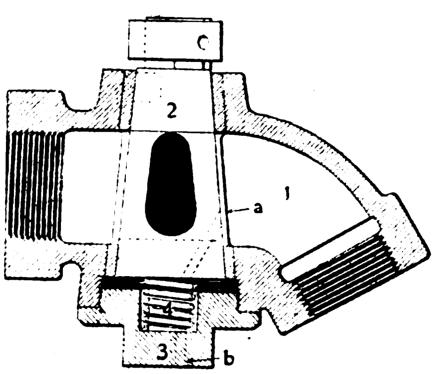
THE rotary engine shown in the annexed engravings differs from the usual designs in that it has an annular steam-space, and a central shaft on which is mounted a radial piston. The valve consists of a sleeve provided with ports, and free to rotate on a stationary shaft in which the admission and exhaust passages are formed. On the main shaft is a drum fitting steam-tight against the ends of the cylinder, and carrying the piston which fits steam-tight against the sides thereof. The fixed shaft and sleeve are contained in a cylindrical valve chest parallel to, and communicating with, the engine cylinder; and the sleeve is furnished with a number of radial partitions fitting steam-tight in the valve-chest, and one of them against the drum on the main shaft, six such partitions being shown on the drawings. Ports are formed in the sleeve



between each pair of partitions; and the fixed valve shaft has in it one admission and two exhaust passages in the form of tapering slots, the latter passages being on either side of the former. The piston gears with the partitions and rotates the valve, one side of it being thus opened to steam, and the other to exhaust. By a partial revolution to the valve-shaft (one-sixth revolution in the example shown), the position of steam and exhaust passages with respect to the piston may be interchanged, and the direction of rotation reversed. A cam device, by means of which the valve may be rotated continuously, instead of intermittently, is shown and described.

A SAFETY ANGLE-COCK.

SOME years ago, writes C. B. Conger, the angle-cock had a small hole drilled through the side, and also into the cavity inside the plug, so that when the angle-cock was shut, the air in the hose would bleed out through this hole, and allow the hose to



be easily uncoupled. In addition to this feature, it also acted as a safety feature; for this opening would let the air out of the hose fast enough to set the brakes on the train in case an angle-cock towards the engine was closed. If the other one, next the rear end of train, was closed, the leak would be enough to call the engineer's attention. But these cocks with the bleed-holes drilled in them soon began to leak so badly that the practice of drilling them was abandoned.

About two years ago, on the Illinois Central Railroad, they made a trial of drilling a ⅛in. hole obliquely down through the plug 2, to let the air from the hose down into the angle-cock cap or spring-box 3, when the cock was closed, another hole being drilled through the cap 3, as shown in the annexed cut, to let the air outdoors.

This plan has proved a success with a two years' trial; none of them leaking through this opening when the cock is open, as was the case when the bleed-hole was in the side of both plug and body of cock. They are used on engines and tenders only, and are not used on freight-cars. They are not patented, and can be used by anyone who wishes to do so.

The annexed cut shows the hole in the plug at *a*, and in the cap at *b*, connecting the hose with the atmosphere when the cock is closed.—*Locomotive Engineering*, N.Y.

ABOUT RIFLES: AND THEIR USES.

THE present war is an object-lesson in the use and effectiveness of the modern small-bore, smokeless powder, magazine rifle. It is, in fact, the first serious war in which white men have been opposed to one another, using this powerful weapon. . . . In war, where men can (theoretically, at all events) be killed every two seconds by one unseen rifleman further off sometimes than they can hear the report of this smokeless, death-dealing triumph of murderous modern gun-making science, it is obvious that marksmanship has not only a far higher scope for its skill, but, artillery and cavalry notwithstanding, there are circumstances where skilled individual rifle-shots are now of enormous practical value, out of all proportion to their other military qualities and to their numbers. This importance must, of course, vary a good deal with circumstances. In volley-firing, for example, preceding the final assault of a position, probably at several acres of enemy or trenches, fine shooting may not be so important. Possibly all that may be required in this sort of work is that the rifle should be fired at rapid intervals more or less in the required direction at elevations given by word of command. The other military qualities of courage, discipline, and determination then became relatively more valuable, and so on till the final bayonet charge carries the day. On the other hand, the entrenched rifleman repelling scattered troops in the open, the member of a surprise party waylaying an enemy's reconnaissance, the defender or "sniper" of an isolated post, is valuable exactly in proportion to his individual powers of marksmanship, every other military quality sinking comparatively into insignificance. . . .

As regards our regular Army, there is good reason to believe that until comparatively recently the opportunities given and time devoted to rifle practice were altogether inadequate. In the days of the Snider and Martini-Henry the average shooting of the British Army was not good. A story is told of a patent bullet-proof coat of mail being sent to Woolwich some years ago to be tested. A squad of soldiers fired ten rounds each at the coat of mail at 200 yards. On inspection, it was found that not a shot had hit the mark. At the Battle of Ulandi, British troops fired for twenty minutes at the thousands of yelling Zulus who attacked them in the open, and killed a certain number. It was subsequently calculated that only one British soldier in every fifteen killed a Zulu at all. In other words, fourteen out of every fifteen of our troops fired for twenty minutes at savages in the open without hitting any of them. There may be some exaggeration in this calculation; it is difficult to verify. But there seems to have been something wrong in a system which could produce results anything at all like this; and the faults, if any, must have been the faults of the system of training, and not of the men themselves. . . .

There are probably many really good marksmen scattered up and down the ranks of our regular, militia, and volunteer forces; and doubtless many of our officers (who till quite lately have never carried a rifle in war) are first-class shots, probably from game-shooting practice. But it is a serious question whether the general average standard of rifle-shooting is as high as it ought to be. It used to be said, and is even now held in some quarters, that it takes the expenditure of a man's weight in lead to kill him in war. If this is or was true, there is or must have been plenty of margin for improvement in the average shooting of troops, and the saying is also evidence of the very low standard of rifle-shooting accepted by some military authorities. No doubt the practical test of a standard of excellence is its comparison with others. On general principles the Transvaal burgher is bound to be a better rifle-shot than the British soldier. His opportunities have been infinitely greater. He was originally taught in the school of necessity, when sometimes his life, and usually his dinner, depended on his accuracy of aim. He lived in a wild, open country where he could practice rifle-shooting from his front door. He has thoroughly learned the lesson of the rifle in the process of killing natives and hunting big game, and may even now be said to be teaching this lesson to us in the sterner game of war. The Western American ranchman and settler, with whom I am intimately acquainted, is another instance of this skill evolved by circumstance. As an example, when the Union Pacific Railway was building through a country west of the Mississippi River swarming with antelope, many Western settlers made a living by supplying railway camps with meat. The skill these men often attained through constant practice was simply marvellous. . . . .

As regards our skilled material, I believe it exists in plenty already in a potential state among the 40,000,000 of population of these islands; but it requires cultivating and organising. It is not credible that a people who produce many rifle-range

shots of the first class (see the number of "highest possibles" recorded every year at Bisley in all the various competitions), whose healthy boast it is to excel in all athletic sports and games of skill in hand and eye, who produce by far the largest number of successful big-game hunters and crack gun-shots of any country in the world, could not also produce a reasonable proportion of mounted military riflemen second in skill of shooting to none in the world. But it is quite possible that our military authorities have not even yet realised the real effectiveness of the modern rifle in a master-hand, and how important it is to enlist and pay and cultivate that skill and effectiveness, and have it ready to hand as and when required.

For the immediate purposes of this war, and so far as our volunteers and yeomanry are concerned, a special sharpshooters' corps would, it is suggested, be a first step towards the desired end. Instead of your crack shots being scattered up and down the ranks of a battalion, let them be detailed as a special company for the battalion, and drawn from the special sharpshooters' corps. The commanding officer could then appoint them for their special work, as opportunity arose, without difficulty or disturbance of the ordinary rank and file. They should be specially equipped in various important details. First, each rifle should be as well fitted as time will allow in length and bend of stock to each individual sharpshooter. Then the pull of the trigger must be carefully considered. The regulation 7lb. pull may be all very well for the ordinary rank and file, to whom the handling of a rifle has not become second nature; but for your crack shot, possessed of special aptitude and skill, this regulation should be amended. The pull is far too heavy. A 4lb. or 5lb. pull is quite compatible with safety. As a matter of fact, I believe the regulation pull is often over 7lb. Each man should also be supplied with the best possible pair of field-glasses, invaluable for scouting purposes; and possibly with a telescope sight. These sights were, I believe, used with great effect in the American Civil War.

Lastly, the standard of markmanship for such a corps should be as high as possible. The power of shooting quickly, as well as accurately, and at unknown ranges, should be fully taken into account. This sharpshooters' corps might be mounted, and the nucleus of it taken from the present Imperial Yeomanry now being formed, of which movement it would form a part. . . . Some system of Saturday afternoon competitions, with prizes, that would appeal to the regular rank and file, might be made more common and popular. The regular course of practice should also include more quick shooting at moving objects and at unmeasured ranges. Special marks of distinction for really first-class shots might also be awarded. It looks as if the Army rifle is now about as good a weapon as science can contrive. It remains for the man whose business it is to use that rifle to be fully educated up to it.—H. SETON-KARR, M.P., in the *Pall Mall Gazette.*

COMBUSTION IN LIQUID AIR.

WHEN air is liquefied, nitrogen and oxygen condense simultaneously, so that the liquid has the composition of the gas mixture in the air. As soon, however, as evaporation recommences, the composition begins to change. At first the escaping gas is essentially nitrogen. After a while the vapours again contain the two gases in the proportions in which they are found in the atmosphere. That point occurs when about 70 per cent. of the liquid has evaporated, and 81 per cent. of the original nitrogen, and 35 per cent. of the oxygen have escaped; the remaining liquid contains the two bodies in equal proportions; afterwards oxygen begins to predominate in the vapours. These numbers concern evaporation at atmospheric pressure. In vacuo, the evaporation of the two gases proceeds more rapidly; at increased pressure, more slowly. The changes may be observed with the help of a glowing chip of wood. At first the wood will be extinguished when held over the liquid, then it will brighten up, and when dipped into the liquid burn intensely. Powdered carbon, soaked with liquid air, puffs away like gunpowder on ignition, and explodes when a detonator cap is employed. This seems very strange when we think of the exceedingly low temperature of the liquid. −180° Cent.; and in a paper brought before the Bavarian Academy of Science, Carl Linde expresses the opinion that we may have to modify our views on the nature of explosions. Petroleum, absorbed by kieselguhr or powdered cork coal, can be saturated with liquid oxygen. Such a mixture explodes even when not confined. Cartridges filled with it cause others, placed at a distance of 25 centimètres (10in.) from them to explode, whilst with the highest explosive so far known, blasting gelatine, cartridges 15 centimètres away from the detonating cartridge remain inactive. Linde has tested this preparation at Schlebusch. Within a steel bomb of 20 litres capacity blasting agents are exploded by means of fulminate of mercury. The gas pressure is registered by a piston on a drum which has a circumferential velocity of 330 centimètres (10ft.) per second. The petroleum-liquid air preparation gives a curve which demonstrates that the maximum pressure surpasses that obtained with blasting gelatine, and is reached in a shorter period of time. The preparation was simply wrapped in paper. It is singular that such a mixture should burn more rapidly, in spite of its low temperature, than any solid or liquid compound we know at ordinary temperatures.—*Engineering.*

LORD RAYLEIGH ON FLIGHT.

THE discourse delivered by Lord Rayleigh, F.R.S., last Friday at the Royal Institution attracted much attention, for the subject was "Flight." In the course of his remarks Lord Rayleigh said that the main problem of the flying machine was the problem of the aëroplane. What were the forces that acted on a plane exposed to the wind? This was also the vital problem of kites, of which he mentioned some of the practical applications by Franklin, Archibald, Baden-Powell, and others; but kites were always anchored to the ground, and as soon as we cast ourselves adrift from the ground the problem became difficult, for it was then necessary to consider how maintenance in the air could be managed. The Malay kite [see No. 1542] was, he thought, one of the simplest, but the best was that invented by Hargrave in Australia—a curious-looking affair, more resembling a skeleton box partially covered with calico than an ordinary kite. It was a very stable machine in the air, however, depending on side vanes which, when the kite got a little out of the wind, tended to bring it back again. [For illustrations see p. 238, No. 1493.] Messrs. Roche and Marvin, in America, had, he said, flown kites to very great heights, as demonstrated by self-recording instruments. The essential question in connection with the kite was the action of the wind on the aëroplane, but it was different with the flying machine, which, unlike the kite, was free and unattached to the ground. Some birds maintained themselves in the air by a vigorous flapping of the wings. Others seemed to maintain themselves in the air with little effort. What was the nature of the "soaring" or "sailing flight" by which a big bird maintained itself with but little flapping of wings? There had been much discussion about this point, often foolish because of misunderstanding between the disputants. However, the science of mechanics enabled it to be laid down with certainty that a bird could no more maintain itself without motion of the wings in a uniform wind moving horizontally than in air at perfect rest. It was entirely a question of relative motion. If, then, a bird was seen to be maintaining itself without flapping it was certain the air was not moving horizontally and uniformly. But there might be rising currents of air upon which it was supported, and these were much more common than was often supposed. In other cases where it was difficult to imagine the existence of such currents an explanation might be sought in the non-uniformity of the wind, for it was mechanically possible for a bird just at the point of transition between two different *strata* of wind to maintain its position by taking advantage of the different velocities. The albatross, he believed, did so. Langley had pointed out how the bird could turn to account the internal work of the wind by taking advantage of its gustiness.

Referring to aëroplanes, Lord Rayleigh said that if a man raised himself in the air, and he was not to fall, something must fall instead of him—that was to say, there must be a downward current of air caused by a screw, and the question was what must be the size of the screw and the work to be done in order that the man might be supported. Mr. Wenham had considered the matter carefully, and had decided that it was impossible for a man, by his own muscular power, to support himself by means of a screw. A bird had an advantage over a man in point of size, and the wings a man would require, if he were to fly with them, would have to be absurdly large. In the same way, the size of a screw would have to be out of proportion to anything that could be managed. Mr. Maxim had said the difficulty was to be got over—that it was only a question of money, and he (Lord Rayleigh) was inclined to agree with him. But even when the problem of flight was solved, flight would not be a safe form of locomotion for a lady going to London for a day's shopping. It was difficult to see how alighting could be made safe, there being always a danger of getting into gusts of wind near the ground.

MESSRS. ROBERT BOYLE AND SON, Ltd., of Holborn Viaduct and Glasgow, the well-known ventilating engineers, have issued a most elaborate catalogue descriptive of their devices as applied to buildings of all kinds, accompanied by the opinions of experts and extracts from the Press. Boyle's system has been in use now for many years, and has practically no competitor. The illustrations show all sorts of buildings, with the various methods of applying the system.

ARTIFICIAL COAL IN GERMANY.

THE United States Vice-Consul at Mannheim states that he has recently assisted at a trial to demonstrate the combustible properties of an artificial coal invented in Germany, and has observed its ready inflammability and its apparently considerable heating qualities. The inventor claims that all sorts of earth may be used for his substitute, with the exception of sand and gravel; but it is thought that only those whose component parts are vegetable or ligneous, as moor peats and turf lands, would be available. The inventor also enumerated, among suitable substances, various kinds of clay; but, in the opinion of the vice-consul, these would probably have to be used as an admixture with the vegetable soil for graduating the heating qualities of the coal. Certain ingredients are mixed with the earth and worked into a homogeneous mass for the purpose of making it inflammable. These ingredients are the inventor's secret; but, since his preparation is intended to have the properties of pit-coal, their nature can be easily guessed. They are to take the place and produce the effect of the bitumen of the mineral article, and must be substances of quick ignition and combustibility, such as pitch, resin, naphtha, or similar products. One hundred kilogrammes (220lb.) of such articles may be bought at Mannheim for about 8s. 4d.; but only 6 to 8 per cent. are required for 50 kilogrammes (110lb.) of the artificial coal. Including labour and general expenses, the cost for the quantity would be, say, 3½d. A tract of land bought lately by the inventor furnishes 50 kilogrammes (110lb.) of earth especially suited for the purpose, for about one farthing; so that 50 kilogrammes (110lb.) of the artificial coal will cost not more than 3¾d. to produce. This calculation is taken from the notes of the inventor. The cheapness will be best illustrated by comparing the prices of the various grades of pit coal, which have run in the last year from 8½d. to 1s. 1½d. per 110lb., at Mannheim. The artificial coal, of a greyish black, is pressed in blocks (briquettes) of three sizes—viz.: No. 1, 7¼in. long, 2¼in. broad, 1½in. thick; No. 2, 6¼in. long, 4in. broad, 1¼in. thick; No. 3, 3¾in. long, 3in. broad, 1¼in. thick. The blocks are hard and brittle, and when thrown into the furnace whole or in pieces, they ignite readily, and burn briskly. The suggestion that for technical establishments blocks of larger size would be desirable was answered with the statement that forms for making 10lb. pieces were already in preparation. The result of an examination of this coal by the technical assayers at Karlsruhe showed that it contained water 14·79 per cent., ashes 17·73, and combustible substance 67·48 per cent.

DIFFICULTIES IN SILVER PRINTING.

THAT much may be done to produce a good print from a faulty negative, by means of dodging in printing as well as submitting the negative to special preparation prior to its being placed out to print, is a fact well known to every photographer who is possessed of even a moderate amount of photographic experience, and it is also well known that, in the hands of an expert printer, many seemingly useless negatives can be so manipulated as to cause really serviceable prints being pulled from them.

The numerous dodges to which printers resort in dealing with faulty negatives are now and again trotted out in the different handbooks and other photographic literature, very much of which all run in the same groove, and too often savour of an amateurish nature, for professional printers know when to keep a good thing up their sleeve quite as well as anyone.

That a deal may be done to improve the printing quality of a negative by subjecting it to one or other of the common everyday dodges, such as the application of ground glass or mineral paper to certain parts of its surface, and also by reducing over-density by any of the well-known methods so generally practised, is a fact recognised by everyone; but, as a rule, all our handbooks and guides to photography stop here, leaving a student to worry over an indifferent-printing negative, and which, in his hands, is never capable of being made to yield anything like the results an expert printer can produce, simply by reason of the fact that the expert printer carries his treatment of a faulty negative a long way further than many might imagine.

During recent years the production of special photographs for reproduction by means of half-tone blocks has caused the utmost attention to be devoted to this branch of photography, and it is quite surprising what is now capable of being accomplished in the way of turning out high-class results from indifferent negatives.

Take, for instance, the case of a dimly-lighted interior, in which a stained-glass window forms a prominent object in the view, the details of which are required to be faithfully rendered as well as the architectural features of the building surrounding

the window, and we have a by no means easy subject to photograph without special means of lighting, only practised by a few expert architectural photographers. Even with their special knowledge of how best to photograph such a subject it is quite ten to one the negative they produce will be considerably improved by after-manipulation. But it is not only in the treatment to which such a negative is subjected that much of the final success in reproduction lies—there is what may be termed an intermediate stage of dodging not only the negative during its printing, but a very clever system of treating the actual print (during the time it may be said to be printing) in such a manner as completely stops the printing of those parts that are being overdone before the denser portions gain a sufficiency of depth. To many not experienced in printing difficult negatives this may appear almost an impossibility; but, as everything is easy when you know how to do it, so such a method of treating a faulty negative gives little thought or trouble to an expert printer.

When it is impossible to produce a fairly even print by means of ordinary printing, one of the most effectual means of gaining satisfactory prints from an uneven negative will be found to consist in subjecting those parts of the surface of the silver prints that are being over-done to a blocking-out operation, performed by applying a suitable water-colour pigment where it is desired to stop any further action of light. Many young printers, although quite appreciating the *rationale* of such a method, fail to understand how it is possible to obtain possession of a silver print so as to apply to its surface such a pigment in as careful a manner as is necessary without the removal of the print from the surface of the negative, and the consequent liability of being unable to register it in exactly the proper position, so as to avoid even the slightest semblance of what is termed movement in a printing frame.

In practice, however, there is no real difficulty in accomplishing such an operation, and, once a printer has ocular demonstration of this treatment of a print, he for all time coming would never think the operation a difficult one.

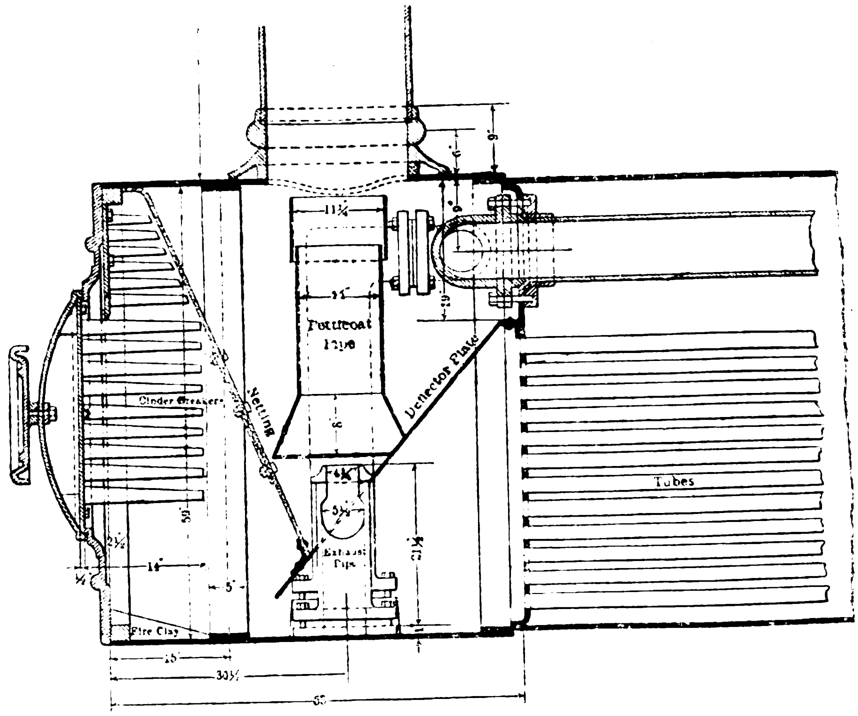
To carry out this seemingly difficult printing dodge, the negatives should be printed in frames a size or two larger than that of the negative itself. This is best accomplished by attaching the negative to the centre of a thick sheet of glass by means of strips of gummed paper, binding carefully round its edges, so that it will not move during the time it is in the printing frame. This done, the negative will be found firmly attached to a sheet of glass having a margin all round its sides. This margin is of service in the way of permitting a sheet of paper being used in printing that is larger in size that the negative, and will enable the side or one end of the printing paper being gummed or otherwise firmly attached to the glass support in such a manner as will permit of the negative and its glass support being removed from the printing frame as often as may be desired during the time of printing, so that the most careful examination of all portions of the surface of the print may be made.

The printing paper being of considerably larger size than the negative permits of the print being folded over. After the negative and its support are removed from the printing frame, when folded over, it enables any water-colour pigment, such as gamboge, or ivory, or lamp-black being carefully painted over the very finest part that may require to be stopped off from further printing, and, when the pigment is dry, the print is merely folded down in contact with the surface of the negative again, with the certainty of being in perfect registration. Of course, the application of the pigment is best conducted under a good lamp, such as a powerful paraffin table lamp would yield in a darkened room. This prevents any degradation of the paper during inspection and manipulation. The painting of an opaque pigment on the surface of a silver print will cause no evil effects to the print, for the pigment will wash off in the first washing water, and the toning operation proceed as usual, and there is also no difficulty in tracing over the minutest outline if merely an ordinary amount of care be taken, and a suitable brush employed.

By this means an expert printer is possessed of almost unlimited power in the production of single as well as even combination prints. Faulty backgrounds being blocked out in the negative will enable any portion of a picture being printed on one negative to any extent, and, this being blocked off on the surface of the print, may then be removed to another negative, and quite a different background printed in.

The secret of success lies in so attaching the print to the surface of the glass support that the entire surface of the printing-paper is capable of being got at without the possibility of the image showing any movement from the surface of the negative when readjusted.

To many this method of printing a negative may be considered difficult. In practice, however, it is quite easy of accomplishment, and, once practised, can be made to yield quite a number of particularly fine prints from negatives that would by many be discarded as unprintable.—T. N. ARMSTRONG, in *British Journal of Photography.*



COBURN'S SPARK BREAKER.

WE present herewith a cut of the arrangement applied to the front ends of the locomotives on the Chicago, Indianopolis, and Louisville Railway, the Monon route, to break up and pulverise the cinders, so that when they finally get to the ground after leaving the top of the stack, they will be too small to do much damage by setting fires. The front-end deflector plate, nozzle, and petticoat pipe are of the Master Mechanics type, with a low nozzle. It is shorter than usual. Between the netting and front door in this space are a series of fingers, cast on a plate, extending close to the netting. These fingers are 14in. long at the bottom and shorter near the top. The effect of the draught dashing the live cinders against the fingers is to break them up and kill them. Two years' trial has demonstrated the value of this device in reducing the fire claims of the road over 80 per cent. It is patented by W. P. Coburn, master mechanic.—*Locomotive Engineering*, N.Y.

THE LANCASHIRE PLATEWAY.

AT the Walker Engineering Laboratories, University College, Liverpool, Mr. Alfred Holt, M.I.C.E., read a paper last week on the proposed Lancashire Plateway—a scheme which has occupied the attention of the commercial community of Lancashire for some time. Prof. Hele-Shaw was in the chair, and Mr. Holt explained at the outset of his paper that though it referred to the "Lancashire" plateway, it was really a paper on the system, which seemed to carry with it nothing less than an entire revolution in inland carriage. Having glanced at the mercantile necessities which gave rise to the idea, and also originated the Manchester Ship Canal, he said the basis of the plateway was simply a railway suitable for a smooth-tired wheel. Ordinary railway traffic might traverse the plateway metals, which formed, in fact, as good a railway as any other; and that being so, it would be advisable that the new system, if ever introduced, should be on lines to escape some of the present railway disabilities, such as the cramped loading gauge. This should be a foot wider on each side, and 1½ft. or 2ft. higher overhead; some other countries had a great advantage over England in that respect. Also, everything should be suitable when used as a railway for much heavier loads than at present carried, 40 tons in the way of minerals, metals, corn, &c., being often carried in one waggon in the United States, and economy resulted. Having demonstrated (1) the identity of the rolling conditions of the plateway and the railway, and (2) the fact that the plateway is a railway, Mr. Holt said it would be apparent what an unfortunate name plateway was, for of plate there was not a vestige. A better name would be "Railway suitable for vehicles with both flat and flanged wheels," and the word "Barway" had been suggested, which was not bad. So long as the engine kept on the metals, which having flanged wheels would always be the case, it did not much matter if the lorries occasionally ran off. The vehicle was proposed to be the ordinary four-wheeled lorry. If suitability for moving goods was to be taken as a test, and surely there could be no better, it was a long way ahead of the railway waggon. The differences between them were in the main two: (1) In the lorry the fore wheels lock—that is to say, are attached to an under carriage—which supports the fore end of the load, and is capable of being turned to any angle with the vehicle. (2) All the wheels are loose on stationary axles. On railways the wheel is fixed on the axle, and both revolve together. As the system could not be considered to meet the necessities of the case unless trains as long as those on a railway could be made up, he explained that the proposed coupling method was not dissimilar to that adopted in coupling road trucks behind a traction engine. Having only proposed a speed of ten miles an hour, spring buffers were probably unnecessary. The practical mode of carrying goods by the plateway would be as follows: The lorry, being loaded at the ship's side or warehouse in Liverpool, would be horse-drawn, exactly as at present, to the nearest plateway lines, placed on them, if convenient, or, at any rate, near to them; the long horizontal shaft bolt would be withdrawn, and the horse would be driven off, carrying the shafts with him. The iron coupling frame would then be unhooked from under the fore body of the lorry, and one end of a rope made fast to it, the other end carried either to the hinder part of the engine or of the preceding lorry, or else taken to a live capstan, and by one of these means the lorry would be pulled into position, the short vertical coupling bolt would be dropped in, and the transformation would be completed. Mechanical traction by steam, or preferably by electricity, would then convey it as part of a long train, say, to Manchester, where horses, which would be standing waiting, having brought other lorries for Liverpool, would be led up, the coupling frame would be again hooked up under the fore body, the shafts attached, and the lorry again horse-drawn to destination at either mill or warehouse, its load never having been touched. Probably between Liverpool and Manchester, where there is an enormous traffic, the road would ultimately come to be paved the whole way. Horse-drawn traffic would then come on anywhere, run on the metals five or ten miles, and then drawn off. Lord Derby would dine at the Liverpool Town Hall, and go home to Knowsley in his carriage, using the plateway. The slow plateway claimed over moderate distances to deliver in less time than the speedy railway. Mr. Barcroft, of Newry, noticing his (Mr. Holt's) project, built a plateway of about three miles in length from Newry to Bessbrook some fifteen years ago. The line was, he believed, still at work. Regarding the public advantages of the system, it had been pointed out how it would affect the Lancashire trade; but there was a greater interest it would affect in a greater degree, and that was agriculture. Railways had never helped the farmer: the merest fringe of his requirements had been touched. Owing to the difficulty of carrying hay, for example, its price had been known to differ 20s. a ton in places 30 miles apart with a railway between them. Then why should great coal-yards like those at Crown-street exist? It was to be hoped that the plateway system would develop as a road trust, while lorry-hiring companies would come into existence with

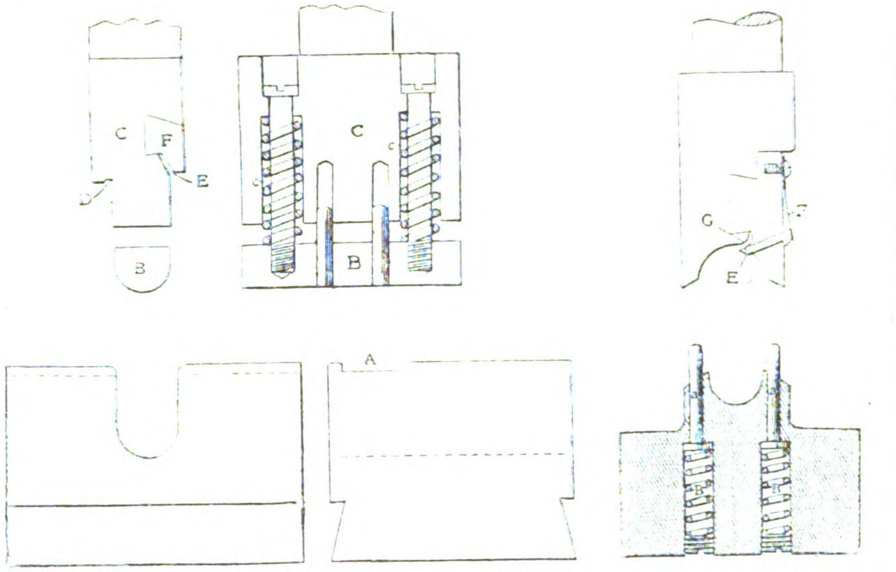


Fig. 2

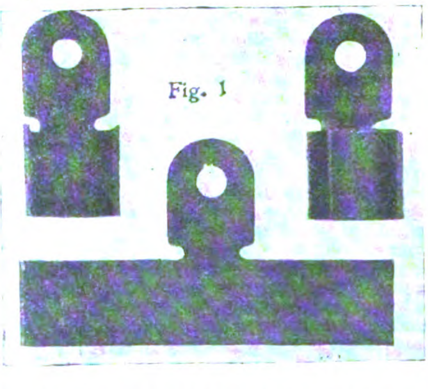
Fig. 3

depots up and down the country at which they would keep standard lorries for different classes of traffic. He concluded by a short recapitulation of the points he wished to make. They were:—(1) That railways attained their remarkable success over previous methods of land carriage by the adoption of two novelties—(a) The metal pathway; (b) mechanical traction; and from their combination resulted almost the cheapest known method of moving goods. (2) That both are equally applicable to vehicles with flat as with flanged wheels. (3) That flat wheels can also traverse the ordinary roads, which flanged wheels cannot. (4) That, therefore, handling is saved, which has been demonstrated to be the largest component part of the cost. (5) That the plateway system which avails of these is in the present state of mechanical knowledge the *ne plus ultra* for cheap and undamaging conveyance.

SPECIAL BENDING-DIE.

OF the different classes of dies in use for the press working of sheet metal, probably there is none that taxes the skill and inventive powers of the mechanic more than those commonly known as bending-dies. There are rarely two alike; the one you are working on usually differs in some respects from all previous designs; each punch and die is a law unto itself, and after completion it is dismissed from one's mind, to be followed by something new.



The peculiar or special feature of each job, however, is generally recorded in the notebook of the up-to-date die-maker for future reference.

The accompanying sketches show two punches and dies that we have recently made, to bend a piece of flat copper 2¼in. long, ⅛in. wide, and ·025in. thick, into a circular form with an irregular contour and overlapping ends, the outside one being flared outward at the extremity. A sample blank and the two stages of the bending operation are shown in the half-tone, Fig. 1. On one side of the blank, almost in the middle, will be seen a projecting part, that, according to the specifications, must be flat, and unaffected by the bending operations, and also central with the loop.

Following the regular experiments to ascertain the size and shape of blank required, the piercing and cutting die is made, and requires no description here.

Fig. 2 is a sectional and front view of the punch and die for performing the first bending operation, which comprises the bending of the ends up, not unlike a letter U, with the highest end turned inwards, the bend being about $\frac{1}{16}$in. from the top. The blank is placed in the recess A, Fig. 2, which acts merely as a gauge for locating it sideways; stops for the ends are ⅛in. pins, not shown. The work is brought well forward, to allow the projecting part to stand out over the front of the die, to avoid bending when the other part passes down into the die. The downwardly-extending portion B of the punch is held stationary by the coil-springs, C C, until it comes in contact with the bottom of the die. As the ram of the press continues on the downward stroke the notch in the shoulder at D strikes the end of the work on that side, and forces it down to its proper height, thus securing uniformity. At the same time the opposite end of the blank is passing into the slot E, and bending inwardly. F is a dovetailed piece, to facilitate the making of the slot E in the punch.

It is a good plan in this case to locate in the bottom of the die, in rear of where the work comes, a strip of sheet metal or a rigid pin, the same height as the thickness of the stamping, to permit the punch to rest on. This will prevent a hard pressure on the work, and allow it to slide round under the punch and avoid buckling when the shoulder at D presses on that side to correct the height.

Fig. 3 shows the closing punch and die. Following the first bending operation, the work is located on the die between the two pins, A A, that hold it in its proper position for closing. The pins are supported by slender coil springs, B B, which are regulated by the headless screws below them. Screwed and dowelled onto the middle front of the die is a small block of cast iron, not shown, with two pins, one on each side, to guide the pivoting part on the work during the closing of the circle. On the descending movement of the punch the pin E gives a slight pressure on the work, and causes the end, that has been previously bent in at its extremity for this purpose, to pass on the inside. The pin is retained in position by the flat spring F. As one end of the stamping goes down on the inside, the opposite one follows along the punch until it comes in contact with the upper surface of the pin E, when it is forced to pass up into the groove G, and bent outwardly. The use of a round arbor is necessary in this operation to size the circle in the work.—DIE MAKER, Lynn, Mass., in *American Machinist.*

MESSRS. ROSS, Ltd., of New Bond-street, W., send some useful catalogues of their productions—telescopes, microscopes, and of binocular glasses. The latter are just now much talked about; but, as all students of the question are aware, there are no more powerful glasses of the kind than can be supplied by Ross, Ltd.

M. PICARD, Commissioner-General of the Paris 1900 Exhibition, has been informed by the president of the jewelry section that an enormous diamond from Kimberley will be exhibited in the jewelry pavilion. The stone was found shortly before the war. It has been insured for £400,000, and will be shown in a showcase guarded by four policemen. At night the showcase will sink into the ground in the same way as that in which the Regent is kept at the Louvre. The new diamond is said to be finer than the Regent, the Shah, the Grand Mogul, and the famous Koh-i-nor.

SCIENTIFIC SOCIETIES.

ROYAL METEOROLOGICAL SOCIETY.

THE annual meeting of the society was held on Wednesday evening, the 17th inst., at the Institution of Civil Engineers, Great George-street, Westminster, Mr. F. C. Bayard, LL.M., president, in the chair.

The secretary read the report of the council, which showed that the most noteworthy event in connection with this society had been the removal of the offices and library from 22, Great George-street to new rooms at 70, Victoria-street. This step was rendered necessary by the acquisition of the former premises by the Commissioners of Her Majesty's Works and Public Buildings for the erection of new Government Offices.

Mr. F. Campbell Bayard, in his presidential address, discussed the meteorological observations made at the Royal Observatory, Greenwich, during the fifty-one years, 1848-1898, and brought out in a novel way many interesting features in the variability of the different observations of the barometer, maximum and minimum temperatures, relative humidity, direction of the wind, and rainfall. These were shown in a diagrammatic form on the screen by means of a number of lantern slides. The address was also illustrated by various views of the Royal Observatory and of the instruments employed. Mr. G. J. Symons, F.R.S., was elected president for the ensuing year.

QUEKETT MICROSCOPICAL CLUB.

THE 374th ordinary meeting of this club was held on Friday, Jan. 19, at 20, Hanover-square, W., Dr. J. Tatham, president, in the chair. After the usual formal business, the list of nominations made by the committee was read as follows:—For president, Mr. George Massee, F.L.S.; for vice-presidents, Messrs. Tatham, Waller, Michael, Nelson; for treasurer, Mr. H. Morland; for editor, Mr. D. J. Scourfield; the other officers as before. Messrs. Allen and Chapman were elected as auditors. Members were nominated to fill six vacancies on the committee. The death of Mr. W. T. Suffolk, treasurer R.M.S., was referred to, he having been one of the earliest members of the club, and taking an active part in its proceedings for some years.

Mr. Nelson exhibited and described three so-called "compass" microscopes, fitted with Coddington lenses, and said to have been made for the late Mr. J. Newton Tomkins.

Mr. Rousselet read "Notes on some Australian Lacinulariæ."

A short paper "On the Minute Structure of some Diatomaceæ from Corica Bay, Melbourne," by Mr. A. A. Merlin, was, in the author's absence, read by the secretary.

Mr. Karop gave a brief account of some recent biological observations and other matters of scientific importance.

Votes of thanks were passed for these several communications, and the proceedings terminated.

The next meeting, which is the annual general meeting for the election of officers and other business, will be held on Friday, February 16.

Trees Struck by Lightning.—Under this title, Mr. Howard B. Little, in *Knowledge* for January, discusses some remarkable cases of trees shattered by the dread stroke, for particulars of which the original article should be consulted, but we may quote here a single passage:—"P. de Jersey Grut gave particulars of a case which is perhaps more interesting than any yet cited. In this instance the tree struck was encircled by a rope some 25ft. from the ground, and it so chanced that an end of the rope stood out from the bark of the tree, so that during the earlier part of a rainstorm the tree was damp from the top to the rope, while the lower portion of the trunk was kept comparatively dry. The tree in this condition was struck, the lower part only being damaged. And the damage followed, downwards, a path which the twist in the fibre of the wood made easiest."

THE effects of wire-drawing and annealing on the stress-strain diagram of steel wire have been studied by Mr. A. D. Keigwin, and the results given in the *Proceedings* of the Institute of Civil Engineers. The conclusions are:—(1) Steel when wire drawn has its breaking load increased. (2) When the wire is annealed, the breaking load is lowered to that of the billet from which the wire was drawn; in this case an average reduction of 39 per cent. (3) The ratio of yield point to breaking load—36·7 and 31·8 per cent. for unannealed and annealed wires respectively—is lowered. (4) The ratio of the extensions at yield point and at breaking load in unannealed wire—viz., 0·25 to 0·75 per cent., is increased by annealing to 0·25 to 5 per cent. (5) The reduction of area of break is increased 16 per cent. by annealing. (6) The mean stress-strain diagram for annealed wires is a parabolic curve.

SCIENTIFIC NEWS.

THE elements and ephemeris of the new minor planet known as 1899 E Y are given by Herr O. Knopf, of Jena, in *Ast. Nach.* as M 345° 32′ 15·3″, ω 3° 32′ 19·9′, ☊ 39° 46′ 43·3″, *i* 15° 22′ 20″, epoch 1900, Jan. 0·0, Berlin M.T. The ephemeris for Berlin M.T. 12h. is on Feb. 3 R A. 4h. 11m. 19s., N. Dec. 19° 1·9′.

The Spanish Government will make the best possible arrangements at the Madrid Observatory for the reception of foreign astronomers who will come to observe the eclipse of the sun on May 28. Nevertheless, says a Reuter's telegram, other places are better adapted for the purpose, as, for example, Naval-Moral, two hundred kilomètres from Madrid on the Caceres Line, because at that place the eclipse will be total for two minutes. Several foreign astronomers have expressed their intention of coming to Spain to witness the eclipse.

For the larger number of those who desire to observe, the convenience of getting to the best spots is the chief consideration, and probably nothing could be better than the arrangements made by the British Astronomical Association, the vessel calling at Cadiz, Alicante, and Algiers, the former place for those desiring to pay a visit to Central Spain. Hotel accommodation has to be considered, but vessels touching at Oporto would suit some observers, as the line of totality passes close (at Oveiro); but there are reasons why Oporto will not be chosen, except by those who may have business there at the time.

The 67th *Annuaire* de L'Observatoire Royal de Belgique (Brussels: Hayez) has been issued under the direction of MM. A. Lancaster and L. Niesten. It contains the usual calendars and tables, statistics of various kinds, and several articles which are of interest to astronomers.

M. Poincaré has been awarded the gold medal of the Royal Astronomical Society for his researches in celestial mechanics.

The following note may be of interest to those who study the effects of the sunspots and of the moon on the weather. Mr. T. F. Summerhayes writes from Dominion Bank Chambers, Toronto: "A letter appeared in the *Times* in December from Mr. Payne of the Meteorological Office, Toronto, to which you append the following:—'We gladly print Mr. Payne's letter to show that "Our Lady of the Snows" is a title that cannot be applied, at any rate to that part of the Dominion from which he writes.' By the same post I received a letter from the North-West Territories in which the writer says 'We have not even enough snow to be able to use the sleighs.' Apparently the title cannot be applied there either. It is an interesting addition to Mr. Payne's facts that the bushes surrounding Trinity College Buildings, Toronto, were in the middle of December budding again, and had lectures lasted another week I should probably have been able to say they were in leaf. Although a heavy snowstorm has blocked traffic in England (Dec. 11), we have had no snow worth the name. I may say, however, that the lack of snow is likely to seriously hamper the farmers and lumbermen. The former need snow to protect their fall (i.e., autumn-sown) wheat from the frost: the latter to haul their felled trees over the otherwise uneven ground to the river banks." It may be noted that it was only in parts of England the traffic was blocked.

The Geological Society will this year award its medals and funds as follows:—The Wollaston Medal to Prof. G. K. Gilbert, of Washington; the Murchison Medal to Baron A. E. Nordenskiöld, of Stockholm; the Lyell Medal to Mr. J. E. Marr, of Cambridge; the Wollaston Fund to Mr. G. T. Prior; the Murchison Fund to Mr. A. Vaughan Jennings; the Lyell Fund to Miss G. L. Elles; and the Barlow-Jameson Fund to Mr. G. C. Crick and Prof. T. T. Groom.

At the Royal Institution, to-day, the Hon. C. A. Parsons, M.A., F.R.S., is to deliver a discourse on "Motive Power—High Speed Navigation—Steam Turbines." On Friday, Feb. 2, Signor Marconi is to deliver a discourse on "Wireless Telegraphy."

At the Tuesday evening meeting of the Applied Art Section of the Society of Arts, Jan. 30, a paper on "Niello Work," by Mr. Cyril Davenport, will be read. The paper on the Wednesday evening meeting, Jan. 31, will be by Sir Martin Conway, M.A., on "The Undeveloped Resources of the Bolivian Andes."

Our readers will regret to hear of the death of Prof. David Edward Hughes, F.R.S., the famous inventor of the type-printing telegraph and of the microphone. He was born in London, May 16, 1831, but spent much of his earlier manhood as professor of music at Bardstown, Kentucky. In 1855 he patented the type-printing telegraph, and brought it to this country, where it met with a cold reception; but the French authorities saw its advantages, and honours soon began to be the reward of the inventor. In 1878 Prof. Hughes described to the Royal Society his invention of the microphone, and, as our readers may remember, a lively discussion was carried on in these pages by Mr. Edison, Mr. Preece, and Prof. Hughes. The deceased inventor was awarded the gold medal of the Royal Society and the Albert Medal of the Society of Arts.

The death is reported from Florence of Mr. John Bernard Stallo, of Cincinnati, in his seventy-sixth year. He was formerly Ambassador of the United States at Rome during President Cleveland's first term of office, but since his retirement has resided at Florence. He was well known as a philosopher, mathematician, and physicist.

News from Cracow states that M. Kostanecki, assistant doctor at the bacteriological institute there, has died with symptoms of plague. A later telegram states that an investigation has revealed the presence of a very infectious form of streptococcus.

Signor Manfredo Camperio died at Naples recently, in his seventy-fifth year. He was originally a Sardinian cavalry officer, but after his retirement he founded the Italian Society for the Commercial Exploration of Africa, and became well known as a geographer and traveller.

Prof. William Hauchecorne, principal of the Berlin Academy of Mineralogy and chief of the Prussian Geological Survey, died last week at the age of sixty-eight. He was the author of several works on metallurgy.

In a memoir presented to the Paris Academy of Sciences by Mme. Sklodowska Curie it is stated that there is a difference of a fundamental nature between those rays of radium which are deviated by the magnet and those which are not. The latter, it appears, are more easily absorbed the greater the thickness of the material they have passed through, while the deviable rays have a coefficient of absorption which either decreases or remains constant—a singular phenomenon in absorption different from other known radiations.

The Paris Academy of Sciences have elected M. Zeuthen, of Copenhagen, and M. Peron, of Auxerre, as correspondents in the room of the late M. Lie and M. Matheron.

Some very definite opinions were expressed last week before the Departmental Committee on Preservatives and Colouring Matters in Food. Prof. W. H. Corfield, consulting sanitary adviser to Her Majesty's Office of Works, said he had found salicylic acid in the lighter wines—British, for instance—and the lighter beers. It was a slightly acrid, irritating substance, which was used externally for the removal of corns and warts. He knew it did that. It was a most undesirable article to put in food. He advocated the prohibition of both boracic acid and salicylic acid, unless it was clearly shown that the drug was perfectly harmless in any quantity in which it was possible that it could be added. Mr. Walter Collingwood Williams, a public analyst for a number of Lancashire authorities, said he had found salicylic acid in a number of temperance, non-alcoholic drinks. In ginger wine there was from 49 to 113 grains per gallon, in raspberry wine from 87 to 133 grains per gallon, in orange wine from 94 to 106 grains per gallon, and in black-currant wine from 47 to 140 grains per gallon. He also found it in lemon-squash and lime-juice. The use of boracic acid in new milk is strongly objected to by many of the witnesses, as that kind of milk forms a large part of the food of invalids and children. The chairman of a firm of well-known jam manufacturers said they never used preservatives, but they did use cochineal as a colouring medium for jams.

It has been stated that Signor Marconi has satisfied himself that he can utilise his system of wireless telegraphy over the greatest distances, and now it is announced that Signor E. Guarini, of Puglia, can do the same. He is quite a young man, and has studied electricity with much ardour. According to such accounts as have been published, his invention is called a repeater, which receives the electric waves and is capable of transmitting them to other repeaters for continuous repetition. There need only be a repeater at every five-hundredth mile in order to establish communication with any given point of the surface of the earth. One of the many contemplated applications of Guarini's repeater is its use in future Polar expeditions, the commanders of which will, it is claimed, be able to maintain constant communication with home.

Similar statements are made in connection with the name of M. Nikola Tesla, who is reported to have completed his experiments, and to have satisfied himself that he will be able to communicate from New York with every city in the world. He hopes, it is reported, to "attain a speed of from 1,500 to 2,000 words a minute."

Experiments have been made with wireless telegraphy between Chamounix and Mont Blanc, and they have been recently described by MM. Léon and Louis Lecarme before the French Physical Society. As previously mentioned, there are great, if not insuperable, difficulties in achieving complete success, though the experiments gave satisfactory results. The brief account is published in the *Bulletin* of the Society, and the principal difficulties are—the difference in altitude between the two stations, the influence of cloud layers, the intense electric phenomena which occasionally occur at high altitudes, and the effects produced by the three-phase currents employed in the lighting installation at Chamounix. It is proposed to utilise those currents in future experiments.

According to a report coming from Sheffield, the corporation, after spending many thousands of pounds on their overhead electric tramways, are about to experiment with the invention of a Sheffield man to improve surface and contact system of electric traction, which, if successful, will abolish overhead wires and street standards. First and second-class car fares will be recommended for adoption shortly, on the ground that well-dressed people object to sit next to working men who are grimy after their day's toil.

Amongst the electrical railway schemes to come before Parliament in the session is one for the construction of an electric express line between Manchester and Liverpool. The proposed capital is two millions sterling.

The electric railway in the Isle of Man, between Douglas and Ramsay, has been fitted with hydraulic plant for working during the winter months, when there is comparatively little traffic. The works are at Laxey, where the famous water-wheel is a sight for tourists.

Mr. J. B. Carruthers, F.L.S., has been selected by the Colonial Secretary for the appointment of mycologist to the Government of Ceylon, and assistant-director of the famous botanical gardens at Peradeniya. The post has been created in order that the diseases of economic plants in the island (e.g., coffee and tea) may be thoroughly investigated.

At a meeting of the British Ornithologists' Club last week, Dr. R. Bowdler Sharpe exhibited some interesting views taken during a recent trip to Norway, one of the greatest interest being a brood of young woodcocks showing the striped down. Mr. Walter Rothschild, M.P., exhibited some views taken by one of his collectors in the island of Laysau. The first showed a number of albatrosses of a new species, which he has named *Diomedea immutatus*, from the fact that the plumage of the young, contrary to what is usual, resembles that of the adult. He also exhibited a picture representing the wholesale fashion in which the eggs of the albatross are collected—a number of railway waggons drawn up, and a band of men loading them with eggs, which are used as food.

Amongst the schemes for utilising fish is one for establishing a sturgeon fishery at the mouth of the Garonne, which is one of the rivers frequented by the sturgeon. The principal object is the production of caviare (the salted roe), but no doubt the flesh of the sturgeon will be prepared for the market in some way.

Australian papers give accounts of an unprecedented plague of cuttlefish that has been for a time entirely upsetting the fishing industry in North Australian waters. It is reported that the creatures are swarming in such numbers that hundreds are brought up in a single haul of the

nets. As the haul is drawn up they cling with their tentacles to the under side of the boat, and have to be disengaged with axes, so that large quantities of tackle have been destroyed and many boats injured. They range from 15lb. downwards in weight, and their appearance in such huge numbers has been as sudden as it has proved unpleasant.

A trial of the Laffas system of preventing railway accidents by applying the brakes automatically was made last week at Barry. The testing train consisted of an engine and nine coaches, weighing altogether about 160 tons, and the first tests were on the down slope of a slight incline. At a speed of 20 miles an hour the train, after contact with the Laffas block, stopped in 146 yards, at 30 miles in 200 yards, at 35 miles in 210 yards, and in a fourth test at 30 miles speed, steam being kept up, the train stopped in its own length. On the flat at a lower speed the train stopped in less than its length. The apparatus may be briefly described as a block placed in the 4ft. way, and set by the signalman. It has a curved surface, which, when the signal is standing at danger, is so raised that a rod with a little wheel makes contact and actuates the valve of the air brake placed either on the engine or on one of the coaches. Further experiments are to be made.

USEFUL AND SCIENTIFIC NOTES.

THE gold yield of Victoria for the year 1899, amounted to 854,500oz., being an increase of 17,242oz. as compared with the preceding year.

Magnesium Paper.—The following method of making magnesium paper may be useful to some, as it is easily carried about, and the intensity of the illumination may be regulated by the quantity of paper burnt. Two sheets of paper should be coated with starch paste, and then dusted with powdered magnesium, and the two surfaces pressed into contact. Two sheets are also prepared in a similar manner with powdered chlorate of potash, and then pressed on the outside of the magnesium sheets.

THE aggregate rainfall during the year just closed was deficient over the whole of England, the deficiency amounting to 6in. in the Channel Islands, 5in. in the south of England, and 4in. in the east and south-west of England. There was a slight excess in most parts of Scotland and Ireland. The mean temperature for the year was in excess of the average over the whole area of the British Islands, the excess being greatest over the southern portion of the kingdom, although it was also very large in the north of Scotland. There was an excess of sunshine over the entire country, amounting to about 350 hours in the south of England, and exceeding 200 hours over the whole of England, except in the north-eastern district. In Ireland the excess was about 150 hours, but in parts of Scotland it was not so large.

Polyphase Electric Generators.—The polyphase alternating current system is specially adapted to the distribution of light and power from central stations, and polyphase generators are being largely introduced for this purpose. The Westinghouse Company is bringing out some improved belted generators of this type, with high efficiency and close regulation of potential. They are wound to deliver either two-phase or three-phase currents. The lower half of the field and the supports of the bearings constitute a single casting. The pole-pieces are of soft laminated steel, cast into the field yoke or frame. A special grade of soft steel is used in the armature coil, and the construction is such as not to injure the steel, which would increase the losses due to magnetisation. The armature coils are held in slots by wedges of hard fibre, driven parallel with the shaft. No band wires are used, and the field and armature coils are wound upon moulds or formers. In the machines of 220 and 440 volts the armature conductors are copper bars, held in place by the overhanging tips of the armature teeth. The bars are united into a common winding by suitable end connections. The armature winding is of the closed circuit type. In the two-phase generators connection is made to the winding at four points, an insulated conductor conveying the current from each of these points to one of the four collector rings. In the three-phase generators there are three points of connection and three rings. On all sizes smaller than 180 kilowatts the fields are composite wound. The current which passes through the auxiliary field winding is not the high potential current generated in the armature. It is a low potential current derived from the secondary of a series transformer, consisting of primary and secondary coils wound upon the arms or spokes of the armature coil. The small commutator used to rectify the derived secondary current which excites the auxiliary field coils is carried upon the armature shaft.—*The Engineer.*

LETTERS TO THE EDITOR

[*We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.*]

All communications should be addressed to the EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

*** *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks; a vice from whence great inconveniences derive their original."—*Montaigne's Essays.*

[43244.]—THERE is surely some curious mistake in the first paragraph of your "Scientific News," on p. 490. I have just seen the latest volume of the *Connaissance des Temps*, in which, as in the *Nautical Almanac*, the day is reckoned—as it always has been—from noon to noon. An attempt which was made, unofficially, some few years since, to assimilate the astronomical and civil modes of reckoning (i.e., from midnight to midnight) fell through entirely.

In case "Ell Hay" does not reply to one query which "Neptune" puts in letter 43190 (on p. 493), I mean that concerning the calculation of the ephemerides of the Satellites of Jupiter, Saturn (Uranus), and Neptune, I should like to say that such ephemerides are computed, one and all, in the *Nautical Almanac* Office, those of Jupiter's Satellites from Damoiseau's tables (now 64 years old!), those of the Satellites of Saturn from Prof. Newcomb's MS. tables, and the elongations of the Satellites of Uranus and Neptune from Newcomb's "Uranian and Neptunian Systems." But "Neptune" must forgive me for pointing out that he is labouring under a slight mistake in his assumption that these ephemerides were calculated by the late Mr. Albert Marth. What that wonderful computer used to produce were ephemerides for physical observations of the planet Jupiter itself, of Mars, and of the Moon, &c., and in this he has a most worthy successor in the person of Mr. A. C. D. Crommelin, F.R.A.S., of the Royal Observatory, Greenwich.

When "Mark" (letter 43197, p. 494) was reading the account of the liquefaction of atmospheric air by intense cold, he somehow seems to have skipped that part of the description of the process which refers to the simultaneous stupendous *pressure* of 300 atmospheres, or so, being employed to produce the liquefaction. Now the mass of the moon is only $\frac{1}{81 \cdot 7}$ that of the earth, and one would be a little curious to know whence "Mark" gets his pressure?

Mr. Watson (letter 43199, p. 495) is quite right in his assumption that January 0 in *Nautical Almanac* (*loc. cit.*) does mean December 31, 1899, because January 1 does not begin astronomically until the Greenwich Mean Noon of that civil day, and for purposes of calculation it is simple and convenient, not to say absolutely necessary, to employ a zero, even if, as in this case, it is merely an artificial one. As for the use of the 0 on p. 592, it must be remembered again that the object of the table there given is to enable the number of *days* which have elapsed at mean noon at any given date since January 1, 4713 B.C., and for this purpose 1 B.C. followed by 1 A.D. would involve an obvious muddle by introducing one year, or 365 days, too many in reckoning from, say, January 1, 13 B.C., to January 1, 1802 A.D., which interval is really 1,814 and not 1,815 years, and so on. But I fail to see that the 1900·0 has any different meaning on pp. 1 and 290—*et seq.*; for, taking the first page as an illustration, we find that from 1900·0 to the noon of January 1, 1900, the precession in longitude = 0·69", which, assuming 1900·0 to be = 1900, January 1 noon, is absurd.

"W. B.'s" suggestion (in letter 43204), p. 496, is Delicious (with a capital D). Tommy Atkins is to be got up in greaves, and to have to toil up steep hills, with a shield, at the rate of three miles an hour! Moreover, he is to be attended by his rear-rank man, who is to carry his rifle—for all the world like a keeper who follows with one's second gun at a battue. Does it occur to "W. B.," *in limine*, that this would involve the doubling the numbers of our troops, and necessitate the despatch of, say, 100,000 men to do the work of 50,000. As in the case of Mr. Lawler, it is abundantly evident that your correspondent's military knowledge might almost be algebraically described as a − quantity.

I could not help laughing at letter 43225 (on p. 512), when I read that Mr. Lawler's shields were "actually receiving the practical attention of . . . a man who has had more to do with wholesale manufacture of armour-plates than"—anyone Mr. L. knows! "There is nothing like leather." I spoke merely from a practical point of view, and can assure Mr. Lawler that he is labouring under a very curious delusion when he imagines that "Shields would have taken us to Ladysmith and Kimberley long ago."

I hope, though I may be pardoned for doubting, that "Argentine" (queries 97352 and 97353, p. 479) may be edified by the replies of "Regent's Park" on p. 500. I wonder whether the gentleman who adopts that *nom de plume* ever made an observation to determine longitude in his life; or whether he has any practical acquaintance with the theodolite, the only instrument, apparently, that "Argentine" possesses. I rather failed to understand the exact nature of "Argentine's" difficulty set forth in query 97353; but assuredly reply 97353 (*loc. cit.*) will not help him. I should be very very sorry to say or do anything discouraging to anyone so obviously anxious to enlighten his brother-readers as is "Regent's Park," posing, as he does, as a perfect Admirable Crichton in these columns, prepared to answer questions on every single branch of human knowledge; but even he is not infallible. Why, yet another illustration of this occurs on the very same page, where (in reply 97348) he refers your querist to a perfectly ridiculous book, before spending any money upon which that querist should read No. 370 of the *Edinburgh Review*, for October, 1894. *Ne sutor ultra crepidam.*

I am afraid that "F. B." (query 97393, p. 501) will fail to obtain a new 3in. achromatic (worth anything), equatorially mounted, for £16, and I certainly know of no optician of repute from whom such an instrument, so mounted, whether it be called a "student's" telescope or not, could be obtained at that price. Your querist might pick such a thing up secondhand; but if he saw one advertised, it would be necessary to have it inspected and tested by some competent friend. Besides, instruments are bought by dealers at about the value of the brass and glass of which they are made, and reappear in their catalogues at most astonishingly advanced prices.

"New Moon" (query 97394, p. 501) will find that the last time there was no New Moon in February was in 1893. Your correspondent must employ a professional computer to ascertain in the February of what year this will recur. There was no Full Moon in February, 1889.

The report of the Superintendent of the United States Naval Observatory for 1899 is very interesting reading for all who are concerned in the use and adjustment of astronomical instruments, giving, as it does, a précis of what has been accomplished in this way at Washington with the 26in. and 12in. equatorial refractors, the 9·14in. and the 6·0in. (steel) transit circles, the prime vertical transit instrument, the 5in. (steel) altazimuth instrument, and the 40ft. heliograph, together with some account of the work performed, and a mass of miscellaneous information. The work done with the 26in. telescope has consisted chiefly of measures of the observed diameters of Mercury and Venus in all parts of their orbits, for the determination of the effect of irradiation upon such diameters. In the event, as might *à priori* have been expected, irradiation was diminished by the use of high powers, which, of course, reduced the brightness of the images. The results for unit distance, so far as Venus was concerned, were to make her mean diameter 17·38". It will probably be remembered that Prof. Barnard's determination of this quantity amounted to 17·307", a not very unsatisfactory agreement. Observations with this same telescope were also made of Saturn's satellites, of the famous planetoid Eros, of the *comes* to Sirius, and, by the aid of spectrum photography, of the motion of various stars in the line of sight. The 12in. telescope appears to have been used in the observation of certain planetoids and comets, and of occultations of stars by the moon. It would seem that the public are admitted every Thursday evening to view various celestial objects through this instru-

ment, under the direction of four of the official computers. The 9·14in. transit circle had to be dismounted for alterations and repairs during a portion of the twelve months covered by the report, and the whole observing force was transferred to the 6·0in. (steel) transit circle. Nevertheless, 3,138 observations were secured with the larger instrument. The prime vertical instrument in conjunction with the 5in. altazimuth has been used to determine variations of latitude and the constants of nutation and aberration. The method employed to ascertain the former quantity is as simple as it is ingenious. Using the altazimuth as a vertical circle to observe the declination of α Cygni at every possible culmination both by day and night (that star culminating 5° 59′ north of the zenith at Washington), and that of Vega (which souths 14′ south of the zenith), it is quite evident that the zenith lies between the two stars, and while the changes in the half sum of their declinations will be the variation in latitude, the differences of their declinations should be constant. It is believed that the declinations of stars are observable with distinctly greater accuracy with this 5·0in. (steel) altazimuth when used as a vertical circle than when a transit circle is employed. The 40ft. heliograph is employed to take a daily photograph of the sun whenever the sky is clear. From the part of the Report devoted to the American Ephemeris we learn that in the forthcoming volume for 1903, Newcomb's Tables of the Sun, Mercury, and Venus, and Dr. G. W. Hill's Tables of Jupiter and Saturn will be employed in lieu of those in use in former years. As a detail, I may mention that the apparent semi-diameter of the sun to be adopted will be 961·50″, that now in use being 960·78″. It is probably known to everyone who will read these lines that the value employed in our own *Nautical Almanac* is 961·18″. The gravitational astronomer, no less than the observer, will be glad to hear that the elements of the satellites of the outer planets of our system are undergoing a thorough—and much needed—revision at the hands of Prof. Harkness. I have only touched upon the leading points of interest in the report lying before me, but it will be found well worth reading in its entirety.

In connection with Mr. Bennett's interesting letter (43218) on p. 510, let me assure him that my sole claim was to be *historically* correct. For good or evil, the first year of the Christian Era was called 1 A.D., and, that being so, the century could not terminate until the expiration of the year A.D. 100. As your correspondent will see from my answer to Mr. Watson above, when we come to reckon the number of sequent days which have elapsed between two dates, one B.C. and the other A.D., we have to introduce an imaginary year 0.

I should hardly go as far as "Silverplume" (letter 43219, p. 510) in asserting categorically that 31 M. Andromedæ is stellar. It has a continuous spectrum, it is true; but if it be actually stellar in the ordinarily accepted sense of that word, it is very odd and remarkable that it has never shown any real signs of resolution in the gigantic telescopes now in use in America and in this country. Let us wait and see if the stupendous instrument which is to be a centre of attraction in the Grande Exposition, now so imminent in Paris, will resolve it into its component stars?

If "A. B. M." (letter 43221, p. 511) imagines that I could, or would, shut my eyes to anything in the shape of *evidence* of the influence of the moon on the weather, he seriously misjudges me; but so far we have been favoured with nothing whatever but assertion, pure and simple, of, I may perhaps add, a more or less blatant character. There lies before me the continuous record for 44 years of the weather at a single English station, and a series of the *Nautical Almanac* for 43 of them, containing, I need scarcely say, the fullest details as to the so-called "changes" of the Moon, her Right Ascension, and (what I believe the weather-mongers consider very important), her Declination for every single hour of the period covered, and I defy "A. B. M.," or anybody else, Frenchman, Swede, or American, honestly to trace the slightest connection between them and the heat, drought, lightning, rain, snow, cold, or any single meteorological phenomenon observed during the period to which they jointly refer. It is not difficult to see how a very slender case can be made out for lunar influence on the weather. Varied as it is, there is bound to be *some* place on the surface of the earth in which correspondence takes place between a given position of the moon and the local weather, and this is triumphantly pointed to; while, on the next recurrence of the occupation by our satellite of a similar position, when no such correspondence whatever is traceable between it and the atmospheric conditions in the same locality, some totally different station is picked out, as an illustrative example of the prophet's acumen. This may be very clever, but it is suspiciously like Old Bailey advocacy. *If* the moon does influence the weather, *cæteris paribus*, and under similar conditions, that influence should produce approximately identical results in the same locality; and I say, unhesitatingly, that it does *not*.

I may perhaps say, in reply to the question with which "A. S. L." concludes letter 43222 on p. 511, that to eliminate aberration as far as may be, no achromatic refractor should have a focal length shorter than from 14 to 15 (say 14·5) times its aperture. Of course increase of focal length decreases aberration, but at the same time makes the instrument unwieldy; so that the proportion I have indicated will, I think, be found to be that adopted by our best makers.

The evidence given at the trial of John Elliot to prove his insanity, to which Mr. Monck refers (in letter 43243) on p. 517, reminds me that a dear friend of mine, now dead and gone, used to keep batrachia and reptiles as pets, and that a young lady who knew him, happening to meet the rector of a West of England parish of the same name, inquired of him if he was related to her (and my) friend; to which the response was: "Well, he is a cousin of mine, but"—touching his own forehead—"I do not think he is quite right in his head; he keeps toads and frogs!"

The star of which Mr. Batley speaks (in query 97432, p. 522) is 251 Ceti (Σ 147). The components are of the 5·5 and 7·5 magnitudes, and about 4″ apart. It is not easy to understand why Webb omitted this object.

Probably "Arcturus" will answer query 97434 (p. 522) in detail; but I may just say that, of course, the sine of an angle = the sine of its supplement—i.e., log. sin. 101° 14′ 3″ = log. sin. 78° 45′ 57″, and this is its value *passim*. "Fleur-de-Lys" might study pp. 393 to 420 of Chauvenet's "Spherical and Practical Astronomy" with advantage.

If "W. G. T." (query 97437, p. 522) does bring his telescope into the house, he can expose the object-glass to the fire, of course, at a safe distance, and the moisture will evaporate. The less an object-glass is wiped the better.

In answer to "Polaris" (query 97442, p. 522), I may say that (1) "theoretical limit of power" means *separating*, not magnifying, power, and is obtained by dividing 4·56″ by the aperture of the telescope—e.g., a telescope of 1in. aperture will just divide two stars of the sixth magnitude that are 4·56″ apart; or supposing that the telescope aperture were 2·5in., then would it divorce a pair 1·82″ from each other, while a 4in. object-glass would show as stars just separated a pair 1·14″ apart, and so on. The 100 to the inch refers to magnifying power, and is a practical and not a theoretical limit at all. In fact, though, it is but rarely that such a power can be used in England with advantage. (2) The focal length of a lens equivalent to a Huyghenian eyepiece is found by dividing twice the product of the focal lengths of its component lenses by their sum. Thus in the best form of Huyghenian eyepiece if the focus of the eye-lens be = 1, that of the field-lens will be 3. Call these inches. Then $\frac{2 \times 3 \times 1}{4} = 1\frac{1}{2}$in. (3) When it is stated that the field of view decreases as the power increases, it means that the angular subtense of the stop decreases. In other words, if with a power of 70 the sun *just* fills the field of view, with one of 140 only half his diameter would do so. (4) Look through the list of members of the B. A. A. and get some friend to nominate you. He will doubtless secure you a seconder. The entrance fee is five shillings, and the annual subscription half a guinea. For this you get some fifteen shillings' or a pound's worth of publications annually, can attend the very interesting meetings held at Sion College on the last Wednesday in every month, and can join one or more of the observing sections, whose competent directors prescribe a settled plan of work for the members. You will be puzzled to obtain such a ten-and-sixpenny-worth anywhere else. I have said nothing, moreover, of the excellent lending library, &c. Address Mr. T. Frid Maunder, 26, Martin's-lane, Cannon-street, London, E.C., for all particulars.

If "H. B." (query 97461, p. 523) will give me his latitude, the name of the star to be found in *Whitaker*, and its hour-angle from the meridian, I shall be very glad to repeat the calculation for him for which he asks.

A Fellow of the Royal Astronomical Society.

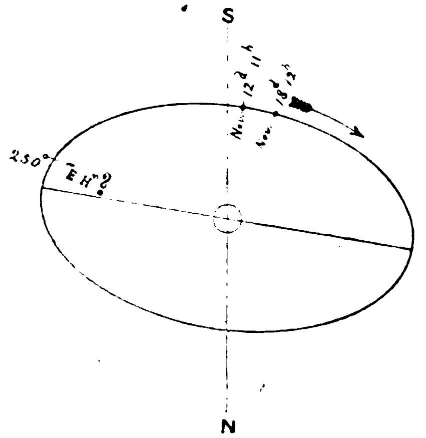
THE SATELLITE OF NEPTUNE.

[43245.]—"NEPTUNE" says in his letter in your last issue (43190): "Can any of your readers give the positions of the satellite of Neptune on the nights of Nov. 12 and Nov. 18 last, when 'Ell Hay' estimated the position-angle as 250°?" I give the graphic sketch shown above, accompanied by a few explanatory remarks.

The ellipse is copied, as accurately as circumstances permit, from the one given in the *Nautical Almanac* for last year, the proportions being preserved, not the size. Upon the curve I indicate the positions of the satellite as computed for the given dates, from data found in that ephemeris, and across the curve I draw a line from which "position-angle" is measured, which is done, as we all know, from N. in the direction reverse to the arrow. The arrow shows the direction of the satellite's motion, and the central circle indicates the planet. The degrees upon the curve were measured off to mark the two positions in question, in their elliptical equivalents, and the measurements were made from the western and eastern apsides.

The position given in (43168) viz., 250° of position-angle is also shown in its place as illustrating the alleged observation by "Ell Hay."

The satellite came to its greatest western elongation on Nov. 11, at 0·3h., and had made very nearly one quarter-revolution by the 12th at 11 p.m., having passed over 88·5°. By Nov. 18, at 12h., it had made one entire revolution and a small part



more, moving, as mentioned above, in the direction of the arrow. It would have come to its greatest eastern elongation on the 19th at 19.9h., and as 12h. on the 18th was short of this by 31·9 hours, its position was 81·4° short of the eastern apsis on Nov. 18 at midnight, which was the reputed time of "Ell Hay's" second observation. The positions of the satellite as measured in degrees from the apsides (the degrees being taken in values dependent upon the obliquity of its orbit as seen from the earth) are marked off upon the ellipse for both dates, but to neither of these positions does the observed one of "Ell Hay" at all correspond.

His position-angle (250°) was given, as he says, with "no great accuracy"; but I think no one can possibly associate it with the true position for either of the dates, for the difference amounts to about a whole quadrant.

I find, however, a small star somewhat near the possible place of his "satellite" when Neptune occupied the place it did at the mean of the dates mentioned, although even that star does not quite suit his observation.

H.

---

15 CEPHEI—A DOUBLE STAR IN CETUS NOT IN WEBB—O Σ 24—63 CYGNI.

[43246.]—"A MEMBER OF THE B.A.A." (letter 42990) must kindly pardon the delay in answering his query; but an accident occurred to my dome, and I was unable to get the telescope on 15 Cephei till the other night. The angle should be 300° instead of 200°. The second query I could not answer, as I do not possess the work in question.

In answer to Mr. Batley (query 97432), the star is χ^1 Ceti. In Lord Lindsay's summary of Struve it is given as follows:—Σ 147 χ^1 Ceti. R.A. 1h. 33·5m. Dec. S − 11° 55′ (1875) P. 88·2°; D. 4″; mags. 5·3, 6·9. Later observations do not show any substantial change. The star has curiously escaped insertion in each edition of "Celestial Objects." I have made a note of it.

The star O Σ 24 R.A. 1h. 4·7m. N. 50° 28′ is described by O Σ as follows:—

A B	66·3°	60·6″	7·0, 8·8
B C	45·4	8·1	C. 11·2

Dembowski, in measuring, added another star: D, 287·9°, 43·8″, mag. 10·5. I found, on Nov. 23 last, a faint companion to this, which thus turns the group into a bright star, with two pairs in the field. The following give my results:—

A B (O Σ 2·4)	.. 65·9°	.. 60·5″	.. 7·5, 10·5
B C ,,	.. 48·7°	.. 8·6″	.. 10·5, 12·5
A D (Dembowski)	.. 286·1°	.. 43·8″	.. 7·5, 11
D E (Es)	.. 82·0°	.. 10·0″	.. 11, 13.

63 Cygni, R.A. 21h. 3·1m., Decl. 47° 15′.—On Dec. 1 I noticed a minute attendant to this star, which I have tried to measure, but have not, so far, been able to deal with it satisfactorily with my rough apparatus. I give below the results for what they are worth:—

Dec. 1	.. P 150·1°	.. D 15·7″	.. Mags. 4·5, 13·5
Dec. 27	.. ,, 153·9°	.. ,, 15·1″	

T. E. Espin.

Tow Law, R.S.O., Co. Durham, Jan. 19.

SCHAEBERLE ABERRATION.

[43247.]—The most complete mathematical exposition of this is to be found in a paper by Prof. C. L. Poor in the *Astrophysical Journal* for 1898, pp. 114-123, and as some of your readers may not commonly see this periodical, a short abstract may be of interest. Lack of space prevents me from giving more than the author's conclusions; for the proofs of these the original paper must be consulted.

Prof. Poor, examining the optical properties of a paraboloid mirror cut from any portion of the curve, shows first that the "field" is spherical, the diameter of the sphere being equal to the focal length of the mirror. This portion of his paper I omit.

In any portion of this spherical field, the aberration (= Schaeberle error) is given by the equation—

$$(14)\quad \tan.\,\gamma = \frac{\sin.\,\alpha\,\tan.\,\frac{1}{2}\theta\,\tan.\,\theta}{2\,(\cos.\,\alpha + \cos.\,[\alpha+\beta])\cos.^2\frac{1}{2}(\beta+\theta)}\,.\,P,$$

where γ = angle subtended by transverse linear aberration at centre of mirror,
α = angle of incident ray with axis of paraboloid,
θ = half angular aperture of mirror,
β = angular distance of centre of mirror from axis of paraboloid.

"If in this expression we put α equal to zero, then we have at once γ equal to zero—that is, the image of a star in the direction of the axis of figure is a point. And this is true for a mirror cut from any portion of the paraboloid: it is the well-known property of the parabola."

Considering the particular case where $\beta = 0$—that is, when the centre of the mirror is at the axis of the paraboloid, as is commonly the case, the equation (14) becomes—

$$\tan.\,\gamma = \tan.\,\alpha\,\tan.\,\theta\,\tan.\,\tfrac{1}{2}\theta\left[1+\frac{1}{2\cos.^2\frac{1}{2}\theta}\right]$$

"A very convenient and dual approximation" to this latter formula may be made by putting—

$$\cos.\,\theta = \cos.\,\tfrac{1}{2}\theta = 1,$$

and the equation becomes—

$$\gamma = \frac{3}{4}\cdot\frac{a^2}{f^2}\cdot(\alpha'')$$

a being the half-linear aperture of the mirror, and α' the angle of incident ray with the axis of the paraboloid expressed in seconds. "The size of the star disc is thus directly proportional to its angular distance from the centre of the field and to the square of the proportions of the telescope (aperture divided by focal length)."

Prof. Poor gives a table (i) showing the actual amount of this aberration for different mirrors, which may be summarised thus—

Aperture: Focal Length.	Aberration for 5′	30′	Star disc, 1° from centre.
$\frac{1}{5}$	2·16″	12·95′	33·3″
$\frac{1}{10}$	·55″	3·30′	9·8″
$\frac{1}{20}$	·14″	·84′	3·2″

The second and third columns giving the distance from the centre of the field in minutes: the fourth column combining the aberration with curvature of field. This we may at present neglect. He remarks: "As a result of this we see that in order to obtain satisfactory results the proportions of mirrors should be about the same as those of lenses: the ratio of aperture to focal length should be 1 to 15 or 20. Good results cannot be obtained with the mirrors now in use—i.e., those in which the ratio is 1 to 7 or 8."

Prof. Poor tested the accuracy of his results by measuring the star-discs in one of Dr. Roberts's photographs of the nebula in Orion, as follows:—

Distance from centre of field.	Measured increase in star image.	Computed aberration.
12′	6″	6″
27	9	12
34	13	15
42	19	19

which is a tolerably close approximation, all things considered.

This letter has already reached an inordinate length, but I hope I may be pardoned for this in view of the fact that papers like Prof. Poor's, where the figures are derived from mathematical calculation, and not from mere guesswork, are unfortunately, not common. **Alpha Ursae.**

MOON'S PATH—DETERIORATION OF ALMANACS.

[43248.]—With reference to the last paragraph of letter 43220, p. 511, I should like to point out that "M. O." is in error when he describes the moon's path in space as "a sort of elongate S, or slightly wavy from a straight line," and that his diagram, being, as he himself admits, greatly out of proportion, gives a totally wrong idea of the moon's path [illegible] to the sun. A reference to p. 233 of Godfray's "Treatise on Astronomy" will furnish "M. O." with a simple mathematical proof that the moon's path is concave to the sun at the very place where he has shown it on his diagram as convex—viz., at New Moon. Diagrams illustrating the concavity of the moon's path to the sun will be found in the work referred to, and also in Young's "General Astronomy," p. 161

Letter 43233 on p. 514 reminds me of a query inserted in the "E.M." for some date towards the end of Dec., 1896, and which seems, by the style of writing, to have been written by the same person. After deploring the deterioration of almanacs (from the querist's point of view), the writer went on to say that it seemed to him a pity there was now no diagrams of the moon's passage through the earth's shadow. In response to his query, I made a diagram of the lunar eclipse on Jan. 7, 1897, which the Editor kindly inserted, but I made no remark about the supposed deterioration. It will thus be seen that, assuming the writer of the letter and of the query were one and the same person, the deterioration of almanacs, from the writer's point of view, lies in their not containing diagrams of lunar eclipses and particulars of solar eclipses for "30 or 40 places in Great Britain, also for Paris." Now it seems to me, from the amateur's standpoint, these details are not very important. Moreover, the *Nautical Almanac* for the current year gives a diagram of the track of the moon's shadow during the solar eclipse on May 28, particulars of the eclipse for six representative places in the British Isles, and the data and formulæ for computing the circumstances of the eclipse for any place. **S. B. G.**

THE MOON'S ORBIT.

[43249.]—On p. 511 of your last issue is a diagram which is likely to mislead your readers. Your correspondent "M. O." may be surprised to learn that *the lunar orbit is everywhere concave to the sun.* His idea of an "elongated S or wavy line" is therefore quite fallacious. If he will plot out the orbits of earth and moon approximately to scale, he will easily see that the above statement is probably true; but a knowledge of gravitational lunar theory (*pace* Mr. Hugh Alexander) is necessary for its exact proof. **C. P.**

HUYGHENIAN EYEPIECE DIAPHRAGMS: RULES FOR—TO MR. E. P. CLARK.

[43250.]—In letter 43104, Dec. 8, your ingenious and persevering correspondent mentioned above made inquiries concerning this subject, complaining that he "can find no rule for the diaphragm," and appealing for directions to the numerous "competent authorities" to be found amongst your readers. To this request there appears to have come as yet no response. My own delay in answering has been largely from a wish on my part to allow the desired information to come from some of the "competents," although Mr. Clark's courtesy has led him to suggest that I also might be able to meet his wishes. But contributing also in no small degree to my delay was the fact that, without a considerable amount of technical circumlocution—call it attempted demonstration of principles—I could not see my way to give the desired information in the form of a "rule," although for fairly good practical indications I could possibly at once have sent short and easy directions for a special case. I felt that such a reply as men of Mr. Clark's stamp demand—i.e., one which embodies all the conditions necessary for any possible case, given in accurate form, and with at least some small amount of accompanying demonstration, that such a reply, even with the assistance of diagrams, might fill more space than should be desirable, and that at a time when we were beginning to have again many interesting communications on subjects which we all delight to see in prominent place—I mean the purely mechanical.

For those amateur opticians, however, who may merely wish to be able to fix up in a sort of good-enough kind of way the mechanical parts of a Huyghenian eyepiece of the most common type, and without any special adaptation to any particular kind or focus of telescope, the following preliminary pieces of information (scarcely to be called "rules") may be given before the general question is entered upon with any pretence to complete accuracy or to to reasonable explanation of the "why and the wherefore."

For this prefatory purpose, let the conditions be: the lens focal lengths as 3 to 1, the lens distance apart equal to half the sum of their focal distances, and the lens apertures of any size which experience has determined for them, or which may be found upon the lenses purchased by those who cannot make them. (Here, the expert will notice, there is no attempt to adjust the distance apart to principal focus of object-glass or speculum.) And, further, it is to be assumed (of course, quite gratuitously) that the actual width of the image formed by the object-glass is equal in width to the aperture of the field-lens, which means that the pencils of convergent rays passing to above image are comprised in a parallel beam, the latter circumstance being pretty nearly the case with telescopes of long focus, whether simple or compound. For example, in the compound reflector, and in the refractor with a "Barlow lens," the pencils of convergent rays about to enter the field-lens of the Huyghenian eyepiece are very nearly parallel, owing to the relatively long equivalent focus; the same, of course, with a very long-focus object-glass or mirror. As showing an approach to this easy assumption (parallelism of pencils, *not rays*, near the field-lens), the figure I gave for a Gregorian eyepiece at p. 578, August 11, and which the Editor has kindly had reprinted, will serve to show the reasons at least approximately for the following simple attempt at a "rule" for the diaphragm. But as the pencils to the right of the field-lens B in Fig. I, although nearly parallel, are not really so, the "rule" cannot be quite correct, and with shorter principal or equivalent focus of object-glass or speculum, the "rule" will be still further from strict accuracy, although possibly near enough for the practice of most amateurs.

In Fig. 1, while the lenses are of relative foci, $2\frac{1}{4}$ to 1, instead of 3 to 1, and of apertures very much greater than what is required for average refractor eyepieces; the geometrical foundation of the reasoning leading to the rule for the diaphragm, is the same in principle as if the present simple assumed conditions just given had existed. Were the beam of convergent rays entering B really parallel, the image at Y Y′ would equal the lens B in width. Now, the available width of B, the field-lens being a fixed quantity, i.e., by either experience of best aperture for given focus, or by "chance" let us say, and, from above assumption of parallelism, the known equal width of Y Y′ enables us at once to find Z Z′, which as the corresponding width of the reduced image formed of Y Y′ by the field-lens B, gives us the diameter of the diaphragm opening. Plainly and without explanation Z Z′ is, under our present assumptions, two-thirds of Y Y′, and as Y Y′, as we have just seen under the same assumptions, equals the useful transmitting aperture of the field-lens, *the diaphragm opening comes to be two-thirds of the aperture of the field-lens.*

This "rule," if it may be so called, is only true under the above assumption—viz., foci of lenses 3 to 1, distance apart equal to half sum, &c., and as these are not the conditions of Fig. 1, Z Z′ does not there equal $\frac{2\,Y\,Y'}{3}$, as measurement will show.

Graphically, the proof of our geometrical assumption is easy enough, for upon drawing Y Y′ = available aperture of lens B, placing Y Y′ at a distance from B equal to $1\frac{1}{2}$ times the distance of the diaphragm from it (the diaphragm being in all such cases as that of our assumed instance, midway between the lenses), and joining the centre of B with the margins of Y Y′ we find that where these lines pass the plane of Z Z′, they define the limits of that aperture. The most elementary knowledge suffices to convince one, without drawing and measuring, that, as the distance of Y Y′ from B is $1\frac{1}{2}$ times the distance of Z Z′ from B, the latter aperture must be two-thirds of that of Y Y′. The proof of the above-mentioned "$1\frac{1}{2}$ times" and other matters can now follow, for the use of those wishing to work out the fundamental principles, so as to be able to apply them to *any* eye-piece, and without limitations, such as those which have led to the above simple makeshift rule just given.

For this, the second part of my humble essay, and in which a certain show of proofs is a necessity, I must, however, assume a previous knowledge on the reader's part of several well-known general principles and modes of representing them: the complete elucidation of the whole *ab initio* would, even in much more ample space, be an absurd attempt.

For facility of reference, I shall number the several steps to be followed.

1. Ascertain the principal focus of object-glass or mirror (or, if compound, the equivalent focus), and $\frac{F}{P} = eq.f.$, where F = principal focus, P = the "power" desired, and $eq.f.$ = the focus of a single lens equal to the effect of the eyepiece combination.

2. Next, determine what relative foci the eyepiece lenses shall have, for, as is well-known, the 3 to 1 proportion in this is by no means either "necessary or sufficient." For example, the lenses in Fig. 1 are of relative focal lengths, $2\frac{1}{4}$ to 1, for certain reasons. The most frequently met with proportions in refractor eyepieces are about 3 to 1.

3. Supposing the above settled, we now find the actual focal length of field and eye-lens to give our desired equivalent focus for (1).

For this purpose readers may consult letter 41097, of May 20, 1898, in which I work out the necessary steps by simple algebraic reasoning.

4. Besides, in using the method there shown, we have to remember that for achromatism in the combination we cannot trust to the simple half sum of the foci for the distance apart, which for simplicity is there used, but must use for "d" a number, which, as shown in 42668, August 11,

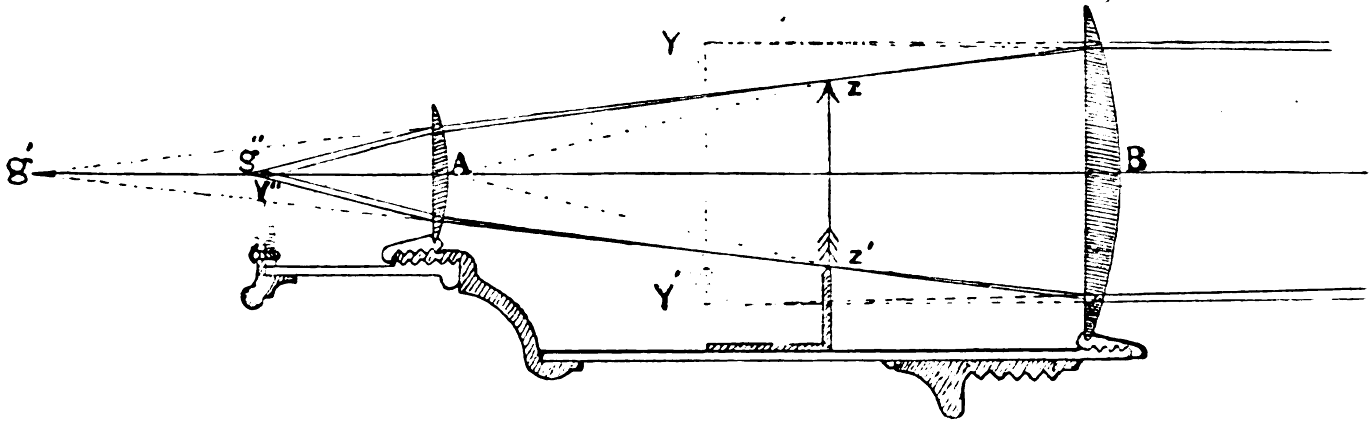


FIG. 1.

depends upon the distance of the object-glass or speculum from the field-lens.

5. Should a certain definite angle of field be not required for some special purpose, then, as already stated in preface, the simple selection of the most appropriate aperture for the necessary lenses leads, along with other procedures, to the resulting aperture

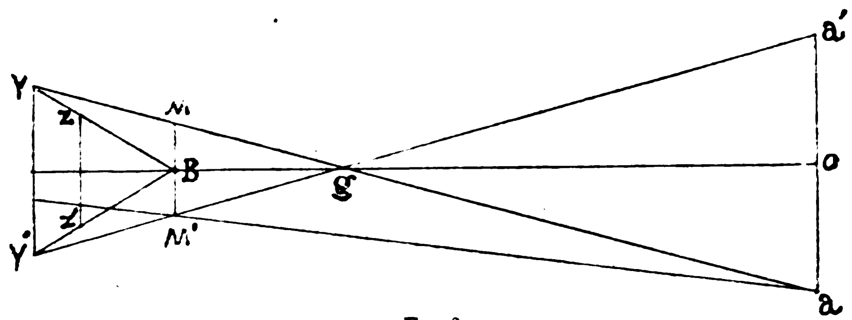

FIG. 2.

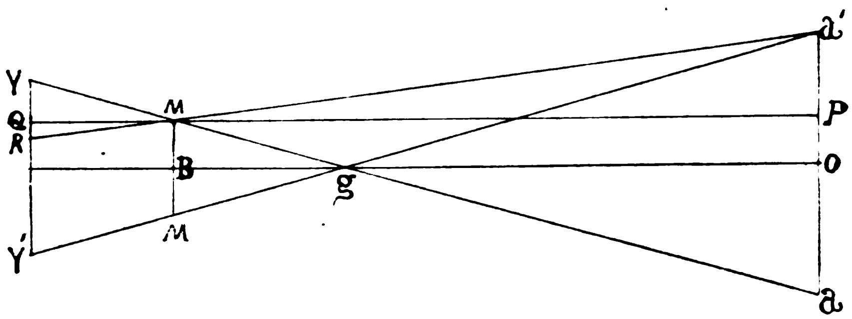

FIG. 3.

of diaphragm, the position of which also is determined by some of the same conditions.

As an example, let our object-glass (or speculum) be of 6ft. focus and 5in. aperture (the o.g. being of the two the better suited to this aperture), and let the power desired be 150 diameters. By (1) $\frac{72}{150}$ = ·48, which = the focus of our equivalent lens. As to (2), let the foci be 3 : 1. The converse of (3) or the equivalent focus of certain lenses of given foci and distance apart, is given, as most amateurs know, by $E = \frac{F \times F^1}{(F + F^1) - d}$, where E is the equivalent focus, F F¹ the foci of the lenses, and d their distance apart. Space prevents the proof of this, which is by no means difficult. Again, we remember a formula, also previously given in these pages several times of late, and which still less permits of exhaustive demonstration here—viz.,

$$d = \frac{F_1 + F_2}{2 - \frac{F_1}{u}}$$

where F_1 is the focal length of the field-lens, F_2 of the eye-lens, and u the distance of the object-glass (or speculum) from the field-lens. (In the compound reflector, u equals equivalent focus minus the distance B Y, or distance of field-lens from secondary focal plane). The refined distance apart given by this means, in order to secure achromatism in the eyepiece, is not used in my simple algebraic deductions from the formula for equivalent focus, as given in 41097, May 20, 1896; neither shall I introduce it here, although to do so would involve no serious complication, as I wish merely to insert here an epitome of the above-mentioned letter for those readers who may not be able to consult it. Therefore (d) in the following is simply $\frac{F + F^1}{2}$, or the half-sum of the focal lengths. To insure correspondence with previous algebraic treatment of the subject, make x = focus of field-lens, and y = focus of eye-lens. Then, as our present conditions give $(d) = \frac{F + F^1}{2}$ the fundamental formula for equivalent focus $\frac{F \times F^1}{(F + F^1) - d} = E$, becomes $\frac{x y}{x + y} = \frac{E}{2}$.

Now, as in the preliminary indications, let us make F : F¹ : : 3 : 1 (other proportions being known to be equally capable of proof as to the present deductions), and as this makes $x = 3y$—

$$\frac{x y}{x + y} = \frac{3 y^2}{4 y} = \frac{E}{2},$$

and by division this becomes—

$$\frac{3 y}{4} = \frac{E}{2},$$

and therefore— $E = \frac{3 y}{2}$.

Our requirements stated above necessitating an equivalent focus of eyepiece, or E equal to ·48in. may now be expressed, therefore, as $\frac{3 y}{4} = \frac{\cdot 48}{2}$, so that $3 y = \frac{1\cdot 92\text{in.}}{2}$ = ·96in., which is the required focal length of our proposed field-lens. For we made $x = 3 y$, and x stood for the focus of the field-lens. From the same, it also follows that our required eye-lens focus (y) is ·32in. We may prove the above arithmetically from—

$$\frac{\cdot 96 \times \cdot 32}{(\cdot 96 + \cdot 32) - \cdot 64} = \cdot 48 = E.$$

The foci being now known, the best practice (for there is no theory) fixes a suitable diameter for the lenses. For example, with F = ·96in., this diameter might probably be made = ·5in., so that B in our diagram (Fig. 1) being made of that measurement, the rest may be worked out (even graphically with fair accuracy).

As before stated, our conditions permit us to make Z Z′, or the diaphragm aperture ⅔ of Y Y′, which, again, our assumptions allowed us to consider equal to the aperture of the field-lens B. Therefore, as the latter has just been found to be ·5in., the diaphragm aperture for our proposed eyepiece becomes ·3in.

For precision, however, we may work out the results numerically from the geometry of Fig. 2. Here all the apertures are enormously increased in order to make the meaning clear. In Fig. 2 (a) represents one extremity of the object-glass (or speculum) diameter, M the margin of the field-lens, and Y that of the image formed by the object-glass unaffected by the eyepiece. A line joining (a), (M), (Y) crosses the axis at (g) and limits the entire possible extent of Y Y′. But to mark off upon Y Y′ the extent of image which receives all possible rays from the object-glass, and is, therefore, fully illuminated, we join $(a$ M′) and produce the line to the plane of Y Y′, upon which it defines a smaller area than did (a) (g) (M). Depending, therefore, upon whether we desire our field of view to be limited to the fully illuminated area, or to include some or all of what opticians call the "ragged edge," we can either graphically or by computation fix upon the required aperture at Z Z′—i.e., at the diaphragm.

Supposing we desire the entire available field, irrespective of equality of light, we must first find the distance B Y and g Y, for o Y and B Z—i.e., the principal focus and the position of the diaphragm are already known (in our case the latter being just halfway between the eyepiece lenses).

Representing the planes Y Y′ and Z Z′ by Y and Z respectively, $\frac{1}{BZ} - \frac{1}{B} = \frac{1}{BY}$, B being the focus of the field lens for parallel rays.

The above in our numbers becomes $\frac{1}{\cdot 32} - \frac{1}{\cdot 96}$ $= \frac{1}{\cdot 48}$, the reciprocal of which is ·48, giving us B Y. To find $(g$ Y) we may now take first the proportion $g o : a a' : : g$B : M M′, and making $x = g o$ and $y = g$ B, we find o B, in Fig 2 to be equal to $x + y$ = F − B Y, i.e., to the object-glass focus minus B Y as found above, and equal to 71·52. We had $a a'$ = 5in., and M M′ = ·5in. Therefore—

$$x : 5 : : y : \cdot 5,$$

giving— $\cdot 5 x = 5 y$

and— $x = \frac{5 y}{\cdot 5} = 10$

so that— $x + y = 11 y = 71\cdot 52 = o$B

and hence— $y = 6\cdot 502 = g$ B.

Again $(g$ Y) is simply $(g$ B) + (B Y) = 6·502 + ·48 = 6 982 and g B : M M′ : : g Y : Y Y′, which in our numbers is 6·502 : ·5 : : 6 982 : ·5369 = Y Y′, from which we readily find the corresponding Z Z′ or diaphragm aperture to be ·3579, as our conditions make Z Z′ two-thirds of Y Y′. Any other proportions of Z Z′ to Y Y′ are equally easy of proof in this way.

Supposing we desire only the field of full illumination which must have a diaphragm aperture smaller than the above Z Z′, let us examine the geometry of Fig. 3, where through the margin of the field-lens is drawn a line, P M, parallel to the axis, and produced to cut the line Y Y′. By similar triangles we find that

$$MP : a'P : : MQ : QR.$$

Now M P is the principal focus minus the distance from that focal plane of the field lens, the latter

distance being M Q of Fig. 3, or B Y of the previous demonstrations, and $a'P = \frac{a a'}{2} - \frac{M M'}{2}$, from which in our numbers we have

$$71 \cdot 52 : 2 \cdot 25 :: \cdot 48 : \cdot 0151 = QR.$$

Then twice Q R, or ·0302, taken from that part of the primary image (the secondary image in the compound reflector) which is limited by the parallel lines drawn through the margins of the field lens, gives the extent of primary image illuminated by the whole area of the object-glass. Our numbers give ·5 — ·0302 = ·4698 for diameter of fully-illuminated primary image, and under our conditions of eye-piece lens proportions, as already stated (3 : 1), the aperture of diaphragm, or Z Z' corresponding to this, is two-thirds of ·4698 or ·3132, a number somewhat less than that found necessary for the case assumed in the introduction, where the field-lens was supposed to receive a parallel beam, in which case Z Z' was found to be ·3.

Or otherwise, we may find the same results from taking into account the value of Y Y', which, as already shown, can be found by using the node g. By similar triangles also (M $a a'$ and M R Y) we have M P : $a a'$: : M Q : R Y, giving in our numbers 71·52 : 5 : : ·48 : ·03355 and Y Y' − 2 R Y = ·5369 − ·0671 = ·4698, the same value found for the fully illuminated primary image by previous method, and consequently ·3132 is again our value for Z Z'.

For other proportions of lens foci than the 3 : 1 used above, and for "(d)" altered to secure a more perfect achromatism, the correct apertures may be found with equal facility, although the proportions more commonly met with have been used in this demonstration. In this way the correct aperture of diaphragm may be found without resorting to rule-of-thumb methods or laborious trials by experiment. Some, however, prefer a practical field, especially for low powers, which is a compromise between the fully-illuminated one just demonstrated and one with dull margins; hence, under these circumstances, the first-mentioned rule comes still nearer what is required. Cooke and all good makers consider the e.p. as part of each telescope, and non-transferable under perfect action.

Note.—Fig. 1 is correct to scale for the lenses shown; Figs. 2 and 3 are mere diagrams, in which all the apertures are much increased. The "field" shown in Fig. 1 is for full illumination, similar to that mentioned in the description of Fig. 3. H.

ADJUSTMENT OF MIRROR AND FLAT OF REFLECTOR.

[43251.]—On account of the interest taken in the reflecting telescope, I send you the following method for the "Final Adjustment of the Mirror and Flat of a Reflecting Telescope," for what it may be worth.

In order to obtain the best results from a reflecting telescope it is essential that the mirror should be absolutely at right angles to the tube, that the flat should be in the central line, or axis, of the tube, and that the surface of the flat should form an angle of 45° with both the mirror and eyepiece. Having approximately accomplished this result by methods often explained in the English Mechanic, I proceed to the final adjustment, as follows:—first, put into the tube which holds the eyepiece, an eyepiece of lower power. Then with a Coddington, or other lens of about ½in. focus, held in front of the eyepiece, in a line with its axis, and about ½in. away, we will see a beautifully clear image of the flat of the speculum, and of the opening of the tube. If these three images are concentric, then the instrument is in adjustment. If they are eccentric, the image will readily show what adjustment of the flat or mirror is required.

I was highly amused to see the remarks of "F.R.A.S." on the Century Question on p. 449, foot of second column, and congratulate him on his change of opinion, for it is evident from his letters in Vol. V., pp. 130 and 206, that he then held a contrary notion as to when the century began. To quote from p. 206, Vol. V., he says: "But I cannot help pointing out the wonderful post against which some of your recent correspondents have run their heads. They seem to conceive that the Christian era began on Jan. 1 in the year 1. It really began on the first day of the year 0. There was no year 1 until this was completed"!

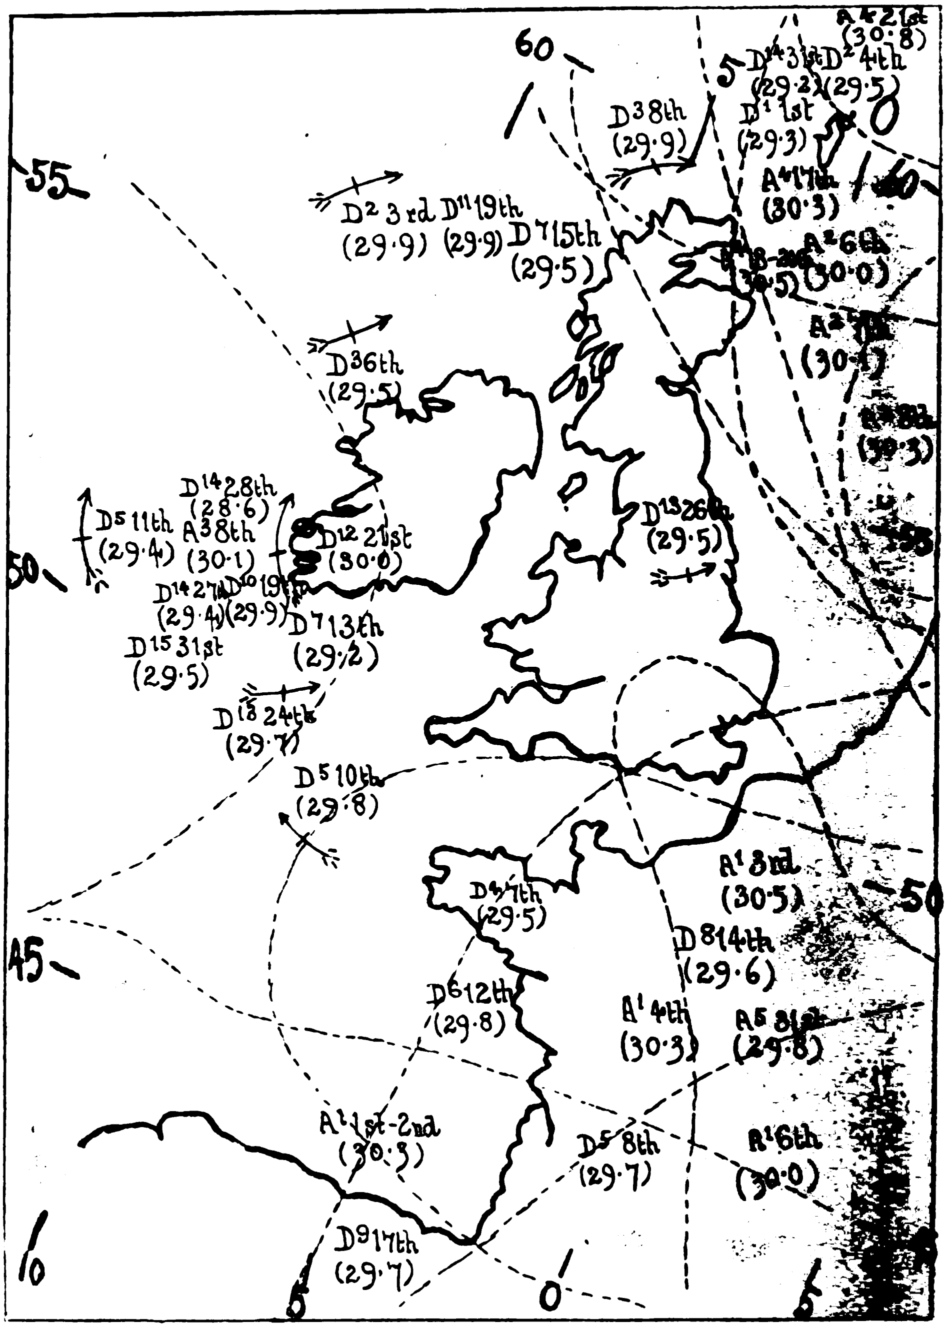
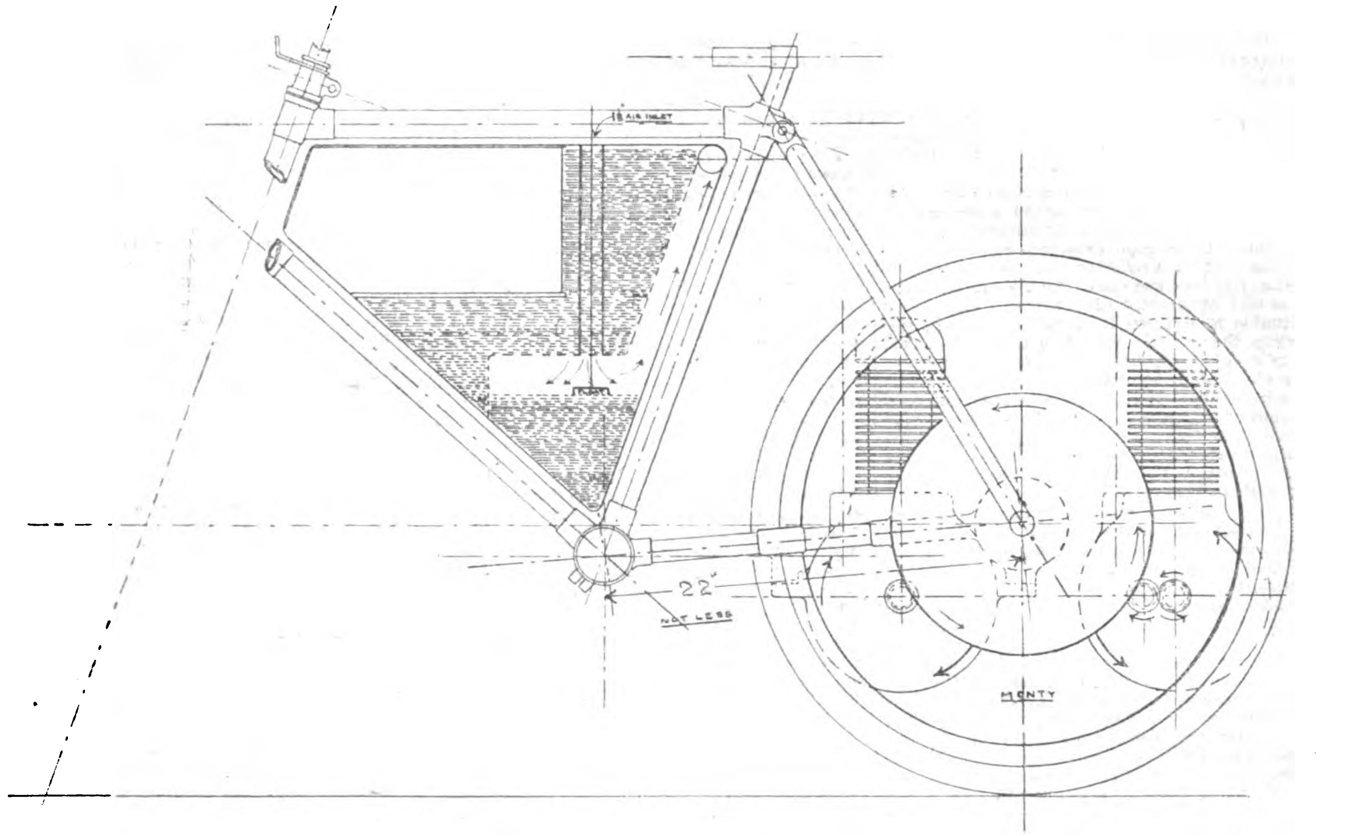
THE WEATHER OF THE BRITISH ISLES IN DECEMBER 1899 — THE RAINFALL OF THE YEAR, 1899 — THE FORTHCOMING TOTAL ECLIPSE OF THE SUN: A QUESTION.

[43252.]—It will be noticed that December produced an anticyclone of unusual intensity on the 21st, when the corrected barometric pressure over the Scandinavian peninsula was as high as 30·8in., whilst on the 28th the abnormally low reading of 28·4in. was registered over our islands.



Date.	Cause.	Effect.
1 to 4	High pressure in the S.E., relatively low in the North.	Fair as a whole in S., but some fog locally. Rain in the N. and N.E.
5, 7	Deep depression over Ireland.	Rain everywhere. E. gales on N.E. coasts.
8	Depression off the Orkneys. Anticyclone over the Baltic. Depression over the S.W. of France. Anticyclone over Ireland.	Fair weather generally throughout our islands. Strong easterly winds on E. and S.E. coasts of England, a N.W. gale at Scilly, light and variable winds elsewhere.
10	Depression off W. of England.	S.E. of Scilly. Fair elsewhere.
11 to 13	Depression off Ireland, and another over the Bay of Biscay, gradually merging into "straight isobars," causing the cold air from the Continent to be drawn in a strong current across our islands.	Strong S.E. winds, fair in the South. Snow and sleet in the E. and N. Northerly gale off the west coast of Ireland. Very low temperatures throughout.
14, 16	Stationary anticyclone in the S.E. Depression in the N.W.	Fog and great cold over E. and S.E. of England. Mild and rainy in Ireland.
17, 18	Depression from the S.W.	Sudden complete break-up of frost.
19	Depression off W. of Scotland. Depression off S.W. of Ireland. Anticyclone over Denmark.	Dull weather in Scotland. Rain in Ireland. Fair, but dull in places, in England.
20, 22	A high-pressure system of great intensity over the Scandinavian peninsula. Depression off S.W. of Ireland.	Dull, gloomy, and showery, with wet fog in places, throughout the entire country.
24, 26	Depression of moderate depth crossing through the central regions of our islands.	Very unsettled and showery, with, however, some bright intervals.
26, 27	Depression central over England, another approaching from W.	Unsettled generally; cold rain, followed by sudden frost, fog, and mist.
28	Unusually deep depression off the S.W. of Ireland.	Rain in England and Ireland. Snow in Scotland.
29, 31	Deep depression off the W. of Norway. Another over Ireland.	Gales of moderate strength, with moderate falls of rain generally throughout the country.

The total rainfall for the year 1899 amounted in this district (East Surrey) to 19·99in.; the wettest month of the year, and at the same time the driest, was November, whose 4·06in. of rain all fell on the first eleven days, leaving the remainder of the month to give us an absolute drought of 19 days.



According to *Whitaker's Almanack*, referring to the total solar eclipse of May 28 next, "the line of central eclipse passes from California across the northern portion of the Gulf of Mexico, and, leaving the east coast of America near Charlestown, crosses the Atlantic." May I ask why I have not seen any mention of an expedition to the United States to observe this phenomenon, as it seems to strike one that that country is in a more healthy condition than either Spain or Portugal? **Meteor.**

FOGS IN FROSTY WEATHER.

[43253.]—THE question was recently put to me, How is it that mist, which is popularly supposed to consist of water particles, with or without dust nuclei, is so often seen when the general temperature is below freezing? Why do these not freeze into solid ice, and fall down?

It is pretty obvious that they must freeze—in fact, that such a fog consists of particles of ice. This suggests a rather pretty sequence of cause and effect. Ice is lighter than water, consequently more buoyant.

Cold air is denser than warmer air; consequently bodies which float in the former (unless contracted by the cold), should do so more readily in the frosty atmosphere.

The lighter ice and the heavier air give the best possible conditions for the permanence of such a fog. **Glatton.**

MOTOR-CAR.

[43254.]—MAY I also as a car owner add a few remarks, in all humility, on the general design of the motor for light car illustrated this week? Before doing so, I should like to say how thoroughly I agree with "Country House" on the points mentioned by him. As to motor. Having settled on employing horizontal valves, for which I can see no reason and which I don't think can be as good as vertical ones, why go out of the way to introduce a quite unnecessary bell-crank lever, with its extra joints and rattle, when it is just as easy (and easier) to drive the valve direct from the cam shaft?

Why also go out of the way to introduce an extra water-joint, seeing what a weak point they always are, when, by casting the combustion-chamber and cylinder breech in one, it may be avoided. By filling up the core holes at the back of the cylinder and connecting the combustion chamber (including valve-jackets, of course) with the cylinder jacket by two small copper pipes, I do not see that any water-joint at all need be used.

Would it not be far simpler to cast cylinder and half the crank chamber in one, the second, or outward, half being bolted thereto with a vertical joint? I fancy it would be easier and practically just as good to build up the crank-shaft, thus saving a forging. Why not inclose reduction gear in crank case, insuring constant lubrication and protection? Of course, I am only referring to the spur-wheel, not the cam.

May I add, in conclusion, that I also am only an amateur?—which, perhaps, may be apparent from the foregoing! **Dragoon.**

[43255.]—A FEW friendly criticisms on the articles describing above from a practical automobilist may not be without interest to your readers, the more so as the car described appears to exist as yet only in design. There seems to be no provision for maintaining rigidity in the front axle with relation to the body, this appearing to depend on the springs alone, which would necessitate their being unnecessarily stout for such a light car. Perch-bars, or some kind of vertical guides, would be preferable, unless semi-elliptical springs were used. I emphatically agree with "Country House" regarding the use of chain steering, having personal knowledge of its liability to failure. There is precedent for it, of course, as there is for most faulty designs in cars. The idea of economising by having a small sprocket is rather amusing, as it means using up a costly pair of chains in much less time. I do not fancy there is any controversy on this point among automobile engineers, and even the difference between a six and eight-tooth pinion is marked—a five-tooth is really too small.

There is much to be said in favour of steel and wood framing, as the wood greatly diminishes the liability of a steel frame to suffer from vibration. Regarding the brake, it is to be hoped that a steel cord going round a pulley does not form part of its design. The Mors car, as constructed till lately, by the way, had a single pedal for brake and disconnection of engine, and was a belt-driven car. Regarding engine design, the writer would not recommend drilling stud-holes through to water jacket if he had had to spend a fine morning endeavouring to extract a broken stud that had rusted in, while his friends on their cars went on without him. It seems a pity, too, that with horizontal valves the bell-crank lever 22 is not dispensed with, and a roller on a straight push-stem arranged to run on half-speed cam, the latter being brought into line with it. The valve springs, with their ends running through valve-rod, seems rather a slipshod arrangement—a key is the best method here. Finally, how is wear to be taken up on small end of piston-rod? **R. W. B.**

MOTOR-TRICYCLES.

[43256.]—THE rough outline sketch shows a method that may be adopted to increase the power on motor vehicles, and at same time lessen the vibration.

To prevent an explosive engine vibrating, it is not only necessary to balance all moving parts, but to counterbalance explosive impulses, it being a well-known law in mechanics that action and reaction are equal and opposite. The tendency of all the makers is toward some form of balanced engine. Many have an idea that by splitting it up into two of three cylinders the object will be gained, whereas nothing of the sort is accomplished.

By the sketch it will be seen that it is simply two ordinary motors coupled one in front of the axle, and the other at the back, the relative positions of the pistons being maintained by the large gear-wheel of tricycle and an intermediate pinion placed between the back motor. It will thus be seen the two motors are running in opposite directions, and the vibrations of the one tend to neutralise the vibrations of the other, more especially that set up by the flywheels, which is greater than that caused by explosions on piston. The engines are geared so that pistons are both at same time at top and bottom of stroke, wheels having gear arranged with even divisible number of teeth, to insure correct timing of pistons. Particular attention must be paid to lightness of moving parts. Pistons, if lightened, are better made in *malleable* iron, or you may blow the bottom out. The flywheels must be balanced either by weights cast in, or holes drilled in rim of sufficient size to balance crank-pin and half the weight of the connecting rod. The cam-gear large spur-wheel may also be balanced with advantage. By a simple arrangement like this, many advantages may be obtained, one being out of date; $1\frac{3}{4}$H.P. engines can be made to give smoother and better running than single $2\frac{1}{4}$H.P.

It is more particularly applicable to racing machines, which makers will soon have to design especially—lighter and more powerful; and it is for these I commend the idea.

I should have mentioned that explosions do not take place on both pistons simultaneously, but alternately, and each then follows through the usual cycle.

Anyone making these small engines can easily couple up a pair on bench to test theory for himself, and by taking off intermediate stud pinion (which by the way, I fear will prove noisy), see the effect of vibration set up by one engine singly, and then when opposed to opposite influences.

Personally, I have found vibration from road far exceed anything set up by engine; even when using larger powered motors; consequently large pneumatic tires are indispensable, 3in. being least size for bad road. These are a costly item on all good cars: hence price of same. A set of three 26in. by 3in. average £5 per wheel, the price being out of all proportion to cost of manufacturing same, even allowing for royalties, &c. **Monty.**

ORIENTATION.

[43257.]—WOULD Mr. Norman Lattey (whose racy rehearsal of "sights" suitable for the delectation of those who use the telescope as an aid to rational amusement I am sure we all enjoy) kindly make it clear to some of us more prosaic users of telescopes what is meant by the following reference to orientation in connection with his pictorial descriptions at p. 505? Here is the puzzle: "(it should be remembered that an astronomical tele-

scope inverts and the north is invariably at the bottom of the picture, though the east and west retain their normal positions)."

Is this to be understood only of the "pictures" which appear in his story—for, from some reason not apparent to the reader, they might have been so drawn—or is it to be understood of the "picture" actually seen in the "astronomical telescope," at least, in an astronomical telescope of the kind which inverts in the usual way?

Now, while the Newtonian reflector (which is not the telescope he uses) may indeed under certain circumstances show an apparent orientation, which may puzzle one a good deal, the simple inverted image as seen in a reflector can scarcely be thus mistaken; at least such has been my experience, as well as that apparently of those who have taken the trouble to mention it in their books. In this inversion, the north is not only where to the naked eye, or to a non-inverting astronomical telescope, the south would be, but the east and west are similarly reversed, and far from having "retained their normal positions," for the "preceding" part of the field, as many observers call it (which as we know is towards the west), appears in the inverting telescope towards the east—i.e., towards the left-hand while looking south.

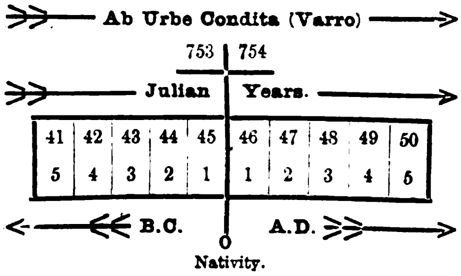
But is it not also somewhat wide of accuracy, even if meant only for the amusement of *dilettanti*, to assure them that "the north is invariably at the bottom of the picture"? No doubt this is so on the meridian, but if much east or west from it (not to speak of circumpolar objects at all), the north comes to be much removed from "the bottom of the picture."

Towards the eastern sky, may not the north appear to occupy that part of the field which corresponds in position to IV or V o'clock on the clock dial, while towards the west may it not appear in the quadrant occupied by VII or VIII o'clock? Therefore, should this be the case, where the east and west line is not only reversed as to its ends, but is, in addition, possibly much tilted, how is the sapient amateur to reconcile matters with the statement that "the east and west retain their normal positions," the north and south only being reversed? With the simple east and west movements of an altazimuth stand the above must be especially hard to grasp. H.

THE TWENTIETH CENTURY.

[43258.]—MAY I, as an old contributor, say something on the curious calendar-strife which the beginning of the 1900th year has revived? Some writers seem not to know what it is that they are writing about; some seem to be incapable of arguing intelligently upon their own data, whether right or wrong. As to "what we are talking about," the following diagram sets out the facts:—

DECADE OF YEARS OF THE JULIAN ERA.



This diagram may need some explanations.

Years *ab urbe conditâ* (A.U.C.) are years counted out from the supposed date of the foundation of the City of Rome. These years are given according to Varro, the greatest authority on that chronology; but the old calendar of the Romans fitted the years like a bad clock fits the time. The calendar was sometimes too fast, sometimes too slow. Not only was the calendar a bad fit for the course of the years, but it was made a football of by political factions, who, being trusted with its occasional correction, sometimes put it on and sometimes put it back, in order to facilitate their electioneering tricks, and with only secondary regard for keeping the calendar in beat with the course of the seasons.

Some forty-seven years before Christ, Julius Cæsar—the then Dictator of Rome, and one of the greatest men of antiquity—the man who did Britain the service of conquering it twice, and introducing to it the Roman language, laws, and civilisation—had his attention called to the vast inconvenience of this state of the Roman calendar, which was then some three months too fast, and indicated the time of spring when the season was really midwinter. He added some ninety days to the calendar for the year 46 B.C., and made that year of the calendar to extend over 445 days, which, in effect, put back the calendar some 90 days. Julius Cæsar then made the year 45 B.C. to commence on the first of January, on the day of a new moon. In order also to make the calendar keep better time, he took up the odd quarter of a day by making every fourth year into what we now call a leap year. This was one of the great services done by Julius Cæsar to the world, and the calendar thus defined with a year of 365 days, but with every fourth year of 366 days, was called the Julian calendar. The seventh month of the year was named Julius, in honour of Julius Cæsar.

The precise length of the real year was not then known; but subsequently the continual revolution of the seasons showed that the Julian calendar was a little too slow. This was because, as we now know, the length of the year is 365¼ days *minus* 11′ 12·43″. Every recurring leap year, therefore, left the Julian calendar nearly 45′ behind time—like a late train (44′ 49·72″). But the Julian year was very nearly the real year, and it was so vast an improvement upon the former calendar that the years from the 1st of January of the first Julian year (45 B.C.) were regarded as the Julian era. Now, the above diagram shows that decade of Julian years which covers the period from the end of the 40th Julian year to the end of the 50th, each year being indicated by a space which represents the interval *in time* covered by that particular year. According to the chronology of Varro, the 45th and 46th years of the Julian era were more or less contemporaneous with the 753rd and 754th years from the foundation of Rome. These years are indicated in the diagram by the two top numbers.

The end of the 45th Julian year was the date adopted by the Monk Dionysius Exiguus in the year A.D. 527 as the commencement of the Christian era. It therefore follows that the 45th Julian year was the first year before the commencement of the Christian era, and that the 46th Julian year was the first year after the commencement of the Christian era. The decade of years of the Julian era from 41 to 50 inclusive was thus contemporaneous with the first five years before Christ (B.C.), and the first five years after Christ (A.D.). If, now, the diagram be considered by the light of this explanation, and the spaces be regarded as representing the respective years, it should be easy to see "what it is that we are talking about."

As to the leap years of the Julian era, Julius Cæsar was assassinated by wretches who wanted to seize Rome, and the putting in of the leap years fell into the hands of the priests. They blundered over it, and for the first 36 years of the Julian calendar they put in a leap year every third year instead of every fourth year. The priests managed this by something like the method of Lord Dundreary, who discovered that whether he had ten fingers on his two hands—or nine, or eleven—depended solely upon whether he counted his fingers forwards or backwards, and where he left off before he summed them up. Whether the priests began, as some sages of this day do, with a zero year, I do not know. But they counted both extremes, as was the custom in Rome, and so made every three years into four. The result was that in the 37th Julian year, the Emperor Cæsar Augustus discovered that the calendar was too slow by three days, and he then ordered that the next three leap years should be omitted. Now the next three leap years would have been 40, 44, and 48 of the Julian era, and these were all reduced to 365 days each. It was not till the fourth leap year, the fifty-second Julian year, and the seventh of the Christian era, that another year of 366 days was let into the calendar. Thus it came about that leap years were non-existent in the Julian calendar at the commencement of the Christian era.

Owing to the Julian calendar, with its leap years, proving too slow for the years by an annual interval of 11′ 12·43″ = 44′ 49·72″, or nearly 45 minutes every leap year, the calendar had got twelve days behind the true season of the year in the time of Pope Gregory. By that time the true length of the year was more accurately known, and Pope Gregory then put the calendar on ten days, so as to correct it for the days it had fallen behind, while, in order to make the calendar in future to keep better time with the revolutions of the earth round the sun, he ordained that all the centurial leap years except such as were divisible by 400, should be left out. This was in 1582. The Julian calendar, thus further corrected, thenceforth was very unfairly called the Gregorian calendar. What the Monk Dionysius Exiguus had done in 527 was simply to steal the Julian Era. Its first 45 years he cut off, and its 46th he called the first of the Christian era. Otherwise it remained the Julian calendar. And all that Pope Gregory had done was to partly make those further corrections in the number of leap years which the Julian calendar in its working for centuries had shown to be necessary. The Catholic countries in general at once adopted the New Style (N.S.) of Pope Gregory. This reformed calendar was ten days in advance of other nations, and the unreformed calendar, for the sake of distinction, had to be denoted as Old Style (O.S.) England, being a Protestant country, did not then adopt Pope Gregory's New Style, nor his omitted leap years. But in 1752 England did this by Act of Parliament (24 Geo. II. c. 23). Russia, being under the sway of the Greek or Eastern church, has even rejected the reformed calendar till this day. Christmas Day, which we held on our Dec. 25, was therefore in Russia the 13th of Dec. Again, owing to the 1900th year with us having its leap year omitted, while in Russia it is still a leap year, as ordained by Julius Cæsar, their calendar will be 13 days behind time on their first of March, 1900. Anglo-Russian documents therefore have to carry two dates in order to avoid confusion. The dates will appear thus:—

Thursday, 1900, March $\frac{15 \text{ O.S.}}{2 \text{ N.S.}}$

Reverting now to our diagram, it will be evident that the years B.C. are merely a retrospective method of labelling time, and that, in counting the years B.C., we count backwards, and in each year we unavoidably begin with the 31st of December, and end with the 1st of January. The years A.D. we count forwards, precisely as we count the years of a man's age, and the early calendar A.D. we regard precisely as we regard the calendar to-day. It is, therefore, evident that the 100th year has to be completed before the 1st century is finished, and that the 1900th year has to be completed before the 19th century is finished. When we come to nineteen hundred *and* one we shall have completed the 19th century and entered upon the first year of the 20th.

As to the sticklers for the precise moment of the real Nativity, we know neither the day nor the month of the Nativity. Historians, moreover, are agreed that Christ must have been born prior to February in the fourth year B.C. But whether Christ were born five years before the date now in use for the commencement of the Christian era, or were born five years after it, or had never been born at all, makes not a particle of difference. Our calendar has been determined by an English Act of Parliament, and it would be alike impracticable and futile for us now to attempt to alter it. Nor does the naming nor dating of our era have anything to do with the number of years which have to be allotted to a century. If a cheque for £100 be misdated, that makes no difference to the number of sovereigns which the payee is entitled to at the bank-counter. So, in order to complete a century, we must finish up its 100th year to the last moment.

James Edmunds.

26, Manchester-square, W.

DOUBLE-ENGINE RUNNING ON RAILWAY.

[43259.]—IT is much to be wished that some of your readers would give attention to the boilers, or, more correctly speaking, the want of boilers on our locomotives. Trains get longer, carriages get heavier, but the new engines won't do more work than the old ones did. The result is that nearly all the heavy fast expresses have to have a second engine or they can't keep time.

What do we see? Two big engines drawing a train that one should draw, and four men being paid to do the work that two should do. There is a fearful waste of locomotive power going on simply because our modern engines have their cylinders too big and their boilers too small. If an engine is to do good work it must have a Large Boiler.

FIELD ARMOUR.

[43260.] — WHILE reading the letters on this (especially present) interesting subject, I am reminded of the famous bullet-proof coat, so much talked of three or four years ago. Can any of "ours" tell me why it was not adopted in our army? I remember reading in a newspaper of the trial before the Duke of Cambridge, where a 9lb. breast plate successfully resisted at close range a rifle ball which a 2ft. oak log could not stop. Surely if our soldiers had been clothed with this remarkable material it would have saved many lives at such battles as Dargai and in the present war, and would be much better than these shields. On looking at the neat sketches of letter 43203, I was struck with the size of the wheels, and they appear to be of iron; if so, they would surely weigh several tons. How are they to be moved about in such a country as the Transvaal by five men? E. R.

[43261.]—THE less must not be held to include the greater: to criticise Mr. Lawler's scheme is not to offer an opinion on the general question of field armour. Thus it is not apropos to quote against me Sir Walter Scott's attitude of mind with regard to the question of gas illumination.

The idea of field armour is an old one; but hitherto practical difficulties have stood in the way of its adoption, even as an experiment. When Mr. Lawler, or some other inventor, can produce a bullet-proof material extremely light and convenient in every way to manipulate, then the pros and cons. of the field-armour question will be the subject of interesting discussion.

Meanwhile it is easy to show that the inventor's schemes (or such of them as I have seen) are, to put it mildly, impracticable, simply because any efficient field-armour would be too heavy for use in the field. By field armour in this connection I mean bullet-proof armour protecting *attacking infantry*,

and intended to secure their *close approach* to the enemy. Now, if you want to protect a man you must do it properly, because a wound disables *pro tem.* (and by hypothesis the protection is only required on an emergency) as effectually as death. A shield 2ft. by 2ft. would do very fairly well if a man kept crawling on his stomach; but I do not think this idea recommends itself. A shield 4ft. high is not good enough, and I think Mr. Lawler (who is evidently in thorough earnest) will, on reflection, admit this. No, a shield must be say 5ft. 6in. high and 2ft. broad as a minimum, and will be 11sq.ft. in area. According to latest experiments, $\frac{3}{16}$in. hardened steel is bullet-proof at forty yards. This is good enough, but unfortunately it weighs about 7½lb. per square foot, and a shield would weigh 80lb. per man. If anyone thinks this a practicable weight let him try and carry an ordinary door in the position in which he would have to carry a shield.

But supposing you were to get each infantry soldier to carry an 80lb. shield over a mile and a half of give-and-take ground to the attack, would our generals in South Africa like to provide the necessary transport? The weight of the shields per battalion would be about 30 tons; to move this would be required 30 carts and 180 mules, or equivalent transport. Though Mr. Lawler is of opinion that "shields would have taken us to Ladysmith long ago," yet he will admit that accidents will happen, and that even with shields Sir R. Buller might have been checked at Colenso. Now, imagine that Buller had shields, that he *was* checked at Colenso, that he retired to Chieveley and Frere (still in possession of his shields), and there waited for reinforcements (with shields), and that he determined on the move which he began on the 10th inst.; as it is, his baggage train we are told extended over 19 miles of road. Under our imaginary circumstances, transport would have been required for an additional 600 tons—that is the equivalent of 600 carts and 3,600 mules. Is that "good enough"? As a matter of fact, although it is sufficient to give the foregoing reasons (the only ones probably which will appeal to "inventors") in support of the proposition that field-armour under present conditions is impracticable, yet the most important reasons are founded upon purely military considerations. With these it is unnecessary to occupy your space; but they are so cogent that even if bullet-proof material were considerably lighter than it is, I believe military opinion would be against its use as field armour. **Sapper.**

USEFUL AND SCIENTIFIC NOTES.

THE Admiralty have ordered a third-class cruiser to be laid down in Devonport dockyard forthwith. She will be 310ft. long, have a speed of 20 knots, and be armed with sixteen quick-firing and two Maxim guns.

THE annual Blue Book relating to canal traffic in the United Kingdom in 1898 has been issued. From this publication it appears that the total mileage of British canals was 3,906, and during the twelve months the traffic conveyed over them amounted to 39,358,394 tons, which earned a total revenue of £2,408,534. Of the total, the share of the Manchester enterprise was 22,118,005 tons. Add to this 6,009,820 tons, the quantity carried by railway-owned canals, and it appears that the other waterways conveyed a little over 11,210,000 tons.

FROM a report recently made by Preece and Cardew on the cost of lighting railway carriages by electricity, it appears that the total annual cost per coach would be £13 16s. 6d., based on the cost of fitting and running 400 coaches with an average of 12 lamps of 8c.p. per coach. The total capital outlay for lighting this number of coaches is estimated at £32,000. These figures somewhat exceed those contained in a report on the subject by Mr. W. Worby Beaumont some months ago, and show that the capital outlay would be about 50 per cent. higher than for compressed oil-gas for equally effective lighting, while the gas would cost about 25 per cent. less for supply and maintenance.—*The Engineer.*

OWING to the growth of the incandescent system of gas lighting in Germany, proposals have been made to reduce greatly the candle-power of the gas provided, with a view to cheapening its production. At Magdeburg, according to the *American Manufacturer*, the question has been seriously debated as to whether it would not be well to reduce the candle-power from fourteen, its present value, to ten, and finally to eight. Experiments show that when used with an incandescent mantle, the poor gas has in certain cases given even more light than the rich. Thus, in one series of tests, a burner of this type was supplied with gas ranging in candle-power from fifteen to two, and the latter actually gave the best light. Probably it contained a considerable amount of hydrogen. With the recent improvements in water-gas manufacture, a gas rich in this constituent can now be very cheaply produced.

REPLIES TO QUERIES.

*** *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[96919.]—**Floating Body in the Air.**—Having noticed the wording of the advertisement of Mr. Maskelyne's trick of retaining the body in the air "without any tangible support," I took the opportunity of being for a few nights in London during the middle of October last to visit the Egyptian Hall at an afternoon performance, having with me a good opera-glass, as is my usual habit. I at first took a seat on the ground floor of the auditorium; but finding my view interfered with from any seat available, I went up into the gallery and managed to obtain a seat in the centre that was unobstructed. The conclusion at which I arrived was that there was a very tangible support indeed, which I admit I could not actually see; but I could, and did, see the actual spot where it was located—viz., on the side of the "floating" man furthest from the audience, at or near to the waist of the "floating" individual, whom I will call the subject, and the gentleman who demonstrated (I presume Mr. Maskelyne), the operator. Covering the back part of the stage there was a daïs, about the height of a table from the front part of the floor. On the daïs the subject laid down on his back. The operator was dressed in a pseudo-Chinese costume, including a flowing silk robe of a moderately light-blue colour, if I remember rightly (the colour not being of any special importance). The operator took a good-sized cloth, much like an ordinary table-cover, and placed it over the subject, entirely concealing him, the cloth hanging down a few inches below the margin of the daïs. He then passed behind the subject, and stood near his waist. Slowly and gradually, without noise, the subject rose until he reached about the lower part of the operator's chest, and the latter then removed the covering from the recumbent man, who then appeared to be floating in the air. The operator then went through various manipulations intended to show the absence of any support, including the passing of a hoop, that had every appearance of being complete, and I believe it was so, over the feet and up as far as the operator could bring his left hand, then back again. Then taking the hoop in his right hand, he passed it over the head of the recumbent figure to a part about one foot or so nearer to the feet than the spot to which he had brought it from the other end. But he did not at any time pass the hoop over the subject from one end to the other completely. And, moreover, I noticed particularly that the hoop, when at its extreme limit from either end, was held obliquely, but in opposite directions, thus, Λ, so that in both cases the part of the hoop next the audience passed a certain spot on the subject, while the part of the hoop away from the audience did not do so. So much for the facts. Now, my conjecture is that while the subject was lying covered, a substantial support was attached at the spot above indicated. The operator stood just behind that spot while the figure rose, and practically concealed the support by a fold of the robe. He may possibly not have actually concealed it, but only rendered it so inconspicuous as not to be noticed by the audience, for the support may have been painted the exact colour of the robe, and even bent into some curve resembling a fold in the robe. I have generally observed in these tricks that something quite unconnected apparently with the object is precisely that on which the *crux* of the whole depends—hence the adoption of the Chinese robe. GAMMA SIGMA.

[97016.]—**Electro-gilding.** — As PC dissolves very readily in water, why not add more water? REGENT'S PARK.

[97032.]—**Ink.**—Dissolve gluten in pyroligneous acid. Soap-like fluid is obtained, which is diluted to strength of ordinary vinegar. To every pint add, lampblack ¼oz., indigo 20gr. Or lampblack 1, potash water-glass (syrupy) 12, aqua ammoniæ 1, distilled water 38. REGENT'S PARK.

[97045.]—**Sanitation Watered Silk Paper.**—If you mean satin paper stains. Grey light: dissolved parchment shavings 8¾oz., water 1¼gallon. Mix pulverised chalk 4¼lb., Frankfort black 8¾oz., Paris blue 1oz., wax soap 3½oz. For glazed paper. Black: glue 1lb., water 1¼gal. (triturate with lampblack previously rubbed up in rye whisky). Frankfort black 2¼lb., Paris blue 2oz., wax soap 1oz., add liquor logwood 1¼lb. REGENT'S PARK.

[97174.]—**Water Power.**—All information of the kind required is to be found in Molesworth's Pocket-book, published by E. and F. N. Spon, 125, Strand, W.C. The calculations necessary to answer the query definitely would occupy more time than I could spare. The fall being only 4¼ft., probably a breast wheel would give the best results; but everything depends on details as to the "best" arrangement. The work above mentioned gives useful information on the subject. METOPS.

[97180.] — **Marine Navigation.** — Thanks to "J. J. H.," but will he tell me in which of the "guides" to marine engineering I can find full information about the exhaust steam from the auxiliaries being used to drive the main engines of a liner? It seems strange that the exhaust steam from auxiliaries should have so much power left in it; but it is easy to understand that it can be used for "evaporating fresh water for the boilers," though it is rather puzzling to know what the boilers do with the evaporated water. However, no doubt "J. H. H." speaks from knowledge, and can refer me to an authority. It seems to be peculiar work to use so much steam in auxiliaries that the exhaust can drive the big engines. Rather wasteful, is it not? G. S. N.

[97212.]—**Molybdenite.**—If you were to write the Secretary, Metals Exchange, London, E.C., I have every reason to believe he could quote approximate prices very seldom mentioned, if at all, in London or market reports. REGENT'S PARK.

[97218.] — **Potash - Making.** — Caustic potash made by adding slaked lime to boiling solution of potassium carbonate in not less than 12 of water, when calcium carbonate remains at the bottom and potassium hydrate remains in the clear solution. If solution be too strong, lime will not decompose carbonate, for reaction is reversible. When solution is evaporated, potassium hydroxide remains as clear oily liquid, which solidifies to white mass as it cools and forms fused potash of commerce, and often cast into cylindrical sticks. Potassium hydroxide is vaporised at high temperatures without decomposition. Half its weight of water suffices to dissolve it with great evolution of heat. Alcohol dissolves it easily. Bloxam. For further details see T. E. Thorpe's "Dictionary of Applied Chemistry." REGENT'S PARK.

[97221.]—**Telectroscope.**—"T. P." asks "will anyone be able to see round a corner?" We do, in fact, now see round a corner every time we view an image reflected from a reflecting surface. For example, if we focus the image of the sun reflected from a mirror a few feet from us, we find that we have the focal distance for the sun 92,000,000 miles away, and are entirely out of focus for the surface of the reflector, proving that there is no image formed there. This holds good for all distances and all angles. See proposition, "E. M.," No. 1807, "Where is the image?" I can see only one explanation of this fact: the sun and every object around is sending out vibrations, original or reflected, in every direction. Now, if a cone of vibrations from any object strikes a reflecting surface it is turned from its course, according to the well-known laws of reflection and incidence, and enters an eye in position to receive it. The diverging rays cannot form an image, and the particular rays of the sphere of divergence which converge to form the image depends upon the position of the observer with respect to the object and mirror. After entering the eye it is difficult to follow the vibrations of the locus of modification; but it seems probable that the vibrations pass through the soft layer of nerves without affecting them, reach the rods and cones, and through them set up vibrations at the ends of the nerves, which travel backwards to the sensorium, and are there modified into the image of the object from which they proceed; light and all the phenomena of vision thus being the luxuries of intelligence. By this bending of the cone of light at the surface of a reflector, we are able to see objects that may be behind us, or off the radius vector which joins the eye to the mirror; we see, in fact, round a corner. F. H. E.

[97235.]—**Melting Old Brass.**—It may be of interest to "Regent's Park," who, on p. 430, thinks it doubtful, to learn that brass is easily melted in a crucible on a smith's fire. In fact, if "R. P." puts a bit of brass wire into a kitchen fire when there is a good draught he will not see much of it afterwards. The temperature of the fusing point of brass varies according to its composition; but it must be a highly zinced brass which melts at 1,650° Fahr. The average temperature is nearer 1,800°. Which book has misled "R. P." this time? C. S.

[97259.]—**Keeping Oil - Engine Cylinder Cool.**—Doubtful whether it can be done satisfactorily without water; but the best way without is probably to have the outer surface of the cylinder covered with a spiral web of metal exposing large surface to the air, so as to radiate the heat. R. T.

[97261.] — **Pattern - Making.** — The querist should turn up the articles on pattern-making which appeared in this paper some time ago, and which were afterwards published in book-form by, I think, Lockwood and Son. If the querist is not going to do the casting himself, the foundry would make the patterns to his drawings. D. L.

[97263.]—**Organ - Building.** — In his remarks "W. A. J." states he has seen small organ-pipes, but never a full compass stop of 2ft. tone—surely he has not seen many organ-pipes or he would know that such stops as piccolo, flautina, flageolet, and 15th are all 2ft. stops, and in organs nearly always

have the full compass of the manuals, but if incomplete the top octaves are always inserted. "W. A. J." also asks about size of these small pipes in the upper octaves, he will find that top G of the Piccolo would be about $\frac{3}{4}$in. long (open pipe). I should certainly advise "W. A. J." to examine the interior of almost any organ: he would soon satisfy himself as to the size and range of 2ft. stops.

DIAPASON.

[97272.]—**Languages.**—For works in all European languages try Crosby Lockwood and Son, Stationers' Hall-court, E.C.; or D. Nutt, Strand—just by St. Clement Danes, if you are in London. Williams and Norgate, Henrietta-street, W.C., have also lists of such works, and would no doubt be able to show you suitable works; but it is not exactly clear what you want. Lockwood and Son have "Weale's Series," and there are grammars and dictionaries of, I believe, all European languages in that. The volumes may, however, be out of print.

LINGUA.

[97284.]—**Geometrical Progession.**—I accept the remarks of "Quivis" in the friendly sense intended, and do not suppose, when each has fully stated his case, there would be much room for divergence of opinion. Of course, in attempting to solve the equation $r = \frac{315 - x}{150 + x}$, which is indeterminate, by a convenient assumption one is exposed to a variety of objections, since r may stand for any integer we please, or for zero. Still "Quivis" has not attempted to disprove that on the hypothesis of r and x being positive integers, we could not arrive at any other conclusion than $r = 2$. But in these and similar cases the results obtained are only admissible by testing their applicability to the question in hand, and cannot be affirmed correct otherwise. Hence, while algebraically we can accept the solution $r = -1$, x = infinity, we cannot admit the trial results $r = o, 4$; $x = 315 - 57$. I do not know whether "Quivis" is referring to the closing remarks of my letter or to those of Mr. Paris when he says, "I should like to know what it means"; but as the subject may possibly interest others, and lead someone to discover a better method of solving general biquadratics, perhaps space may be spared for the following. As matters now stand, we solve biquadratics (when not directly resolvable into lower factors) by means of a cubic, but if it be possible to put the general biquadratic—

$$x^4 + a x^3 + b x^2 + c x + d = o$$

under the form $(z^2 + A x + B) z^2 + C x + D) = o$, where A, B, C, D are expressions involving a, b, c, d, then we can solve the general cubic—

$$x^3 + ax^2 + bx + c = o.$$

For, multiplying by x, we get—

$$x^4 + ax^3 + bx^2 + cx = o,$$

and putting $x = y + 1$, we have the biquadratic—

$$y^4 + (4 + a) y^3 + (6 + 3a + b) y^2 + (4 + 3a + 2b + c) y + (1+a+b+c) = o,$$

or— $$y^4 + \alpha y^3 + \beta y^2 + \gamma y + \delta = 0.$$

The four values of y obtained of course refer to the biquadratic in y; but if to each of these we add unity, *three* will be the solutions of the general cubic, and the fourth will be zero, corresponding to one obvious value of x in the multiplied cubic, and which gives $y = -1$ in its transformation. I have not succeeded with the suggested quadratic reduction, and so far no advance on Cardan's formula has been made; but I do not think we have reached finality yet—or, at least, I hope we have not.

West Norwood. HENRY T. BURGESS.

[97308.]—**Salicylate of Soda.**—This, though a valuable medicine, should be used with caution, as it is a very powerful depressant, and caused an inquest a few weeks ago.

West Didsbury. M. COLE.

[97336.]—**Roller Bearings.**—We beg to state that the application of properly constructed and properly manufactured straight and end-thrust roller bearings would be most useful on the various things referred to in that communication—namely, cabs, omnibuses, locomotives, traction engines, &c. We speak from an experience of nearly ten years, and are prepared not only to make applications in any of the cases we cite, but guarantee efficiency and durability. The matter in question is one of interest to engineers, and it will no doubt be of interest to them to know that the roller bearings manufactured by this company at their works at Birmingham are made from British material and by British labour, and they are the most successful roller bearings that have ever been manufactured.

MOSSBERG ROLLER BEARINGS, LTD.

[97359.]—**Flash-Powder.**—I should advise querist to leave the flash-powder described alone. He should bear in mind that picric acid is also known by another name—lyddite. R. W. M.

[97361.]—**Clock-Weight.**—Without seeing the two clocks, I am afraid it is rather difficult to explain the difference in motive power—that is, if they swing the same arc, and the pendulums are alike. Of course, if one only swings, say, $1\frac{1}{2}°$, and the other over 2°, that would account for the extra power required; and one reason I forgot to mention is a very confined space for the pendulum to vibrate in. I know one of my clocks with a dead-beat escapement and a very small space for the pendulum will very soon increase its arc a good degree on each side of zero when the case is removed. As regards the dead-beat escapement, the usual proportions are to give $1\frac{1}{2}°$ of impulse to each pallet, so divided that the impulse begins $\frac{1}{2}°$ before zero, and ends 1° afterwards, and these proportions are generally adhered to. With an escapement so planned you will find you can get plenty of swing if you largely increase the motive power, and to give much lift to the pallets is not considered advisable. But if your clock-weight is only about 5lb., falling 6in. a day, I should say you have nothing much to complain about, let the Cook and Son clock have what it may.

Ealing. F. M. MANN.

[97382.]—**Rats.**—To catch rats you must deceive them. Get an iron trap (gin) and adjust it so that a 2oz. weight will spring it when placed on bridge. Next get a box large enough for trap to lie in, and about 4in. or 5in. deep. Now set the trap, and lay it carefully in the box, and cover it over with tissue paper, and sprinkle a few bits of bread over it. The rat smells it, he finds it, and jumps on to the solid bottom (as he thinks), and is caught by the fore-legs. I have been quite successful that way. But, better still, keep all food out of their way, and as far as you can out of their smell, and do not drop or throw any food about. Food is what they come to seek. At my house we are very particular that way, and I have not heard or seen a rat, mouse, or beetle for a long time, and yet my neighbours are pestered with them. I have an earthen pan with cover for bread, and a hanging cupboard for other foods, and no rat or mouse can get in, and all crumbs are swept up. Starve them and set your dogs on them, and I think you will soon be free of them. W. M.

[97382.]—**Rats.**—Sixty years of observation have shown me that any one using poison for rats finds that he has poisoned something that he did not want to poison. Nevertheless, if poison must be used, I am assured by an old gamekeeper that the safest manner to do it is to mix a little strychnine with oatmeal, and scatter it about the rats' haunts. The use of cork or sponge saturated with grease, honey, &c., is abominable cruelty. In these cases the poor beast dies from enteritis after suffering lingering torture; whereas strychnine kills rapidly by fixing or "paralysing the muscles of respiration" (according to the notes of Palmer the poisoner). I know of a case where some rather ruinous farm buildings were made rat-proof by coal-tar asphalte poured into all the foundation interstices.

HAMMER.

[97391]—**Spun Glass.**—This was one of the stock exhibits at the Polytechnic in the old days, and the operator used to sell skeins of spun glass; but I agree with M. Cole (p. 520) that it is very "nasty stuff to handle." If I remember, the old gentleman at the Polytechnic had a gas blowpipe to heat the rod of glass, and the thread of glass was drawn out on a wheel worked by a treadle. Rods of coloured glass were used, and the "skeins" produced were "pretty." I do not think they were of much use. S. R.

[97398.]—**Climate of China.**—Madrid is also 40° N. lat., and it is very cold in winter; but it stands very high above the sea in the centre of Spain. But New York on the sea-coast is also about 40°, and it is also very cold in winter. The climate of England is affected by the Gulf Stream, which warms us in winter. G. A. HAIG.

[97406]—**Ulcer in Stomach.**—Drink tar-water.

COSMOPOLITAN.

[97407.]—**Carburator.**—You had better refer to back numbers of "E.M." for view of carburator given in articles on "Motor Tricycles." This will give you a good idea of general construction of the Longuemare type. Instead, however, of using a cotton wick, have a loosely-knitted sleeve of single Berlin wool made; this is much quicker in capillary attraction than the cotton, and should be changed regularly. There are two kinds of the Longuemare—one for motor-tricycles, the other for motor-cars. The chief objection is use of floats and levers, which require attention from time to time to keep in good order. I saw a simple form of carburator in use a short time back, made apparently out of an old square biscuit-box. Inside was a perforated plate fitted a few inches from the top, crammed with worsted, standing about 1in. above plate, the ends being clipped and then frayed out into a mop-like form. The hot air was drawn in at one side and over the surface out at the other. The owner would not give me much information; but I could see that it was reduced to simplest possible form, and afterwards I saw the car running very well with it. By pure air valve you mean early arrangement of Benz, now discarded. See "Auto-Car's" reply to yours for other information; also letters on troubles of Benz cars, which are interesting. See all your pipes, valves, and connections are large enough, and do not throttle anywhere, if you want high speed with engine. This has been a great fault with many would-be engine-makers.

MONTY.

[97413.]—**Electrical.**—To work a coil having 10oz. No. 16 on the primary and $2\frac{1}{4}$ No. 36 on the secondary, from four to six cells would be ample. It would be advisable to use the smaller number, if possible, as, with more cells, the primary wire would probably heat much, the platinum contacts of break might stick, and there would be risk of breaking down the insulation of the secondary. The size of the plates in each cell should be about 7in. by 5in. S. BOTTONE.

[97415.]—**Automatic Boiler Feed.**—"Electric Light Installations," Sir D. Salomons, pp. 100 and 101, gives elevation, section, and parts of Fromentin boiler feeder. This is probably what you require.

W. J. SHAW.

[97415.]—**Automatic Boiler-Feed.**—You have looked in the wrong "work." He has written a smaller work in one volume. "Electric-Light Installation and the Management of Accumulators," price 6s., Whittaker and Co.

RICHARD HUDSON.

[97418.]—**Microscopical.**—The magnification (linear) is directly as the distance. Hence if at 10in. the magnification is 40 diameters, at 33in. = 3·3 times the distance, the magnification is 132 diameters. S. BOTTONE.

[97419]—**Moisture in Showcase.**—Make showcase perfectly air-tight. Remove coloured or metallic goods. Place saucer with $\frac{1}{4}$lb. chloride of lime on each shelf and renew until cured. The saturation of CaCl will depend on the copiousness of moisture source. J. W.

[97420.]—**Swiftograph**—The publishers of the system are Jarrold and Son, 10 and 11, Warwick-lane, London, E.C., price 2s. COSMOPOLITAN.

[97420.]—**Swiftograph.**—I have tried this and gave it up in preference to Pitman's, which is the universally used system. "Teacher" may be had from Jarrold and Sons, 10 and 11, Warwick-lane, E.C., price 2s. If you are thinking of taking up shorthand, I should advise your starting with Pitman's, with which you can get assistance so easily. This assistance is really required, as there are many little difficulties to be overcome.

W. J. SHAW.

[97423.]—**Mercury Break for 10in. Coil.**—First, I have never seen paraffin oil used to cover the mercury, but do not know of any reason precluding its use. Alcohol is generally used; and if the layer is thick enough so that there is a considerable thickness above the highest point to which the "dipper" rises, there is no fear of firing. Some use distilled water, and these speak highly of it. In most cases a small quantity of finely-divided platinum is added to the mercury, so as to form an amalgam. S. BOTTONE.

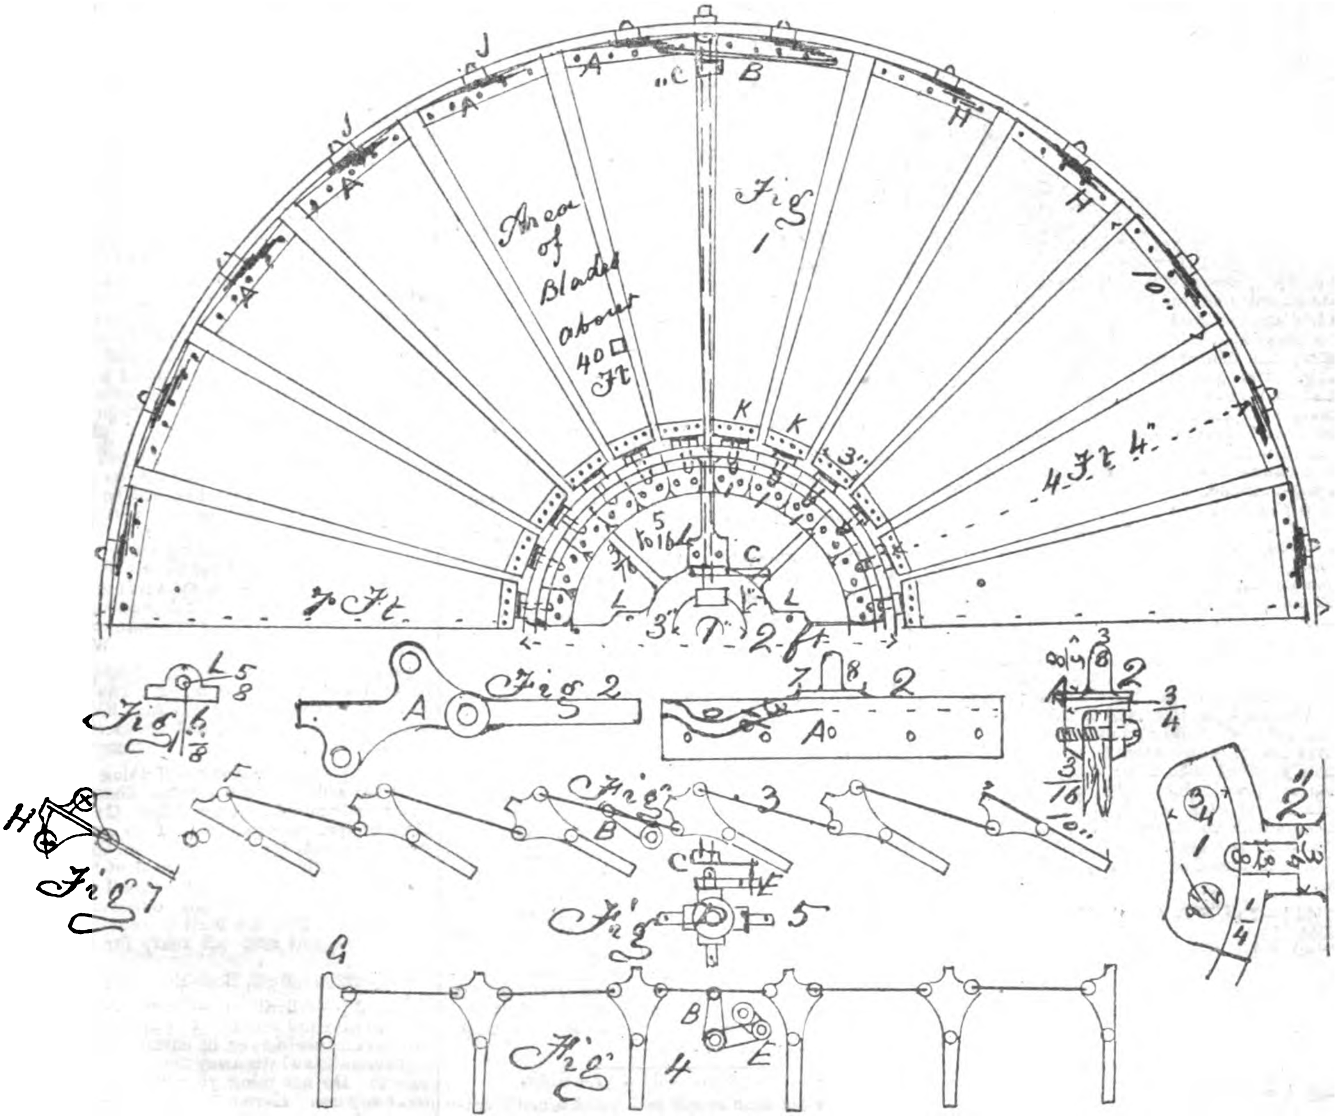
[97425.]—**Eyepieces.**—If, which is probable, the compound microscope is of the positive or Ramsden construction, it must be placed outside the cone of rays at a distance depending on its power of focal length. This distance can be experimentally found by viewing, with the eyepiece alone, any small object, and noticing its distance therefrom when in focus. This will be the distance it must be placed from where the image is formed by the o.g.

Corporation-street, Bolton. W. BANKS.

[97426.]—**Accumulator Charging Dynamo.**—To MR. BOTTONE.—Procure a sufficiency of tripolar laminations 2in. bare in diameter, to make up an armature 2in. long. Mount these on a suitable spindle and fit thereto a tripart commutator. Dress as usual, and wind with 6oz. No. 22 d.c.c., 3oz. in each channel. Wind the field-magnets with 2lb. No. 22 d.c.c., and connect up in shunt. At a speed of about 2,500 revs. per minute, this dynamo will give about three ampères at 15 to 20 volts pressure.

S. BOTTONE.

[97374.]—**Windmills.**—You do not give any particulars, but perhaps the following will suit you. Now we will say one 7ft. in diameter (that is rule of thumb) three of 22ft. × 12 = 264in., now allowing 1in. clearance, there being 24 blades or louvres to the fan—264 − 24 = 240, and 240 ÷ 24 = 10in. Here we have 24 louvres 10in. wide. Now the hub or boss of wheel will have to be 2ft. in diameter. That will make the blade at the junction of boss 3in. wide, and length 4ft. 6in. over all, less clearance. Now that will give 40sq.ft. of surface. Now the normal position of the louvres when at work for a gentle breeze will be an angle of 30°. They will not close more, but will open at right angles. I should think, as near as my judgment will carry me, this will be about what you require. About $\frac{3}{4}$H.P. to 1H.P. I have had no experience in these things and nothing to go by, and the dimensions you will find will, I think be about right. I have not the least doubt but what I shall be picked up if wrong in my calculations. The



question is, What do you mean to fix it upon? You will see that this is designed for a post about 8in. in diameter, and it will want some stays or guys to keep it safe—however, that is to come. Fig. 1 is the fan, and I have marked the dimensions. Fig. 2 2 2 are the shoes for the top end of blades A, and the shoes for the bottom are shorter and without ears. Fig. 2 is the thimble stop, the blades are shaped into the bottom, and returned through the hoop at the top; then the stop put in, as see 1 1 1, with two bolts, thus keeping it in its place. Fig. 3 shows you the blades coupled up in nests of six, so that there are four rods—i.e., striking gear, one each quarter of the diameter. That shows position (I might say normal working position) for working at angle of 30. (Fig. 4.) I ought to have said when the weight is on; when off it is at right angles, as shown, Fig. 4. B is the bell-crank that gives this motion: it is conveyed to it through the hole in the centre of shaft by a thrust-pin with a cross and links (as see Fig. 5), C the bell-crank near the eye, E the link, and D the cross, C H upon the face of fan giving the position. Fig. 6 is the step bearing for shaft L. Now, if you step out the arrangement showing blades, you will find that they do not correspond, and I have shown at Fig. 7, H, how they should be made: the shoes are made of malleable cast-iron, and the ears twisted, as shown, to bring them lineable with each other. The same etters refer to the same upon fan. The first view of shoe at Fig. 2 to the left is not right, but merely to illustrate the others; end and side views are right. Now you will want a post about 8in. in diameter to mount that upon, and it must be well stayed. There is some work cut out for you if you intend going in for one, but it will pay for doing, I think. The worst of them is that they roar with a breeze—at least, that is my experience when I have been to the Agricultural Exhibitions, but then it was blowing stiff. JACK OF ALL TRADES.

[97427.]—**Hard Compo.**—Is vulcanite, as used for roofing purposes, too expensive? REGENT'S PARK.

[97427.]—**Hard Composition.**—How would "Carton Pierre" do? Sort of paper pulp moulded up with plaster—used for ceiling ornaments. Several things of the kind nowadays—made from cellulose or paper. S. R.

[97428.]—**Grease.**—Cannot this grease be cleaned by simply dosing it with boiling water? The grease will float, and the "gritty matter" fall to the bottom of the vessel. Use plenty of hot water, and skim off the oil, or run it off through a hole inside of vessel. The grit will settle if time is allowed. S. R.

[97428.]—**Grease.**—Try a strong solution of sulphuric acid, especially if heated, and bichromate of potash added. REGENT'S PARK.

[97432.]—**Double Star in Cetus.**—The only reference to it I have been able to obtain is in Flammarion's *Les Etoiles*, where he says:—Preceding ζ and χ, there is a star of the 6th mag., often called χ^1 by mistake, which bears the No. 147 in the catalogue of W. Struve. It is a pretty double, sufficiently close; 6 and 7, at 3·5", white and bluish. Its co-ordinates are, for 1880, according to Flammarion, 1h. 34m.—11° 54'. There is no reference to this star in Webb's 4th edition; nor in any other work in English I possess. S. B. G.

[97432.]—**Double Star in Cetus.**—The star is Harvard Photometry No. 267 = Lalande 3137 = 263 Greenwich Catalogue 1880 = Σ 147. Its magnitude is in H.P. 5 89, in U.A. 5·8, in Heis 6, and in Manometria Nova 6. J. R.

[97432.]—**Double Star in Cetus.**—From the description given it is evidently 251 Ceti (Σ 147). R.A. 1h. 36m. 18s., dec. −11° 51·6', position 88·0, distance 4·0", epoch 1877, Dembowski; primary 5¼ mag., companion 7¼ mag., both white. It is shown in Peck's "Atlas," about 3° west of ζ Ceti; but not marked as a double star. W. B. D.

[97433.]—**Dynamo.**—The wire on the F.M.'s is not of sufficient resistance to balance the running resistance of the wire on the armature. Thus wire on A. = 6·5 × 0 67 ÷ 4 = 1·08 ohm; wire on fields 23 × 5 = 115 ohms, or, say, roughly, the ratio is at present as 1 is to 100, instead of being at least as 1 is to 350. If well constructed, with the armature running close to the tunnel, you have enough wire on your armature to give you about 100 volts and about 10 ampères of current, the machine running at, say, 1,200 revs. per minute, and absorbing about 2¼ to 3H.P. at work. To attain this result, you must get more wire on the fields. If there is room enough, you can do this by adding on 62lb. of No. 22—say 31lb. on each limb; if not, remove what you have on, and rewind with 46lb. No. 24 d.c.c. S. BOTTONE.

[97436.]—**Stamping Notepaper.**—It is not probable that you will be able to make the varnish yourself for this; but copal varnish coloured to suit is the nearest. To use, the die is removed, the colour painted on, then the surface wiped on waste paper, which removes all from the smooth surface, leaving it in the hollow letters; replace the die, impress, and stamp the paper.

West Didsbury. M. COLE.

[97438.]—**Gun-Cotton or Pyroxilin.**—Presuming you refer to the explosive variety and not to the soluble form, the following recipe will give good results:—Oil of vitriol, sp.gr. 1·845, 18fl.oz.; nitric acid (free from nitrous acid), sp.gr. 1·45, 6fl.oz; good cotton-wool 300 grains. Pull this latter out into ten little tufts, weighing about 30 grains each. Have two large and deep porcelain basins at hand, the second of which must be full of cold water; also two glass stirring rods. Now mix the acids together in basin No. 1, then immerse the tufts of cotton-wool one at a time, pushing them well under the acids as quickly as possible. Let the wool remain under the acid for nine minutes, remove by means of the rods to a flat dish, squeeze out as much acid as possible by the rod, then dash the cotton-wool into basin No. 2; stir about, place the whole under a running tap for 24 hours to wash away every trace of acid, collect the wool, dry in a cloth, pull out the tufts, and finish drying in a current of air. S. BOTTONE.

[97438.]—**Gun-Cotton.**—Gun-cotton ($C_{12}H_{14}O_4(NO_3)_6$) is formed by acting on cellulose or cotton-wool ($C_6H_{10}O_5$) with nitro-acid (a mixture of strong nitric and sulphuric acids); the cellulose does not undergo any apparent change, but on drying, it is found to be very inflammable. It is a nitrate or nitric ether, being cellulose, in which six atoms of hydroxyl are replaced by NO_2. H. F. L.

[97438.]—**Gun-Cotton.**—Gun-cotton has the formula $C_{12}H_{14}(NO_3)_6O_4$, and is, therefore, cellulose hexa-nitrate. It is made by soaking cotton wool in 10 parts of a mixture of one part of nitric acid (sp.gr. 1·5) and three parts of concentrated sulphuric acid. The clippings and other waste from cotton mills (such as is used for cleaning machinery), after purification from oil and fatty matters by treatment with alkali, and removal of string and rag, are passed through a machine, somewhat similar to a carding-engine, for the purpose of opening up the material, and subsequently through a cutting-machine. It is then rapidly dried by a powerful current of hot air in an automatic apparatus, and weighed off while warm into metal boxes holding 1¼lb., closed with well-fitting lids, and left in a cold chamber for 24 hours. The contents of each box are immersed by small quantities at a time in the usual acid mixture, remaining in for a few minutes, the temperature being kept down by cooling. The gun-cotton is removed from the mixture and pressed until it contains only 10 times its weight of acid. In this condition it is transferred to earthenware pots, closed with well-fitting lids, and left for 24 hours, the pots being surrounded by cold water. Then acid is extracted by centrifugal wringing-machine, and gun-cotton is carried in small portions at a time with great rapidity by means of a large paddle-wheel, revolving with a high velocity, into a large tank of water, and is thus drenched and rinsed. After two rinsings, and a complete wringing between each, is allowed to soak for 24 hours in water, maintained at 100° C. by injection of steam. The gun-cotton is then rinsed, placed in a pulping-machine, and again washed. It is then placed in a large washing-machine, and agitated with water for several hours, samples being tested for purity from time to time; 10cwt. are washed in one operation, and as this is the product of hundreds of distinct converting operations, a uniform lot of gun-cotton is obtained. Is now intimately mixed with 2 per cent. of alkaline carbonate and pressed into slabs (sp.gr. = 1). These contain 15 per cent. water, and may be cut with band-saws without danger. Now soaked in water to absorb 25 per cent. water, and then packed in wooden, well-closed cases in an uninflammable condition. R. W. M.

[97442.]—**To "F.R.A.S."**—The theoretical limit of vision of telescopes has reference to one of several empirical rules laid down by astronomers, and derived from a large number of observations. The one generally used is: Log. of aperture × 5 + 9·2 = magnitude of star seen with any particular aperture. The following example, taken from "Chambers," will explain. What is the smallest star visible in a 4in. achromatic?

$$\begin{array}{rr} \text{Log. } 4 = & 0{\cdot}6020 \\ & 5 \\ \hline & 3{\cdot}0100 \\ \text{Add} & 9{\cdot}2 \\ \hline & 12{\cdot}2100 \end{array} = \text{magnitude of star seen.}$$

(2) The formulæ here asked for has been given many times this last few years. For Ramsden or positive eyepieces, the formulæ is: Divide product of focal lengths of both lenses by their sum, minus the distance between them. Lenses both one focal length, say 2in., and separated 1·5in.

$$F = \frac{2 \times 2}{2 + 2 - 1{\cdot}5} = \frac{4}{2{\cdot}5} = 1{\cdot}6.$$

For negative or Huyghenian eyepieces, divide twice the product of focal lengths by their sum. Focal lengths as 3 to 1. Ex. Field-lens 3in., eye-lens 1in.

$$\frac{3 \times 1 \times 2}{4} = \frac{6}{4} = 1\tfrac{1}{2}.$$

(3) The field of view actually decreases. If the sky was divided into square degrees, and with one eyepiece four squares were seen, any stronger eyepiece would not show four squares. Field of view is governed by magnifying power chiefly, and is not influenced any way by a stop.

Corporation-street, Bolton. W. BANKS.

[97443.]—**Face-Plate.**—The weight certainly seems excessive. Extra thickness is, however, rather an advantage, as it renders the plate less liable to spring out of truth when irregular work is being clamped on it. I have seen face-plates sprung very much with the strain of the bolts. On the other hand, a heavy face-plate is cumbersome to get on and off the lathe, and also adds to the wear and tear of mandrel bearing, as well as running away with more time in stopping and starting the lathe. No; there is no fear of bending the mandrel, neither is there any reason why you should not employ as large a plate as the lathe will swing. No, you will not bend the saddle, but with 8in. of overhang there will be a lot of chatter. This may to a great extent be obviated by packing up between the underside of saddle and bottom of gap. Iron packing is best, and should be placed as near the front of bed as possible. You must expect to find the turning rather a tough job. I prefer a thick plate with a large number of slots to a thin one with few slots; these should be suitably arranged, where possible, for holding wheels with 3, 4, 5, and 6 arms, also to suit any angle-plates that you may have by you.

J. T. A.

[97446.]—**Deflection of Oak Beam.**—Timber beams supported at both ends, deflection allowed is $\frac{1}{40}$in. per foot run.

$$V = \frac{n\,W\,c^3}{e\,I}$$

V = deflection in inches.
W = load in pounds.
c = length in inces for beams fixed at one end; half length if supported at both ends.
I = moment of inertia.
e = modulus of elasticity.

Rectangular and square the inertia—

$$I = \frac{b\,d\,3}{12}.$$

Strength of rectangular beams: b = breadth; d = depth; L = span. For fir, safe distributed dead loads in cwts. $= \dfrac{b\,d^2 \text{ in inches}}{\text{L in feet}}$. For English oak, 1½ above load for fir. Value of a: Supported at both ends, loaded in middle, uniform cross section, ½; uniform strength and depth, ¼; uniform strength and breadth, ⅓. (Kempe tables.)

REGENT'S PARK.

[97448.]—**Cement.**—Caseine 10, water-glass 60. Apply quickly, and dry in air. Or: Pyrolusite 80, zinc-white 100, water-glass 20. When once fused forms glass-like mass, of great adhesive power.

REGENT'S PARK.

[97448.]—**Galvanometer.**—These galvanometers are not graded to any standard. Hence your only plan will be to take a fairly good cell, which has been made up about 12 hours, and test it on the quantity side for current, and note the deflection; then on the intensity side for voltage or pressure, and note this likewise. Measured in volts, all Leclanchés give about 1·4 volt per cell, while the current may vary from 0·1 to about three ampères per cell, according to its condition, resistance in circuit, &c. S. BOTTONE.

[97449.—**Velocity of Sound.**—The elasticity of a gas is to be measured by the pressure which is on it. If we take the pressure of the air as 15lb. to the square inch, the pressure in poundals per square foot will be = 15 × 144 × 32. The density of the formula is absolute density—that is, the ratio between the mass of a body and the space it occupies. A body has unit density when a cubic foot of it weighs 1lb.; the density of the air will thus be $\frac{1}{13}$. Hence the formula becomes—

$$V = \sqrt{15 \times 144 \times 32 \times 13} = 940\text{ft.}$$

A slightly different result will be obtained if more accurate values be taken for gravity, and for the density and pressure of the air. ARITHMOS.

[97449.] — **Velocity of Sound.** — E = bulk elasticity of air = ratio of small increment of pressure to small decrement of volume for unit volume. According to Boyle's law—

$$\begin{aligned} PV &= (P + p)\,(V - v) \\ &= PV - Pv + pV - pv. \end{aligned}$$

Neglecting the small quantity $p\,v$ we have—

$$Pv = pV$$

$$\therefore P = \frac{p}{v}V = E.$$

P is atmospheric pressure at time of experiment. Taking atmospheric pressure = 1,016,000 dynes per sq. cm., and density of air = ·001293, we have—

$$\begin{aligned} V &= \sqrt{\frac{1{,}016{,}000}{{\cdot}001293}} \text{ cm. per sec.} \\ &= 28{,}000 \text{ cm. per sec.} \\ &= 920\text{ft. per sec.} \end{aligned}$$

R. W. M.

[97450.]—**Drum Armature.**—To MR. BOTTONE.—Whether you will be able to rewind the drum without removing *all* the coils depends entirely on the extent of the injury. If only the coils last wound on are affected, you possibly may not have to remove all; but if any of the first arcs are implicated, it will be impossible to repair without. As you have my book, you will see at p. 86 that the sections on the armature are numbered 1, 1*a*, 2, 2*a*, &c.; so if you turn the armature over, after having wound each section, so as to bring the divisions marked 1, 2, 3, 4, &c., to the top, you will be doing right—whether you turn it over to the right or to the left. S. BOTTONE.

[97451.] — **Commutator.** — Besides your usual insulating packing between commutator sections and clamping nut, put a stoutish washer of ebonite or vulcanised fibre. This will take off some of the twist strain. Mica can be bought of practically uniform thickness, and if desired can easily be split thinner by means of the blade of a thin knife.

S. BOTTONE.

[97452.]—**Show-Case.**—Under similar circumstances I have found a shallow tray of sulphuric acid very effective in reducing the deposition of moisture. There is no cure so long as the inner and outer surface are at considerably different temperatures, and moisture present.

Corporation-street, Bolton. W. BANKS.

[97454.] — **Overtype Dynamo.** — To MR. BOTTONE or MESSRS. WEBSTER MICHELSON.—Armature 8in. dia., 8in. long, before winding, F.M. tunnel 8⅜in. dia. Pole-pieces should embrace together two-thirds of the armature; armature to be wound with 22lb. No. 14; pole-pieces 9in. long, 16in. across the face, including the aperture of tunnel; F.M. cores 5in. dia., 9in. long, cylindrical, wound with 78lb. No. 20, and connected up in shunt. For the series coil use 12lb. No. 12; speed about 1,300 per minute; commutator at least 4in. dia. in 36 sections. A machine to run three lamps of 16c.p. 55 volts, overtype drum pattern, would have an armature about 6in. long, 2¼in. dia., wound in 24 sections with 1lb. No. 22. The field-magnets should be of 1in. substance, 6in. long, with 3½in. winding space; and the tunnel, embracing as before two-thirds of the armature, should extend the whole length of armature; the field-magnets should be wound with 11lb. No. 24 d.c.c. S. BOTTONE.

[97456.]—**Launch.**—I should put a ½ or 1H P. motor in; the ¼-horse will not be of much use, particularly as the propeller will be working at a disadvantage, inasmuch as you wish it to be above the level of the keel. The best way to get over the difficulty is to have a lifting propeller—that is, a shaft with a universal joint in it. The size of propeller will be governed by the amount of water your boat draws. The pitch will depend upon the speed of the engine and the pace you want to go. Allow 40 per cent. for slip. W. J. SHAW.

[97456.]—**Launch.**—Seems rather small for 18ft. long; 1H P. would be better. The Yankees, or some of them, in their naphtha launches, allow 2H.P. for 18ft. length, and about 12in. by 12in. dia. and pitch. REGENT'S PARK.

[97458.]—**Observatory.**—Nothing less than 8ft. diameter will do for a 6in. tube. There is no objection to galvanised iron for sides. Cost depends on class of structure required. I do not remmend a revolving dome for so small a telescope. A square structure, with ridge roof formed of light sailcloth shutters, answers admirably. I shall be pleased to lend querist plans of an observatory of this description. They are built in sections, same as a greenhouse, and sent out ready for fitting up by levels.

Corporation-street, Bolton. W. BANKS.

[97462.]—**Vibration.**—I have no doubt you will have to grin and bear it. It is always the case near railways on viaducts or in cuttings, and very often more vibration a little away than if you were planted on top. Do not think your trench operation will be of any use. Have noticed the nuisance on or by South-Eastern and North-Western, and no doubt on all lines it is the same. Of course, if companies laid their metals on stout rubber it would go some way towards prevention; but that you can hardly expect them to do. Wet and dry makes a difference, I have noticed. REGENT'S PARK.

UNANSWERED QUERIES.

The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered, are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.

Queer Cannibal Rites.—That cannibalism still flourishes in parts of West Africa, in spite of the advance of civilisation, is shown by the letter of an officer now serving in Nigeria. The people of the town of Igigger, for instance, eat all their prisoners, and even the bodies of the slain after a battle. Their burial customs are also strongly reminiscent of cannibalism. After a death the relatives of the lamented one strip the body, and at the end of four or five days roast it over a slow fire on a bed, with pots of yams, rice, and meat below. The body is basted with palm oil, which drips on to the food, of which everyone has to partake to show that they did not poison the deceased.

QUERIES.

[97464.]—**Shortest Day in Trinidad.**—I am living in Trinidad, 10° north of the Equator, and expected to find that the 20th of December would be the shortest day of the year. So far as my observations extend at present, the shortest day appears to be somewhere in the latter half of November. Can this be possible? Or can it be due to an increase in the length of the twilight making the days in December apparently longer?—TRINIDAD.

[97465.]—**Carbon Transmitter.**—In making a carbon transmitter, say the Ader type, is it absolutely necessary for the diaphragm to be of pine? Would teak or deal suit as well? If not, what sort of pine?—ANGLO.

[97466.]—**Torpedo-Boat Destroyer.**—Can any of your readers tell me where, in London, I could see an exhibition model of a torpedo-boat destroyer? To the best of my belief, there is no such thing in South Kensington Museum; at any rate, there was not one when I visited that place some months ago.—T. J. HOAR.

[97467.]—**Rook Rifles.**—Can any of "ours" give full information *re* ·22 rim-fire rifles? Any tests as to distance carried, accuracy, and penetration with both the ·22 long and ·22 short rim-fire cartridges would greatly oblige. The ·300 I find too powerful; but I am just afraid the ·22 would be weak enough for either rooks or rabbits. Any information as to the most suitable magazine rifle for this size of cartridge, or guidance as to the best bore of rifle to use, would be of interest.—W. S.

[97468.]—**Protecting Steel Surfaces.**—Wanted, information as to best method of protecting finished steel rods and pins subject to light friction (but which cannot be greased or lacquered) from rust. Perhaps the oxidising process as applied to watch-cases might answer, if anyone can describe the process?—F. L. H.

[97469.]—**Tender Feet.**—Can any of "ours" give me advice? My duty compels me each winter to stand and work on flagstones, some of which are cold and others warm, in a large public kitchen, and the ball of right foot is so tender that I limp. Is it rheumatism? How can I get ease? I have seven more weeks to be there. Is it caused by the stones, or what? A remedy would be a blessing.—A. STACEY.

[97470.]—**Motor-Cycles.**—Will the writer of the articles on motor-cycles kindly say where ball-bearings suitable for the back axle (of the tricycle illustrated) can be procured, as I am quite unable to get bearings at all like those illustrated on p. 542 of the "E M." of Aug. 4, 1899.—J. S. BROWNE, Ashfield House, Belfast.

[97471.]—**Piano Organ.**—I have a piano organ with the usual handle. I wish to make it self-acting. Information as to electric, clockwork, or other motor, with details, would be greatly esteemed.—A. SIMS.

[97472.]—**Oil-Engine.**—Will someone give drawings sufficient to enable me to make an oil-engine of $^{1}/_{10}$H.P. to ½H.P.?—GERARD S. PECK.

[97473.]—**Pocket Accumulators.**—I have a pocket accumulator, 4-volt cells, 4in. by 5in. by ¾in., with two plates in each cell. I have put new plates in them, and would like to know what to seal the tops with. The cells are of ebonite.—AN OLD READER.

[97474.]—**Knocking in Gas-Engine.**—I have read with interest the recent replies *re* the above. I, too, have a small half-horse oil-engine which makes a fearful noise at every explosion, as if it would break the whole thing to pieces. I have put a new pin, well-fitted, into piston-head, but it is no better. The rings are new, and part of explosion escapes. Can this be the cause of the noise? If you could suggest a cure, I feel sure you would oblige more readers than you can imagine.—A COUNTRY PARSON.

[97475.]—**Telephones.**—I have a pair of these between two rooms but sometimes can scarcely get a sound. They are evidently foreign manufacture. The microphone (Hunnings) is placed horizontally — two semicircles of tin-plate separated by ebonite slip, with granulated carbon resting upon all. I sometimes think the ebonite slip must prevent the two half-circles vibrating. I use two cells at each end. The cell bells work well, but the speaking is a failure. Could anyone suggest a cure?—A COUNTRY PARSON.

[97476.]—**Soldering.**—Will some reader kindly inform me how to tin carbon ready for soldering it to brass, for bichromate cell?—SEEKER.

[97477.]—**Brasswork.**—Will someone please tell me how to clean and brighten brass or copper beaten work, so as not to tarnish?—SEEKER.

[97478.]—**Electric Light and Gas.**—With price of gas at 3s. 8d. per 1,000, what price would electricity have to be to make lighting bill about the same? It is a factory that has to be lighted, and nothing would be saved in lessened cost of decorations.—G. E. O.

[97479.]—**Induction Coil.**—I have made a coil which gives a spark of 1in. in length. If I pass its current through a Tesla coil, can I increase it to 5in. or 6in.? May the secondary wire of the Tesla coil be covered with cotton instead of silk? Is there anything more known about the system of winding coils invented, I think, in Belgium, which gives 6in. or 7in. spark with not much more than 1lb. of secondary wire? I put my coil in a jar full of paraffin, in which I had dissolved paraffin-wax to the extent of making it a thick liquid; but it only slightly increased the length of spark. If the secondary wire were to be double-covered and the layers separated more, is it probable that a liquid insulator would be superior? It would be no trouble to keep a coil in a small tank, if it greatly decreased the cost of making.—H. M. S. L.

[97480.]—**Chlorine and Fluorine.**—Would some of your chemical readers kindly state briefly the method which was used to isolate fluorine, and also give its appearance and properties? Has chlorine ever been solidified?—HALOID.

[97481.]—**Platinum Resistance Thermometer.**—Could any reader give full description, with method of making and using, of the above? Details wanted.—RUN.

[97482.]—**Lichens.**—Will any reader inform as to the best method of preserving fungi and lichens for collection purposes?—BOTANY.

[97483.]—**Stains for Gun-barrels.**—Could any reader of the ENGLISH MECHANIC give me any information as to the best stains for gun-barrels, and how applied?—MECHANIC.

[97484.]—**Lens Problem.**—A lens is closed completely by an iris diaphragm. The diaphragm is opened with uniform motion from nothing to full aperture. Compare the amount of light that passes through with the amount that would have passed through had the diaphragm been fully opened all the time.—IRIS.

[97485.]—**Sparking Coil for Motor-Car.**—Will any friend give particulars of coil similar to Blake's coil? I simply want the sizes and weights of both primary and secondary, the primary to be supplied from a 4-volt secondary battery.—F. W. B.

[97486.]—**Organic Identification.**—I should be extremely obliged to any readers who could tell me of a good book on "Organic Identifications."—H. J.

[97487.]—**Heating by Gas.**—Some time since it was stated by a very good authority in these columns that although the incandescent mantle light was caused primarily by an atmospheric Bunsen flame, rendered incandescent by its action on the mantle, yet that the product of combustion was mainly carbonic-acid gas, and not the poisonous carbonic oxide. Does the same hold good with regard to open-fire gas warming stoves, where a Bunsen atmospheric flame plays on asbestos (so called) fuel or on asbestos fibre, causing the fuel or fibre to become incandescent, giving out both light and heat? I notice that some of these open fires are provided with condensing tubes which condense vapour into water, and remove the same with, no doubt, sulphur and ammonia impurities, and probably a little carbonic acid. They have no flues, so that the other products of combustion escape into the room, from which I infer that the makers recommend them as not more harmful than the flames from ordinary illuminating jets. If they emitted carbonic oxide (CO, monoxide of carbon) in any considerable proportion other than a mere trace, one would think they would be dangerous to life.—R. L. S.

[97488.]—**Soap.**—Two or three years ago "Lancastrian" gave details for making emollient soap without boiling, on the domestic scale. I have made several lots quite satisfactorily, and costing next to nothing, except for scent. I cannot scent it strongly enough to kill the crude smell of the fat. Delicate scents, as oil of geranium, are too fleeting; oil of cloves is more lasting, but too pungent. Can anyone help me to produce "Brown Windsor," or similar aroma, and the quantity necessary for 9lb. or 10lb. of soap—i.e., 6lb. of fat?—BUSHMAN.

[97489.]—**Rotundity of the Earth.**—Would "F.R.A.S." be good enough to say when was enacted the curious statute forbidding the teaching of the rotundity of the earth? I thought the rotundity of the earth was known and taught long before any of our statutes were framed.—ROTA.

[97490.]—**Motor-Car Carburator.**—Will any of "ours" give rough sketch of carburator similar to the one used on the Benz Ideal, and also dimensions of same for 4H.P. engine? Any information will be thankfully received.—F. W. B.

[97491.]—**Moist Air in Rooms.**—I have a room lighted by long, narrow window and a big skylight (nearly full length of room). The room is heated by a gas-fire on Bunsen burner principle, the waste heat going up the chimney. Finding that a great deal of moisture is caused by heating, I should like to know if air warmed by gas is not so dry as when coal is used; or is the skylight (with the consequent condensation from the cold outside) a sufficient explanation, no matter how the room be heated?—STUDIO.

[97492.]—**Collapsible Canoe.**—I wish to hear where I can find good designs of collapsible canoes or punts. Also, would a canvas boat, 12ft. long and 3ft. wide, be safe?—R. W.

[97493.]—**Excursion Trains.**—I have always understood that Thomas Cook was the inventor of excursion trains in 1841; but in the account of the life of a gentleman who died only last week it is proved he travelled by an excursion in 1840, and the original "bill" relating to this train is in the hands of his relatives.—EXCURSION.

[97494.]—**Shanks' "Times" Patent Enamelled Cast-iron Bath.**—Please give No. and date of this patent specification, or else tell me how to get at the screw-down valves to repack them, and at the waste valve in order to shorten the wire or chain by which it hangs. I began unscrewing the +-shaped handles in order to lift the porcelain cover which forms the soap-dishes. Their threads fit so tightly, however, that I feel sure they are not intended to be removed from their spindles, and that the porcelain can be detached in some other way.—GLATTON.

[97495.]—**Galvanometer.**—Can any reader give instructions for making a galva. for use with a magneto generator? Required also the resistance one of "Ericson's" telephone call generators, will ring through. The one I have appears to be wound with 40 wire.—CONSTANT READER.

[97496.]—**Silicate of Alumina.**—Said to be a combination of aluminium and flint. Where could I obtain a small quantity of this? or how could it be made?—S. W.

[97497.]—**Carburator.**—Can any reader kindly inform me how to construct a carburator for petroleum spirit, to be used with a 2¼H.P. motor?—O. H.

[97498.]—**Gas-Engine.**—If any of your readers could give me some information about a gas-engine, I should be much obliged. I have made an engine, 2in. bore cylinder, 3in. stroke, and the difficulty is that the explosion takes place too soon, and drives the wheels backwards. Does the fault lie with the ignition-tube? At first I had one 4in. long with a ⅝in. hole up it; but I replaced it with one of the same length, but with a $^{3}/_{16}$in. hole up it. I may mention that it gets red hot about 1in. from the bottom. How can I prevent the exhaust being drawn back into the cylinder? I have tried a stronger spring, but I find it is not much better. If I turn the gas and air supply taps nearly off, the piston sucks the exhaust-valve back. I also find that I cannot keep the wheels going round on account of the high compression—it stops the engine completely. Do I get too much gas and air in, or is this very high compression necessary? Are two wheels 8in. diameter large enough?—DAVID BARRATT.

[97499.]—**To Mr. Bottone.**—We have the electric light in our streets, and I believe it must be an alternating current. I notice, when swinging my walking-stick around, so that the light from one of the street lamps shines on the same side that you are standing on, the stick, instead of going smoothly round, seems to go by a series of quick moves and stops, as near as I could make out, from 38 to 44 moves per second. I also note that the light only lasts about one-third, and the dark about two-thirds. Do we have only one-third of the light that we would have from a continuous current, or does the retaining power of our eyes make up for the defect?—MACKIE.

[97500.]—**Cutter-Bar for Slide-Rest.**—Can any reader recommend me a cutter-bar or tool-holder for the slide-rest for general work? I have tried a Haydon bar, and find the cutters slipped through, and were not properly gripped after I had only used the bar for about a week. The jaws appeared to be soft, and to lose their shape and place.—C. W., Hull.

[97501.]—**Breech for Model Cannon.**—I am making a model cannon, 9in. long, to fire ·221 rim-fire cartridges. Will someone please give me some idea how to construct a simple breech? I want something that is quick to work, safe, and easy to make.—LENS.

[97502.]—**Motor for Car.**—I am desirous of constructing a motor similar to designs now appearing in "E. M.," but want to use the crank-cheeks as flywheels, and inclose them in crank-chamber. Will the writer of the articles kindly advise as to what diameter, thickness, and weight the two flywheels should be, and how to calculate same? Is it advisable to counterbalance them? If so, please say how to lay it out?—VOLANT.

[97503.]—**Fancy Mice.**—Can some reader kindly describe suitable dietary, &c., for Japanese "waltzing" mice? Also, in what respect does this breed differ from the more common of the tame varieties?—MAUSER.

[97504.]—**Electrical.**—In an electrical experiment, it is desired to "cut-in" and "cut-out," one by one, the ten cells of a battery. Please describe a simple switch-board, or other suitable apparatus, for doing that.—X. R. Y.

[97505.]—**Nicol Prism.**—To LEWIS WRIGHT OR OTHERS.—My Nicol prism polariser (1in. clear field) for projection microscope has got badly scratched right in the middle of the field of one of the end faces. Can this damage be rectified without injuring the prism? If so, how? Would recutting or repolishing the scratched end impair the effectiveness of the prism?—SCOTUS.

[97506.]—**Bleaching Wax.**—Would any reader kindly tell me how to make brown wax white—in large quantities?—EMBOSSER.

[97507.]—**Frame Food.**—I have been told that "Frame Food" is a valuable preparation for invalids. Can any reader give particulars, and, if possible, an analysis of same?—O.

[97508.]—**Dead Batteries.**—Having some dry E.C.C. batteries gone dead or exhausted, will Mr. Bottone kindly tell me how they can be made effective again? I have a dynamo charging twelve lithanode cells for house lighting.—STRAX.

[97509.]—**Engine Priming.**—I have a 8H.P. portable engine which primes a great deal. Cylinder-bar rebored, and new slide fitted, and is constructed different to the old one. It has a deeper and larger recess for exhaust steam, but is worse with the new. Will some kind reader give most likely reasons for same?—W. D. M. O.

[97510.]—**Finlay's Comet.**—Will some of "ours" please say how far the path Finlay's comet is now travelling on is from the path it followed in 1893? And if the fact of our planetary system travelling so rapidly (please say how far a year) has anything to do with the so-called lost comets that used to be periodic? Further, what effect would our moving have on the lately expected Leonid showers?—EFE.

[97511.]—**Radiometers.**—What is the latest accepted theory as to why the vanes revolve?—EFE.

[97512.]—**Manchester Dynamo.**—Will Mr. Avery advise me for dimensions and quantity of wire for a Manchester dynamo output, 5 amps. at 50 volts pressure? Also dimensions of cores, fields, and armature?—JOHN ELLIS.

[97513.]—**Sporting Requisites.**—Can some of "ours" say what restriction there is to carrying ammunition on board steamers for the Cape? I have a young friend who is very anxious to take out a small rifle, costing only 15s., which fires bulleted caps, and also takes the short and long ·22 rim-fire cartridges. Will he be charged according to number or space occupied?—because 1,000 of these take up less room than 100 ordinary rifle cartridges. Any information regarding the carriage and duty on larger sporting requisites would be welcomed by—A CONSTANT SUBSCRIBER.

[97514.]—**Hydraulic Lift.**—Will someone tell me what horse-power will be required to drive a hydraulic jack to lift 100 tons to a height of 10in.? The ram is 5in. diameter; the small plunger is 2in. diameter and 3in. stroke. A steam turbine is to be used, running at a speed of 30,000 revolutions per minute, which is reduced to 500 revolutions per minute. The plunger works both ways. If 500 strokes is too quick for the plunger to work, it can be further reduced.—T. W. D.

[97515.]—**Waterwheel.**—I have a supply of water which will give 4,400c.in. per minute at a pressure of 200lb. per square inch. Will someone kindly tell me what horse-power this will give with a wheel running at a speed of 30,000 revolutions per minute, and state the size of the nozzle and the diameter of the wheel?—W. D.

[97516.]—**Edison-Lalande Battery.**—Could Mr. Bottone or any other electrician inform me what differ-

ence it would make to charge the Edison-Lalande battery with caustic soda instead of caustic potash, the former being cheaper than the latter, and what chemical reaction takes place in each case? I have tried both, and find that the potash gives better results—whether more pure or not I do not know; the oxidation of the zinc in both cases is alike. The old battery I had for igniting the vapour in my oil-engine had a carbon and a zinc pole, and potass. bichromate was the chemical used. Which do you consider is the best of the two, or is there a better battery for such work in the market?—CYMRO.

[97517.]—**Propellers.**—Will some of "ours" please give the general average "slip" of the propellers in a knot of such ships as the *Majestic* when going at the rate of 15 knots an hour? This can be got at by giving the "pitch" of the blades and the number of revolutions per knot. Also give "working" surface of blades. An answer to the above questions also, when vessel is going at the rate of 20 knots. If "head resistance" is a fallacy, I want to see what proportion of friction the blades are responsible for in comparison with the hull at the increased speed, leaving out of the question air resistance? Any ship will do as an illustration of the above questions. —EFE.

[97518.]—**Clock Weight.**—How is it that a reduction of weight tends to increase the pendulum arc? Two clockmakers, in different towns, say this is so. One would expect that increase of weight would give increase to the force which produces the oscillation. I tried the experiment on a sidereal regulator, removing about an eighth part of the weight. The arc, which was small before, is certainly no less, possibly a trifle greater, and the beat is more even. The escapement is dead-beat.—ANTARES.

[97519.]—**Angle of Double Stars.**—One is accustomed to take the larger star as centre, to measure the angle of a pair. When the two are sensibly equal, as ζ Aquarii (p. 484 of last week), which should be selected for centre? Perhaps "F.R.A.S." would kindly state his practice? I have missed the "E. M." for a long time, and am delighted to find his letters as excellent as ever. —ANTARES.

[97520.]—**Cataloguing Books.**—Can any of our kind readers inform me the best practical way of cataloguing a private library, comprising about 1,500 books, or what books I can get bearing on the subject? The books are contained in two bookcases and a series of shelves arranged each side of fireplace.—J. C.

[97521.]—**Pronunciation of Astronomical Terms.**—Is there a dictionary which gives the pronunciation of astronomical terms? For example, how is "mare" pronounced—with the *a* broad or sharp? In designating the stars, how are the Greek letters pronounced?—N.

ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries, put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

*** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

The following are the initials, &c., of letters to hand up to Wednesday evening, Jan. 24, and unacknowledged elsewhere:—

J. H. EVANS.—Filter.—A. H.—H. A. H.—R. H. Parsons. —Young Mechanic.—H. Jay.—M. B., Galway.—J. R.— Arcturus.—A. Stamwitz.—Richard Inwards.—S. Jesse. —Glatton.—Jack of All Trades.—Theodore Brown.

C. G. ROBEY AND OTHERS.—It is simply impossible for us to insert a tithe of the letters that have reached us on Field Armour or the Date of the Century, and in no case can we either return letters sent or spare time or space to argue with individual correspondents about the merits of their suggestions. We are not infallible, but our business here is simply to print *what we think readers will read*, as far as space permits.

A. HORNER.—Thanks for recommendation. The set of "best books" has been sent to your friend, and your card inclosed. We venture to think it will be not the least appreciated of her wedding presents.

CHARLES WHITFIELD.—Yes, several; we must refer you to back volumes for dates and details. You give no address in your letter, so if papers, which are being sent simply to Wantage, do not reach you, it is not our fault.

CHARLES THOMAS.—You can probably achieve your object by passing some of the strongest alcohol through caustic potash. There is no "particular kind of sugar" from which to make it, and a license would be required if you set up a still. (2) Use the ordinary rubber solution sold at the leather-sellers' shops.

HENRY CARR.—Some use gum with the starch, others use glue. There are many recipes in back volumes, and probably the best is the old-fashioned starch to which some shreds of spermaceti are added, or paraffin-wax.

PRONUNCIATION.—Do not think much attention is paid to the actual sound of the vowels; but query is inserted in a modified form, and perhaps some of our readers who attend the meetings will reply. Usage settles the matter, if there is any settlement.

AMATEUR.—There are several works on brazing and soldering, and many replies in back volumes. Useful works are advertised weekly in the "Sale" Column. See p. vi. last week.

W. INGRAM WHITE.—You could look through the library at the Patent Office, and consult the catalogues of such publishers as Longmans, Spon, Lockwood and Son. Mitchell's "Manual of Practical Assaying," Longmans, is a good work. You can see many at the library mentioned, and can then form an opinion as to which will suit.

TRITON.—Have heard of Eucalyptus oil being used as an inhalation; but do not know of any physician who has recommended lozenges containing that oil as a preventive of influenza.

J. B. R. S.—Salicylic ointment is stated to be a good remedy for corns and warts. (2) Dry rot is a fungus. The holes in the furniture are caused by a species of Anobium - the Death-watch beetle. Please see the back volumes for many replies.

PHOTO.—Please send sketch of the hand-camera shutter (97364).

IN TYPE.—Hugh Alexander.

CHESS.

All communications for this column to be addressed to The CHESS EDITOR, at the Office, 332, Strand.

PROBLEM No. 1710.—By T. TAVERNER.

Black. [6 pieces.

White. [10 pieces.

White to play and mate in two moves.

(*Solutions should reach us not later than Feb. 5.*)

Solution of PROBLEM No. 1709.—By J. JONES and W. SHINKMAN.

Key-move, B-K 2.

NOTICES TO CORRESPONDENTS.

PROBLEM No. 1709.—Correct solution has been received from N. M. Munro, Richard Inwards, A. Tupman, A. H. W., J. E. Gore, Quizco, Rev. Dr. Quilter, H. Hall, F. B. (Oldham), W. Masters, Jas. Mason, W. Taylor.

H. B. F.—Only solution as above.

PROBLEM No. 1710.—In consequence of two misprints in the diagram, which we much regret, it is again published, and will be found to be a very excellent problem. Solutions are requested by Feb. 5.

SPECIAL OFFER.—CHEAP VOLUMES.

In the course of the next few months we are compelled, owing to the making of the new street from Holborn to the Strand by the London County Council, to remove our Offices and Printing Works. Due notice of our removal will be given shortly. In the mean time, to reduce stock and save trouble of removal, we offer readers desirous of making up sets of back volumes *any volume* in the list below at HALF PRICE, or post free for 4s. 1d.

Any reader desirous of making a free library or working men's club a present of a few sets of volumes will find this a favourable opportunity. The offer is only available till our removal.

TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

5s. 6d. for Six Months and 11s. for Twelve Months, post free to any part of the United Kingdom. For the United States, 13s., or 3dol. 25c. gold; to France or Belgium, 13s. or 16f. 50c.; to India, New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-Office Order. Back numbers can also be sent out by the ordinary newspaper post at the rate of 3d. each.

Vols. XIII., XXVI., XXVIII., XXX., XXXII., XXXIV., XXXIX., XL., XLI., XLII., XLIII., XLIV., XLV., XLVI., XLVIII., L., LI., LII., LIII., LIV., LV., LVI., LVII., LVIII., LIX., LX., LXI., LXII., LXIII., LXIV., LXV., LXVI., LXVII., LXVIII., also LXIX., price of which is 7s. 7d. Post free.

Indexes to Vol. LI., and to subsequent Vols., except Vols. LIII., LV., LVI., LVII., LIX., LXI., 3d. each, or post free 3½d. Cases for binding 1s. 6d. each.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each post free from the office (except index numbers, which are 3d. each, or post free 3½d.)

NOTICE TO SUBSCRIBERS.

Home Subscribers receiving their copies direct from the Office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a PINK WRAPPER, as an intimation that a fresh remittance is necessary if it is desired to continue their subscription.

Foreign Subscribers will have the Pink Wrapper sent ONE MONTH before expiration, in order to give them time to forward fresh remittance before subscription expires.

ADVERTISEMENT CHARGES.

The Charge for Advertisements in the Columns headed:—

For Exchange.
For Sale.
Wanted.
Addresses.
Situations.

is Sixpence for the first Sixteen Words, and Sixpence for every succeeding Eight or part of Eight, which must be prepaid. No reduction on repeated insertions. Advertisers should state under which heading they wish their announcements to appear.

The address is included as part of the Advertisement and charged for. No displayed Advertisements can appear in above columns. Rates for Displayed Advertisements are as follows:—

For advertisements on inside pages, except page facing leader, for less than a quarter-page; per inch single column—

1	6	13	26	52 insertions
7s. 0d.	6s. 6d.	6s. 0d.	5s. 6d.	5s. 0d. each.

Per Column.—

Quarter-page	2 10	2 5	2 0	1 15	1 10 ,,

Back Page, £10 10s. A few dates open during 1900.

ORDINARY ADVERTISEMENTS.

	£ s.
Thirty Words	2 6
Every Additional Eight Words	0 6

Front Page, Five Shillings for the first 40 words, afterwards 9d. per line. Displayed Advertisements, 10s. 6d. per inch. Paragraph Advertisements, One Shilling per line. No Front Page or Paragraph Advertisement inserted for less than Five Shillings.

All Advertisements must be prepaid, and in cases where the amount sent exceeds One Shilling, the Publisher would be grateful if a P.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.'s.

Advertisements *must* reach the Office by 1 p.m. on Wednesday to insure insertion in the following Friday's number.

For the convenience of advertisers, replies to advertisements (except those in the Exchange and Sale Columns) may be addressed to "——," care of the ENGLISH MECHANIC Office, and will be forwarded by post to the advertiser, for an extra fee of Sixpence per insertion over and above the cost of the advertisement.

All Cheques and Post-Office Orders to be made payable to THE STRAND NEWSPAPER COMPANY, LIMITED, and all communications respecting Advertisements should be distinctly addressed to:—

THE PUBLISHER,
THE "ENGLISH MECHANIC,"
332, STRAND, LONDON, W.C.

This is necessary, as there are several papers published at the same address, and unless letters are fully directed, it is impossible to tell for which paper they are intended.

For Exchange.

The charge for Advertisements in this column is 6d. for the first 16 words, and 6d. every succeeding Eight, which must be prepaid.

SPECIAL NOTICE.—*Correspondents are strongly recommended not to send money or goods to strangers. The safest way when dealing with unknown advertisers is to send a Post Office Order made payable —— days after date, when in case of non-arrival of goods, or dissatisfaction, payment can be stopped.*

Telescope. Calver 8½in., finder, eight eyepieces. Wanted, good light Brass-finisher's Lathe.—BANKS, Corporation-street, Bolton.

Muller's **Alpha Gas-making Machine,** for 30 lights, in working order, £20, or exchange a good 5½ Screwcutting Foot Lathe and Tools.—SUTTON, Navigation, Whittle, Chorley.

AND WORLD OF SCIENCE AND ART.

FRIDAY, FEBRUARY 2, 1900.

A SMALL MOTOR-CAR, AND HOW TO BUILD IT.—V.

FIG. 14 shows two sectional views of the piston at right angles to each other. The grooves for the piston-rings are not to be cast in, but turned from the solid. The core-box is made exactly the same shape and size as the interior of the casting, allowing

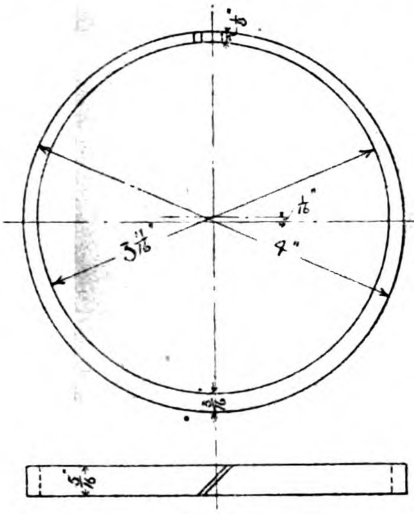

FIG. 15.

for shrinkage, and provision being made for the print, which should be rather long to balance the core—say about 4in. The bosses for the gudgeon-pin are put in the core-box, one in either half. To facilitate turning the piston, cast a boss on the centre of the closed end about 1¼in. diameter and 1in. long. The piston should be cast from the same metal as the cylinder, and blow-holes should not be tolerated. Should they be seen in the casting, refuse it, and have another.

To machine this casting grip it in a chuck by the boss on the back end, and turn the outside true, making it such a fit in the cylinder that it can be just pushed through the bore by hand. Take care to make the piston the same diameter all along, as if turned taper it will knock, and may score the interior of the cylinder. Before removing it from the lathe face off each end, the back to be faced down as far as possible. The grooves for the piston-rings are also turned in at this setting. Scribe a light circle around the piston, on which to mark off the centres of the holes for the gudgeon-pin. These centres can be marked off in the lathe if the headstock is fitted with a dividing-plate; or the gear-wheel on the mandrel, if an even number of teeth, can be used as a dividing plate if some kind of stop is rigged up. Whether marked off in the lathe or on vee-blocks on the surface-plate with the scribing block, great care must be taken to insure the hole being in the centre of the bosses cast on the inside of the piston. Another point which must be looked to is to get the gudgeon-pin *exactly* square with the sides of the piston.

The gudgeon or piston pin is to be made of mild steel, quite straight and parallel. Turn it to such a size that it will just require light driving with a mallet to get it into the holes bored for it in the piston, reamering the holes if required. To prevent it rotating in the piston, drill, tap, and countersink a hole for a ¼in. vee'd head set-screw, the screw to be half in one end of the pin and half in the piston body. After this screw is fitted, the gudgeon should be case-hardened. See that the ends of the gudgeon and the head of the screw do not project beyond the piston body. They should be rounded to the same curve as the outside of the piston.

The piston rings, of which we require three, with one or two over in case of breaking one, are of cast iron or mild steel, as preferred. Figs. 15 shows one of the rings when pinched together, ready for putting in the cylinder. Cast iron is the preferable material, but it requires rather careful handling in making and putting in, being brittle. The rings are first turned up roughly to 4⅛in. diameter outside and 3⅜in. diameter inside, and cut off to the required width. They should fit the grooves rather easily to avoid their binding. They are at this stage concentric. A piece ⅜in. wide is now cut out of each

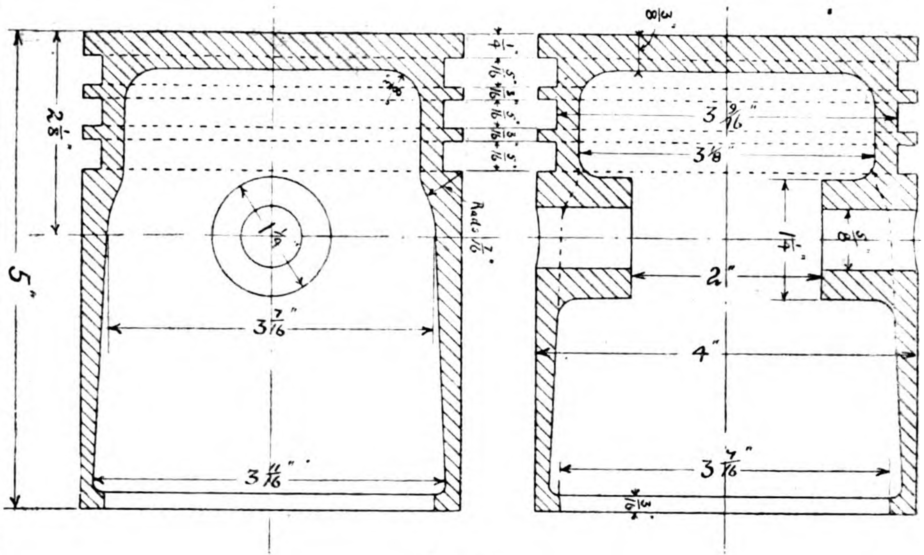

FIG. 14.

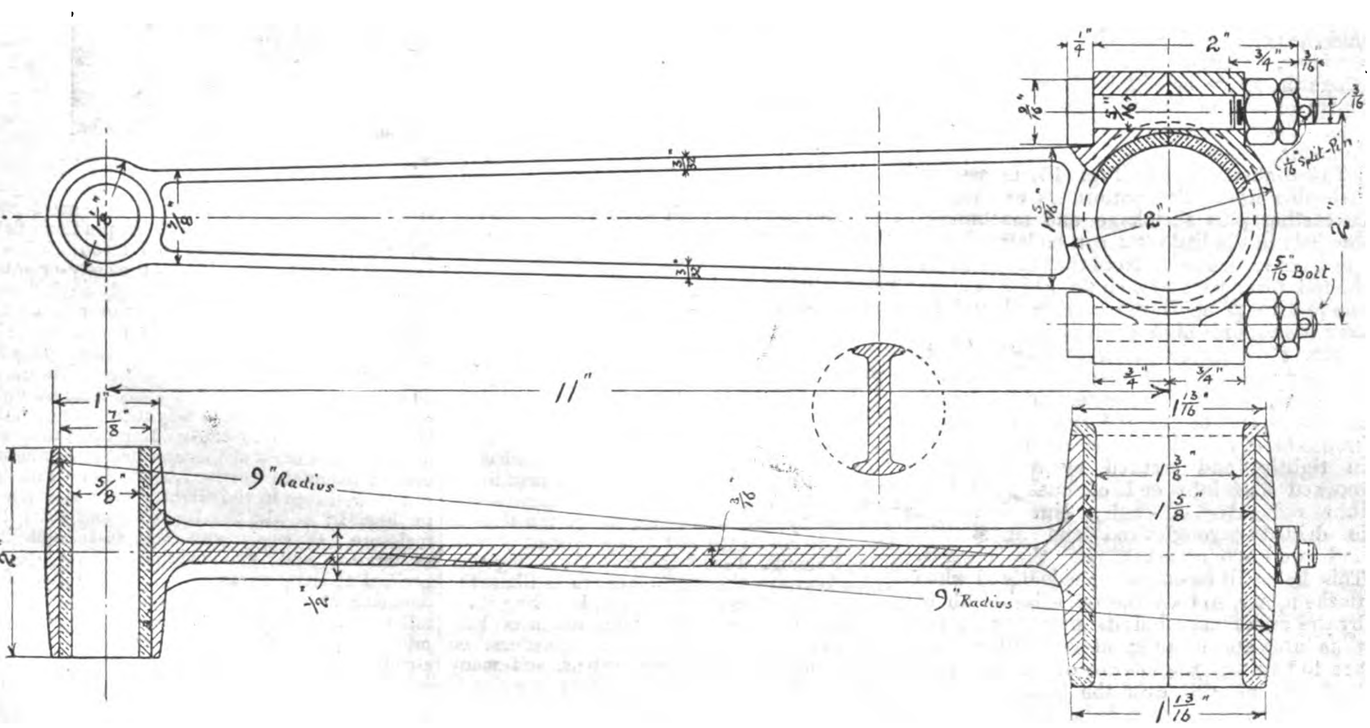

FIG. 16.

ring at an angle, and the ring sprung in and held by a band around it (or even a piece of copper binding wire), so that the joint is only 1/32in. open. They are now all three placed on a face-plate, which has been faced up quite flat and true, and clipped by means of bolts and plates by their edges in such a position that when turned up outside they will be of the exact dimensions given in Fig. 15. When set so as to hold up to size, the clips should be tightened down as much as possible, when the bands or binding wire can be removed. The outsides are now turned exactly 4in. diameter, and should be quite smooth. Turning all the rings at once insures their being all the same size. When the outside of the rings are turned take them off the face-plate, and make a chuck from a piece of cast-iron or brass, turning it out inside to 4in. diameter by ¼in. deep. Place the rings in this one at a time, springing them in, a small screw projecting into the joint serving to prevent them rotating, and locating the joint in the same place every time. This chuck, which should be bolted to the face-plate, is used 1/16in. out of centre, so that the rings are eccentric, as seen in Fig. 15. Note

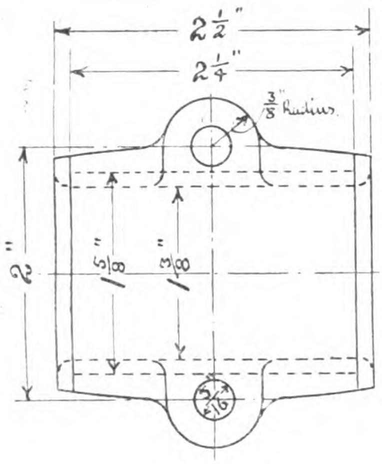

FIG. 17.

that the thinner side of the rings occurs at the joint. Therefore, this part of the chuck where the screw is will be 1/16in. nearer the centre of the face-plate than the opposite side. The insides are now turned to 3 1/16in. diameter.

The connecting-rod (Fig. 16) is cast in malleable iron. The pattern is exactly as its casting plus shrinkage and machining. The hole in the little end can be left solid or cored out as desired. Note that the edges of the rod form part of a circle, which enables one to turn it up if the casting should be very rough, or if high finish is required.

Fig. 17 is an end view of the big end, giving dimensions and shape of the lugs for the bolts, which are omitted in this view. The little end of the rod has a phosphor-bronze bush ⅛in. thick (see section), driven in tightly, and secured by a ⅛in. pin, screwed half into end of bush and half into rod. An oil-hole, ⅛in. diameter, is drilled through rod end and bush, and well countersunk on the outside. This hole will be on the top side of rod when in the motor, so that the oil splashed about by the crank may find its way into it, and thus lubricate the gudgeon pin. Oil-grooves are to be cut in the interior of bush so as to lead the oil well over the bearing. They need not be more than 1/32in. full in depth. The cap is first fitted to the big end, and the bolts made a good fit to the holes. The bolts should be turned and the holes reamered. The rod is now secured to the face-plate of the lathe, and the big end bored out for the brasses to 1⅝in. diameter. A gap-bed lathe will be required for this job. The holes bored in both big and little ends must be absolutely parallel with each other, and out of winding. Should they be in winding, if not to any great extent, the rod can be set; but it must be done cold, as malleable cast iron is hot short, and apt to fly.

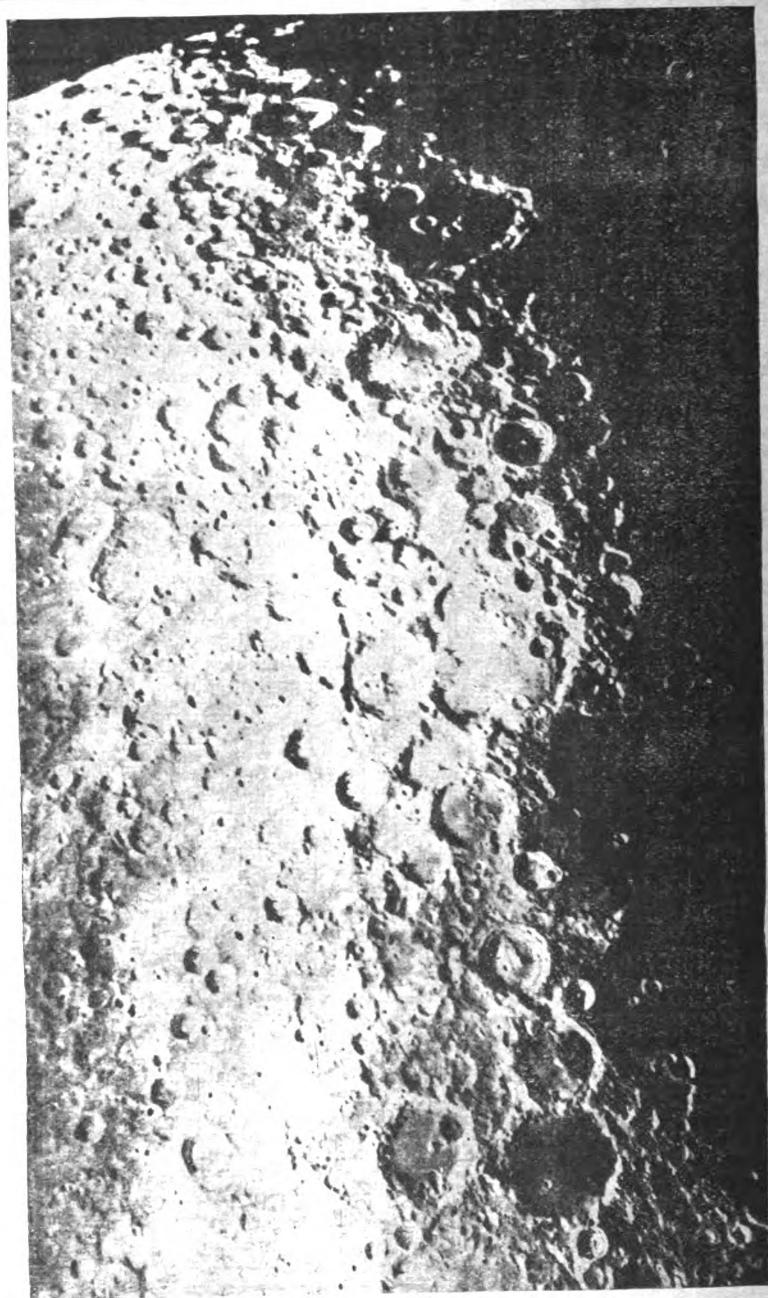

FIG. 1.—Maginus, Tycho, Arzachel, Alphonsus, and Ptolemaus. Moon's Age, 8½ days.

THROUGH A SMALL TELESCOPE.—VII.

By NORMAN LATTEY.

WE will now proceed to examine what is, perhaps, the most attractive meridional zone of the visible portion of the moon—that occupied by the terminator about the time of first quarter. In the last article a general view of the illuminated semi-disc was given, together with a key-map thereto, in order to facilitate the identification of its chief features, including those beginning to struggle out of the darkness along the broken edge. The latter formations, on account of their grandeur, extent, and many intricacies, need at least two papers in which to attempt their description. They might well be accorded several, and yet leave many interesting objects unnoticed.

Referring to Fig. 1 (an enlargement of a photograph with as many details filled in at the telescope as it was possible to insert) a pair of deep crater cups, the rim of the lower right-hand one almost encroaching on its companion, will be seen close to the South Pole at the top of the picture. These are Moretus and Gruemberger, two magnificent walled plains of great apparent ellipticity owing to their positions near the foreshortened limb of the moon. We are now in a wonderful region of closely-crowded craters with lofty borders and deeply-sunk floors, on several of which no ray of light ever falls; for neither the sun nor the earth can be even glimpsed from their gloomy recesses. This is, however, not the case with either Moretus or Gruemberger, although their finely-terraced walls overlook their interiors to heights reaching, in the latter instance, to 20,000ft. Moretus, the larger and most southerly of the two, has a magnificent central mountain nearly 7,000ft. in height. It can be well seen in the slightly later view given in Fig. 2; as also the beautiful and extensive inclosure, Clavius, with its vast encircling mountains, and two conspicuous ring-plains perched up on the north and south ramparts. The diameter of Clavius is, roughly speaking, 150 miles, and it embraces an area of 16,000 square miles, or rather over that of Denmark. The two striking ring-plains on the walls are scarcely more than 25 miles across, but their little central hills are easily observable at this period. The floor of Clavius is almost completely traversed from west to east by a chain of five craters, diminishing in size from the largest at the western end (lying almost midway between the two ring-plains already referred to) to the smallest under the eastern wall. All around are scattered innumerable craterlets, depressions, and other details. The broad, massive border affords almost unlimited field for

exploration with its steep broken sides, transverse valleys, clefts, ridges, and many other features. Under a low sun, the long shadows cast by the loftier peaks are exceedingly striking, particularly when they stretch completely across the slightly convex interior.

Returning now to Fig. 1 (in which Clavius is plainly outlined in threads of tangled light against the inky background), we find Maginus, an inclosure of nearly equal extent to Clavius (and immediately below it). But Maginus is obviously an older formation, for many of its once sharply-defined features have become almost obliterated. Fragments of a lofty border, however, still remain, and in one place attain an altitude of 14,000ft.

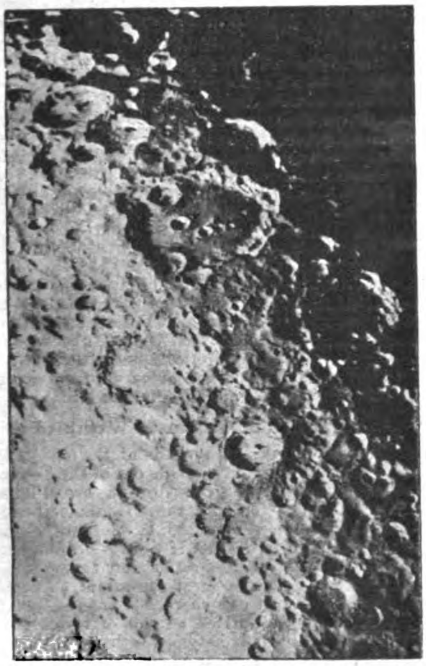

FIG. 2.—Tycho, Clavius, and Moretus. Moon's Age, 9 days 11 hours.

On the floor lie a group of little hills, and the eastern wall is occupied by several good-sized ring plains; but these, in keeping with the other remnants, wear the same appearance of demolition, their encircling walls being much broken, and here and there completely effaced. Curiously enough, Maginus is most difficult to detect under a high sun. The expression, "The full moon knows no Maginus," though not strictly accurate, has at times much justification.

Still further down towards the north stands Tycho, aptly styled the Lunar Metropolis. From this noble ring-mountain radiate those mysterious bright rays which at full moon are so plainly visible even to the naked eye, stretching like meridians of longitude far beyond the equatorial regions. Although but 54 miles in diameter, Tycho is a most conspicuous object, even amidst the scores of its almost equally striking compeers. Except under noonday illumination, the well defined terracing of its steep inner sides may be distinctly seen with so small an aperture as two inches. Along its towering ridges bristle innumerable peaks, and the massive border is everywhere traversed by valleys and depressions. Except for the fine central mountain, however, little has been noticed on the floor. Beneath the noonday sun Tycho exhibits the appearance of a deep saucer of purest chalk, shedding a snowy radiance all around, and shooting forth long streamers of silvery luminosity in every direction. But even the largest instruments are unable to discover the nature of these radiating rays.

Exactly beneath Tycho, though as far to the north as Clavius is to the south, will be noticed the comparatively small but conspicuous crater Hell, the principal irregularity on a vast low-walled ring-plain. It has a central mountain and many well-marked ridges. Abutting against the western section of the ridge surrounding the great circular plain will be observed another immense inclosure, Walter, 100 miles in diameter. Its floor is considerably depressed, and its borders much pitted. The central mountain throws a fine spire-like shadow at sunrise—which, by the way, is the best time to observe this interesting feature. Against the north west wall lies Regiomontanus; and encroaching on the northern rim of the latter, Purbach, with Thebit hard by, the two last forming together a well marked figure-of-eight. All of these are noteworthy objects with high surrounding walls, and contain much detail which space will not permit an elaborate description of.

We must hasten on to the striking trio of immense formations below, rendered more conspicuous by their contiguity and alignment. The smallest, Arzachel, just below Thebit, is a prominent ring plain some 66 miles in diameter, and encircled by a finely-terraced rampart completely surrounding the bright interior. In the centre stands a large central mountain with a deep crater slightly to the west of it (the latter can be plainly seen in the photograph). In Alpetragius, that well-defined object to the north-east of Arzachel, we have a formation which, though barely 30 miles in diameter, rears itself up in peaks 12,000ft. above the floor. It also possesses a central mountain, and the massive walls dividing it from its immediate neighbour to the north, Alphonsus, is well worth attention, especially under a low sun. But Alphonsus cannot boast of walls higher than 7,000ft. Its bright central peak and three dark patches on the floor deserve scrutiny, besides other interesting features in the way of clefts, ridges, and craterlets, most of which have unfortunately disappeared in the process of reproduction.

Abutting against Alphonsus is Ptolemaus, the most perfect example of the moon's walled plains. With it terminates the great meridional chain of lunar formations stretching in an almost unbroken line from the Equator to the South Pole. Ptolemaus could very nearly hold the whole of the north of England; but its border is much intersected by gaps and passes. On the floor of this extensive area can be discerned, under a low sun, a number of large saucer-shaped hollows with low rims. On the north-west side of the inclosure stands a bright crater, a few miles in diameter, and there are a few others which can be just detected in the photograph.

Close under the somewhat shattered northern wall of Alphonsus can be seen Herschel, a fine ring-plain with a lofty rim and prominent central mountain. Its inner slopes are splendidly terraced, and on the outside may be noticed irregular depressions. Many craters and valleys bestrew the rather dusky floor, and to the north lies the elevated plateau Herschel A, a region presenting many features for critical study.

With this *résumé* of the great ring-plains lying along the southern portion of the terminator at first quarter, our survey must come to a close. Next week we shall examine several of those magnificent formations which possess such startling terrestrial resemblances—viz., the vast chains of rugged mountains encircling the trackless wastes of the Mare Imbrium on the western side; likewise, a few of the great isolated ring-plains which, as regards their areas, and heights to which their borders rise, easily rival some of the noble circumvallations we have just been investigating.

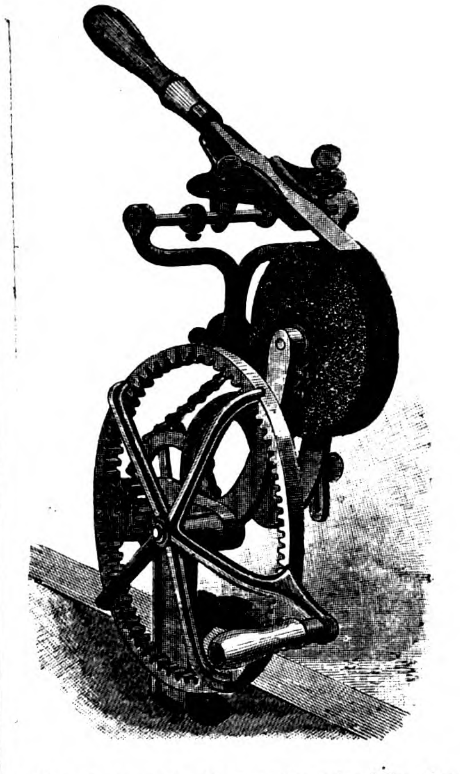
As before, the instrument in use was a 4in. Cooke refractor stopped down to 3in. It may be here mentioned that the stopping-down—which is accomplished by a piece of black cardboard (with a hole in it 3in. in diameter) placed over the object-glass—is done solely for the benefit of observers with small apertures. The light-grasp and separating power of the whole 4in. would, of course, reveal many details beyond the scope of the present series.

DILLENBECK'S TOOL-GRINDING MACHINE.

THE following description of a patent granted to Mr. Arie Van Dillenbeck, of 261, Hamilton-street, Albany, N.Y., for a tool-grinding machine, the novel features of which are found in the means provided for adjusting the table so that tools of various kinds can be sharpened with any desired bevel, is given in the *Scientific American*.

The machine is supported by a standard, the base of which is clamped to a shelf or bench. The standard has an arch at its upper end, and is provided with a rearwardly-extending horizontal arm at one side, and with forwardly and upwardly projecting arms at the other side. A stone is mounted in the fork formed by forwardly and upwardly projecting arms, and is connected by a chain and sprocket gear with a shaft mounted in the rearwardly-projecting arm at the upper end of the standard, and turned by an internal pinion meshing with a driving-wheel journalled in the horizontal arm at the base of the fork. By turning the driving-wheel the stone will be rapidly rotated.

The tool-holding table slides on a rod held between the arms of a fork, the shank of which is connected by a universal joint with a bar which is pivoted to one side of the arch, and which can be swung to raise or lower its outer end (and hence the table), and can be locked in adjusted position. Upon the table tool-holding clamps with under-cut bodies are mounted; these clamps can be adjusted to receive tools having short or long cutting edges, such as chisels, drawknives, and the like. In sharpening a tool the table is moved back and forth



on its rod, so as to sharpen all parts of the edge uniformly, collars being provided which limit the movement of the table, and prevent the tool from leaving the stone. By reason of the pivoted bar and the universal mounting of the table fork, the table can be raised or lowered to accommodate thick and thin tools, or moved to or from the stone to bring more or less edge of the tool on the grinding-surface, to produce a greater or lesser bevel. The machine can be driven with one hand, and the table manipulated with the other. As soon as the hand is removed from the table the weight of tool-handle will cause the table to drop back and carry the tool away from the stone.

LOCOMOTIVE ENGINE BOILERS.

A GLANCE at the past history of locomotive development shows that the increase in power has been mainly sought in enlarged cylinder capacity. Thus, cylinders 18in. by 26in., and even larger, have been fitted to boilers with 1,100ft. or 1,200ft. of heating surface, which at one time was considered none too much for 17in. by 24in. cylinders. The result has always been unsatisfactory. In more than one case it has been found necessary to line up the cylinders to much smaller dimensions before the engines could be got to keep time. Wiser counsels now prevail. Instead of seeking for shadowy economies by working with an early cut-off in a big cylinder, the designers of locomotives recognise the great truth that the first thing to be done is to cope with the traffic. That done, economy may be studied, but not before. There is a good excuse available for past policy and practice. It is that the designing of a narrow-gauge boiler with much more than 1,200sq. ft. of surface is full of difficulties, and that a big cylinder will take an engine up an incline which cannot be surmounted with a small one; but the latter theory is delusive. It has been fostered and supported by the great skill of a few exceptionally clever drivers, who understand precisely how to jockey an engine. In the hands of the great body of drivers the engine with big cylinders and a small boiler is a failure, and we believe that the larger number of locomotive superintendents in this country will now admit the truth of a statement long accepted as an axiom in

the United States and on the Continent—namely, that "a big boiler means going." No doubt we have fared better than our neighbours would have done, because of the generally excellent quality of our locomotive coal; but the limit has long since been reached, and more boiler power is being provided for heavier and yet heavier traffic demands.

It may be taken as proved that certain relations exist between the dimensions of a good locomotive and the work it has to do. These relations are lax, rough-and-ready, but still they do exist; and we venture to think that much might be gained if they were reduced to some approach to regularity of form and embodied in uniformity of practice. The resistance of a train weighing, say 100 tons, is about the same, under the same conditions of weather and gradient, on all the principal railways of the kingdom. It ought to be possible to say approximately how many square feet of heating surface ought to be provided to move 100 tons of train at, say, 50 miles an hour. We take this, of course, as the average speed on a fairly long run. We do not think that less than 700sq.ft. can be trusted to do this work with Midland coal, or perhaps 600ft. with Welsh coal. There is a theory that a big engine can do more work per foot of surface than a small one; so for 200-ton trains we find 1,400ft. regarded as too much for any coal. It seems to be forgotten that although it is possible—which we much doubt—that the big engine may be more efficient than the small foot for foot, that it weighs a great deal more. The weight increases in a very rapid proportion with the augmentation of the heating surface. Thus, the whole weight to be moved becomes more considerable. For example, while a 1,500-gallon tender would be quite enough for an engine with 600sq.ft. of heating-surface, a 3,000-gallon tender is provided to supply a boiler with 1,200ft. There is, then, we take it, every reason to believe that a fairly fixed relation exists between train loads and heating surface; and we shall find that this runs roughly at 600sq.ft. to the 100 tons. Thus, 300-ton trains ought not to be hauled by engines with less than 1,800sq.ft. of surface; as a rule now, they are hauled by two engines with 2,400 to 2,600sq.ft. between them. The wastefulness of piloting is so obvious that we shall not waste space by saying anything more about it.

When we come to consider the engine, another factor is introduced. We find, again, that practice gives us roughly a general relation between the size of driving-wheels and speeds. Thus, forty miles an hour are run with drivers anywhere between 5ft. and 6ft. in diameter; fifty miles an hour, with drivers between 6ft. and 7ft.; and sixty miles an hour and over, with 7ft. to 8ft. wheels. Again, very roughly, we have ten miles an hour for every foot in diameter of the driving-wheels. Given the speed in miles per hour, and the load, it is easy enough to settle for existing practice what the diameter of the cylinder should be. As a rule, we think the tendency of late years has been to give engines cylinders with too great a diameter. An engine with 18in. cylinders, 26in. stroke, 1,400sq.ft. of heating surface, 21sq.ft. of grate, and four coupled wheels 6ft. in diameter for a hilly road, and 6ft. 6in. for a level, would, it will be admitted, most thoroughly represent excellent proportions. Such an engine ought to be competent to deal with the very fastest and heaviest traffic handled in this country, some assistance being provided on steep inclines, such, for example, as Shap. But 1,400ft. of surface is the least that the boiler ought to have, and this should be good surface, or the result will be disappointing.

Now, this word "good" brings us to the very essence and point of this article. The efficiency of heating-surface varies through an enormous range. Let us take the case of an engine with 1,000ft. of heating-surface in tubes 10ft. long. Each foot in length of tube represents 100sq.ft. of surface. It is clear that by lengthening the boiler barrel 2ft. we can increase the heating-surface to 1,400sq.ft. But can it be argued that the extra 200ft. thus obtained will give aught but a small fraction more steam? Heating-surface in the smoke-box end of the boiler is not one-tenth as efficient as it is at the fire-box end, which brings us to the deduction that the right way to augment surface lies in increasing the diameter of the boiler barrel; and this is made admissible by keeping down the diameter of the driving-wheels to 6ft. or 6ft. 6in., without pitching the centre of gravity too high—no one ever yet heard of a locomotive upsetting so long as the rails did not sink, and it kept them? Thus more tubes—not longer tubes—are got into the boiler. But beyond all question it is in the enlargement of the firebox that increased steaming power should be sought. The firebox makes more steam than all the rest of the heating-surface put together; 1ft. in it is worth 10ft. and more elsewhere; and it is in the improvement of fireboxes that we must look for the development of locomotive power, rather than to anything else. Mr. Drummond, of the South-Western, has carried out a most successful experiment by putting in water tubes. These tubes, exposed to the full fury of the furnace gas, have been found, as we have already stated, to give no trouble whatever, while they greatly improve the steam-making power of the boiler. His success confirms the accuracy of statements made some time since in our pages in a series of papers on "The Marine Boiler of the Future." We therein said that if a water tube is not more than 24 diameters long it will give no trouble by bending or choking. Mr. Drummond's tubes are only about 16 diameters long. No doubt their success depends to some extent on the violent shaking which the water in a locomotive boiler undergoes. This rapidly disengages steam, and goes a good way to explain why locomotive boilers which do not prime when running, will if used for stationary purposes. A simple experiment will show what we mean. Nearly fill a bottle with boiling water, and cork it lightly. Then shake the bottle, and steam will be liberated and the cork blown out. A large grate should go with a large box. It is quite possible to get on with a small great provided the coal is very good. But it usually means a small blast pipe and heavy back pressure. Notwithstanding that a great deal of air is admitted nowadays though the fire-door, much has still to be pulled in through the grate, and a small grate always means a very heavy fire, through which the air rises with difficulty. Various forms of grate can be tried which give more air space than the normal flat English grate. Thus, there are step grates; then there is the basket grate; the grate with an air space of raised bars in the middle of its length; and so on. If we are content to set the grate on a considerable incline, it would seem that almost any length of bar can be fired, the motion of the engine shifting the coal down from the fire-door forward. Hitherto with hind-coupled engines it has been held that a long fire-box is impossible, because, in the first place, side rods are dangerous at high speeds; and because, in the second, coupled wheels will not run safely round small curves. Mr. Drummond, however, has the courage of his opinion, and he made an engine with side rods 10ft. long, which so far has refuted the accuracy of all prognostications of evil.—*The Engineer.*

CRUST-CREEP.

Geology and Its Practical Utility.

PROF. LAPWORTH'S opening address to the afternoon class in advanced geology, at Mason's University College, was devoted to the subject of the scientific and economic aspect of earth-crust movements in Southern Britain. After a reference to the course of lectures delivered last term, in which the mountain areas of Britain and Europe were treated of, he said that all the central parts of England were in reality an extension of the great so-called plain of Central Europe, not only as respects their geographical features, but also as respects their geological formations, and their geological history. Two great regions or systems of crust-creep,

The Scandinavian and the Armorican,

move in great wrinkles, or solid crust-waves, inwards upon it on its borders: the former from the north-west, the latter from the south and south-east. The Scandinavian creep ridges up into mountains and hills the western parts of our islands, as far as the eastern borders of wales; the Armoricain creep domes up the Weald of Surrey and Kent, forms the hills of Cornwall and Devon, &c., and meets the Scandinavian creep in South Wales to the north of the Bristol Channel. North of the English Midlands the long Pennine arch comes down from the Scottish border to Derby, forming the backbone of England. Wrapping round it follow in regular order the successive newer geological formations—the black sheet of the coal measures, and the red sheet of the Permian and Trias. As we proceed to the south follow the succeeding sheets of the Jura and the chalk, and the series is completed by the soft Tertiary rocks of the Valley of the Thames, which meet the Armoricain creep on the flanks of the weald. All these Midland rock-sheets are closed in rapidly to the west towards the borders of Wales, but they flatten and broaden out to the east as they sweep bulow the waters of the shallow North Sea to form the floor of the great plain of Central Europe. But while these Midland rock formations lie as a rule very gently inclined, and their study appeared to the geologist of fifty years ago to be comparatively simple, the mapping of the country in detail, and the discoveries of miners and geologists have brought to light hosts of unexpected difficulties, and at the same time have revealed wonders all unexpected by the earlier workers in the science. It might very naturally be supposed that as these Midland formations are so gently inclined, so, also, would be the rock formations which deeply underlie them; but of late years it has become clearly evident that these rest upon

A Wonderfully Rugged Subterranean Floor

of steep hill ranges and broad valleys. Now and again a peak or ridge shows through the flat-lying formations, as in Charnwood Forest and the Lickeys, or the old land is reached unexpectedly in boring for coal, as in the Eastern Counties. Not only so, but some old hill ranges have disappeared altogether, and nothing remains of them but the loose screes that were washed down their flanks. Again, long strain lines and bands of crust deformations sweep through our country. Along some of these bands the rocks have been warped and ridged up, along others they have been shattered and flung down hundreds, and it may be thousands, of feet, along others pushed for long distances over thrust plains, as in mountain regions. To one set of strain lines belong the great boundary faults of our South Staffordshire coalfield—the ranges of Dudley and the lower Lickey Hills. Another set is that which sweeps down from the western edge of the Pennine Chain, past the Wrekin and Caer Caradoc, Horderley, and Old Radnor, probably to the Bristol Channel. Twenty years ago the geologist saw few or no suggestions of law or rule in complexities such as these; but year by year, as the evidences accumulate, we find that the facts begin to arrange themselves. We have passed the day when we were content to name the ridges and the fracture lines after every individual place where we find them, or to speak of them as if their direction in space and the period of time of their formation were one and the same. We find that in space our great lines of warping and folding in Britain, as all the world over, can ultimately be all referred, like the lines on a geographical map, to four different axial trends or directions: One (like the Malverns) parallel to the lines of longitude; one (like the Wealden) parallel to the lines of latitude; one diagonal (like the Caledonian ridge of the Scottish Highlands) trending to the north-east; and another diagonal (like the so-called Charnian Rocks of Charnwood Forest) trending to the north-west. We see that the great systems of crust-creep—like the Armoricain and Caledonian—which sweep in long bow-like curves from one of these trends to another, wrinkle up the land,

As the Skin of Cream is Wrinkled

up in front of the skimming-ladle of the milkmaid. Nor is there any sign that a single one of the ancient crust movements, or the creep on the strain lines, has come to rest; for both the Scandinavian and the Charnian creep seem to have been almost equally concerned in the last Hereford-Birmingham earthquake. All the discoveries and theories, old and new, have also a most important economic bearing, for here, as elsewhere, the pure science of to-day becomes the applied science of to-morrow. To an ancient struggle between a then weakening Scandinavian and a growing Armoricain crust movement we owe our rich coalfields and coal seams, which were laid down largely in the shallow seas, the lagoons, and the lakes that were formed as the struggle progressed. The slowly-sinking hollows formed broad and quiet receptacles for deposition, and the rising lands afforded space for the abundant growth of vegetation to be swept into the quiet waters by rain and by rivers, while from the more rapidly-rising ridges came the thick wash of sand and clay, in which the coal seams were effectually sealed up and preserved for the use of mankind. As our knowledge is added to day by day by every new coalshaft and every new geological discovery, the phenomena of the crust-creep in coal measure times become clearer, and we infer, with closer and closer approximation to the truth, the ground where rich coal seams now lie below the red rocks of the country, and learn to avoid the ground where they have always been absent, or have been washed away by the elements. As our store of facts accumulates respecting the laws of crust movement, we approach nearer and nearer to that day when the land-owners, the mine-owners, and the speculators shall be freed from their present well-justified dread of proving the boundary faults of our coalfields, and will pierce confidently through them at the safest and the cheapest spots, and open up for working the now-hidden coalfields outside them, thus furnishing employment, comfort, and it may be riches, to the coming generations.

A COMPREHENSIVE REFORM.

ACCORDING to *Engineering*, Mr. George Westinghouse has written a letter to a New York paper which is big with promise of better things for the dwellers in cities. As is well known, the extension of electric traction in New York, as in so many other cities of the United States, is leading to the erection of vast power-houses, in which steam-engines of enormous capacity are the prime movers. Mr. Westinghouse warns his brother engineers that this procedure is a mistake, and ought to be, if it is not, obsolete. By one blow he promises to demolish the difficulties that beset the path of the municipal engineer, and, whilst disposing of refuse, will solve the water problem, abolish smoke, and supply power for rapid transit. His plan is as follows:—"There are," he says, "created daily in New York about 500 tons of garbage, or at the rate of about ½lb. *per capita*. Such garbage is about 20 per cent. carbon and 80 per cent. water. By a process well demonstrated on a small scale, which is being

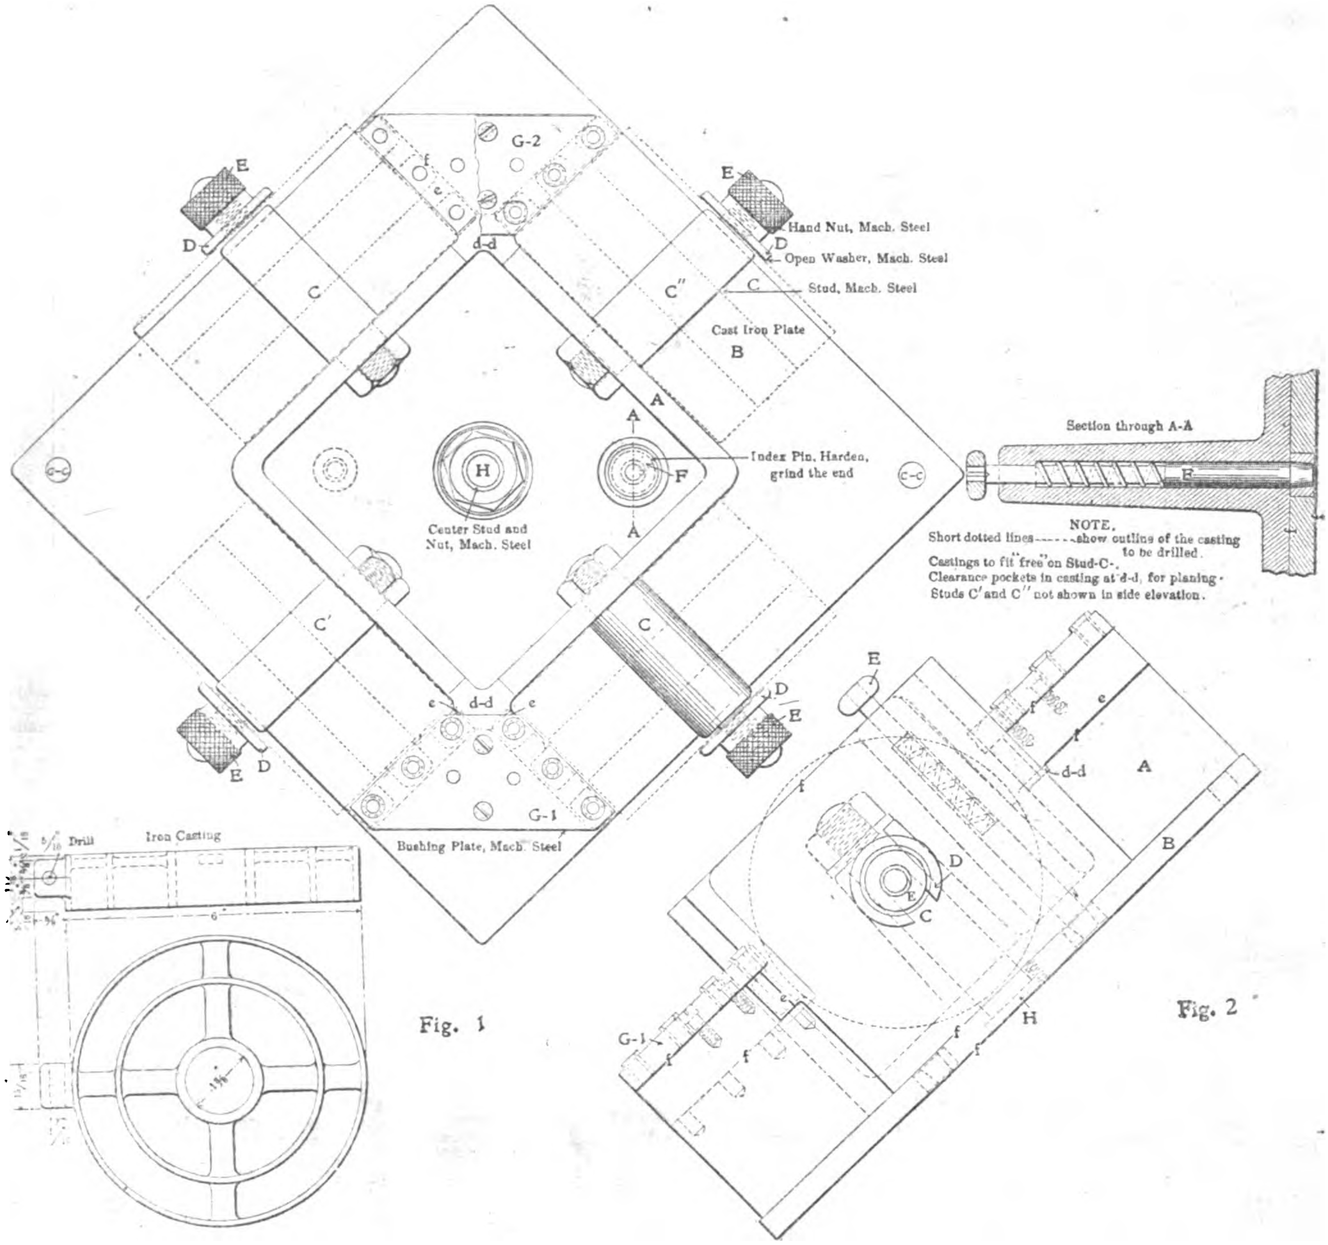


Fig. 1

Fig. 2

rapidly brought to a commercial basis, all of this garbage can be economically, and without offensive odour, converted into a fuel gas of great value. In the same apparatus, and by the same process, soft coal can be made into a gas suitable for power and heating purposes." The gas thus produced is to be used for operating gas-engines, which in turn will drive electric generators, the current produced being used for lighting or power purposes. Refrigerating water for the gas-engines will be taken from and returned to the river. This will relieve the town water of the duty of feeding boilers, and as it is estimated 20 per cent. of the water supply is used for generating steam, the growing difficulty of water service in New York will be pushed into the background. The name of Westinghouse is one to conjure with. More than once already the great American engineer has shown the way to higher planes of engineering enterprise, and, whilst at first derided, has at last proved himself triumphantly right. His present suggestions are fascinating from their boldness and heroic proportions. He bids the chief engineering authorities in his own country, the chosen land of progress, pause in their titanic scheme of laying down 375,000H.P. in steam-engines. "The plans," he says, "are based upon an imperfect knowledge of the subject;" they are "as far from the best as are the old cable systems for the propulsion of cars." Statements so positive, coming from an authority so high, cannot but cause any engineer to reconsider his position. We know already that by burning town's refuse steam can be raised, and it will be interesting to learn from Mr. Westinghouse quantitatively what the economic value of garbage is, used in the manner he proposes; what proportion of the one-fifth constituent of carbon in the garbage will be needed for the evaporation or dissociation, as the case may be, of the four-fifts of water; and also what percentage of soft coal is consumed in the apparatus. We have no doubt Mr. Westinghouse can give thoroughly convincing figures on the whole problem.

A DUPLEX DRILL JIG FOR A MULTIPLE-SPINDLE DRILLER.*

The accompanying drawing illustrates a tool recently designed by the writer, which may contain some points of interest to your readers.

Multiple-spindle drilling is usually confined to work of drilling several holes in each casting. The demand for many thousands of such castings as are shown in Fig. 1 brought forth the idea of drilling single holes in several castings at one time.

Fig. 2 is a top plan, shown in the position which it occupies on the drill-table, and an end view.

The cast-iron plate B is made 14in. square by ½in. thick, secured to the drill-table by two ½in. bolts at *c c*, and holds a centre-stud H, on which the jig casting B swings, and is held in two positions by the index-pin F. The casting B carries the studs C C C C, and the bushing-plates G_1 and G_2, and is not as complicated or difficult a piece to machine as may be inferred by a first glance at the sketch. The top and bottom surfaces were finished in the lathe centres in an arbour through the centre hub. *d d* are pockets for clearance of the planer tool in finishing the steps *e e e e*. The piece to be drilled is a light iron casting used in electrical work, and has no finish on the outside. Referring to the drawing Fig. 2, the pieces are slipped over the studs C C C C, and under the bushing-plates, resting on the steps of jig casting, as shown by short dotted lines, being held in place by the washer D and knurled nut E; the drill spindles are set for the six bushings at the back of the fixture G_2, the power-feed turned on, when the drilling commences, feeding through the 1⅝ths of metal in 55 seconds, during which time the operator places six more castings. The drill-feed releases automatically, the workman swings the fixture a half-turn, again snaps in his feed-gear, and proceeds to remove the six drilled castings, replacing them by others, and using 40 seconds, giving him a rest of 15 seconds before the feed again releases. The nut E, being made smaller than the stud C, leaves only the open washer to be slipped off before removing the castings. The time required by the operator to swing and index the fixture for each lot of six castings is five seconds, leaving the reader a little problem in multiplication to give the working capacity of the tool. In actual operation we have handled 3,250 castings per day, allowing one hour out of the ten for drill-grinding, and the rest for the operator.

A few words may be added here relating to the construction of jigs and fixtures for use in multiple-spindle drilling.

Jig castings may be made very light, and require but little to hold them in place on the machine, owing to the fact that more than one drill cutting at one time forms a brace to keep the work firm. Again, where a piece is to be drilled with several holes, and the jig can be so constructed, the piece may be slipped into the jig against a fixed pin or block held by the hand until the drill starts to cut, when it is then held as securely as if clamped with straps and bolts.

* By D. E. MacCarthy, in the *American Machinist.*

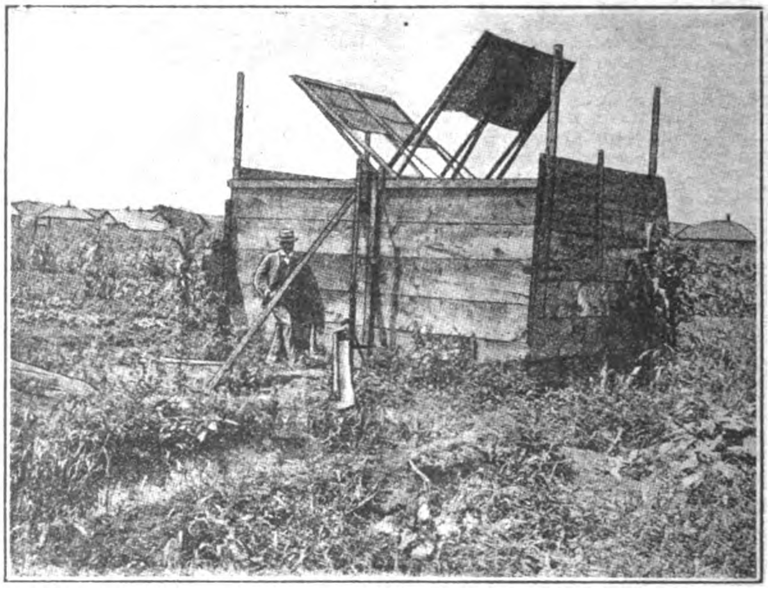
MOTIVE POWER, HIGH SPEED, AND STEAM TURBINES.

The Friday evening discourse at the Royal Institution last week was by the Hon. C. A. Parsons, and dealt with steam turbines, the coming method of propelling steam vessels. After a brief historical reference to the steam turbines described by Hero of Alexandria, and much later by Bianca, Mr. Parsons said that with the introduction of the dynamo the desirability of a high-speed engine was perceived, and the problem became to produce an ideal rotary engine. In 1884 experiments were begun for the construction of a steam turbine which was designed to run as slow, while the dynamo

went as fast, as possible in order to admit of direct coupling. Special bearings were devised for keeping down the vibration, and the turbine itself, which was 10H.P., making 18,000 revolutions a minute, consisted of 15 successive turbine wheels gradually increasing in size, to allow for the expansion of the steam. Defects were noticed, one being a tendency to whip in the spindle with accompanying loss of efficiency, but it was seen that these would decrease with increase in size, and therefore efforts were made to construct bigger engines. In 1888 several turbo-alternators were applied of 120H.P., non-condensing, running at nine or ten thousand revolutions a minute, and taking about 35lb. of steam per electrical horse-power, while in 1892 the adaptation of turbines of the radial flow type to work with condensers marked an epoch as regards economy in steam-power. Turbines of 2,000H.P. were now being constructed, still bigger ones being contemplated, and a large turbo-alternator recently tested was found at full load to consume only 18 8lb. of steam, 10° superheated, per kilowatt hour. Mr. Parsons said there seemed to be an important field for turbines to propel ships, as in such work lightness, careful balancing, and economy were required, and the 1892 turbines appeared capable of fulfilling these conditions. Their high speed, however, was a drawback, since it rendered direct coupling with an ordinary screw impossible. Experiments were, therefore, begun, and, economy suggesting a small boat, the *Turbinia* was built and fitted with engines of 2,000 actual horse-power. Many trials were made with various propellors, but the speed attained was disappointing owing to the excessive slip and inefficiency of the forms used. Mr. Parsons explained the "cavitation" phenomena which wasted the power, giving an ingenious experimental demonstration of the vortices formed in the water by the revolving screw, and pointing out that the best way to avoid them was to have a coarse pitch on the screw and a large blade area. The *Turbinia* was radically altered and fitted with new turbines. The alterations had a marvellous effect. The speed was doubled and 32¾ knots authenticated on the measured mile, while when the vessel was at the Naval Review it was estimated that 34½ were attained. There was but little vibration, and the engines worked very economically. After this success larger works were constructed at Wallsend-on-Tyne, and contracts entered into with the Admiralty for building a torpedo-boat destroyer with a displacement of 350 tons to have a speed of 31 knots. The engines were similar to those of the *Turbinia*, but there were two distinct sets working four screw-shafts, each of which carried two propellers. The two low-pressure turbines acted on the two inner shafts, which also carried the reversing turbines that enabled the vessel to go backwards. The boilers and auxiliary engines were as usual on such ships, and the destroyer, which was named the *Viper*, could be manœuvred like an ordinary twin-screw vessel. On her second trial trip, she attained a mean speed of 34·8 knots, her fastest trial being over 35 knots, or about 41 statute miles per hour, with an indicated horse-power of 11,000; the *Viper* was thus the fastest vessel afloat. After commenting on the great ratio of her steam expansion, the steam entering her high-pressure engines through an 8in. inlet, while it left the low-pressure turbines through an outlet 4ft. square, Mr. Parsons concluded by sketching a few types of vessel in which his turbines might be used. One was a cross-Channel boat, with a length of 270ft., a beam of 33ft., and a tonnage of 1,000. She would carry 600 passengers, and with engines of 18,000H P. attain a sea speed of 30 knots, against the 19 22 now reached. Another was a small unarmoured cruiser, with a length of 420ft., and a displacement of 2,800 tons. Provided with eight propellers and engines giving 80,000H P., she would be able, if necessary, to maintain a speed of 44 knots for eight hours.

HOME-MADE WINDMILLS.

THE illustrations annexed show two windmills, examples of those found in Nebraska, which are published by the *Scientific American* as specimens from a series of articles which are to appear, from the pen of Mr. E H Barbour, entitled "The Home-Made Windmills of Nebraska," in the Supplement. To those who may be unfamiliar with these windmills, says the *Scientific American*, they will be a revelation, and the importance of this movement, inaugurated by the inventive farmers of Nebraska, is made manifest, in that many acres of garden truck, fruit land, and even farm land, are irrigated at a trifling expense. Stock is supplied with water, ranchmen and sheep-herders are benefited, dairy products are increased and improved, and the comfort of the village and the rural home is often enhanced. The merits of these home-made mills have enjoyed such prompt recognition that they are going up daily, not to the detriment, however, of windmills which are made by regular manufacturers, but in addition to them. In a given community the man who puts up the first mill generally furnishes the model for the rest of the neighbourhood, hence it seems desirable that good models should be used, as illustrated in Mr. Barbour's paper. All of the leading types, are shown, and they may serve as models, and, with the aid of a few types, almost anyone can construct windmills which will prove of substantial benefit to their constructors. The author has visited a large number of mills in various parts of the State of Nebraska, and in other States, and his writings on the subject give proof of an intimate acquaintance with the subject.

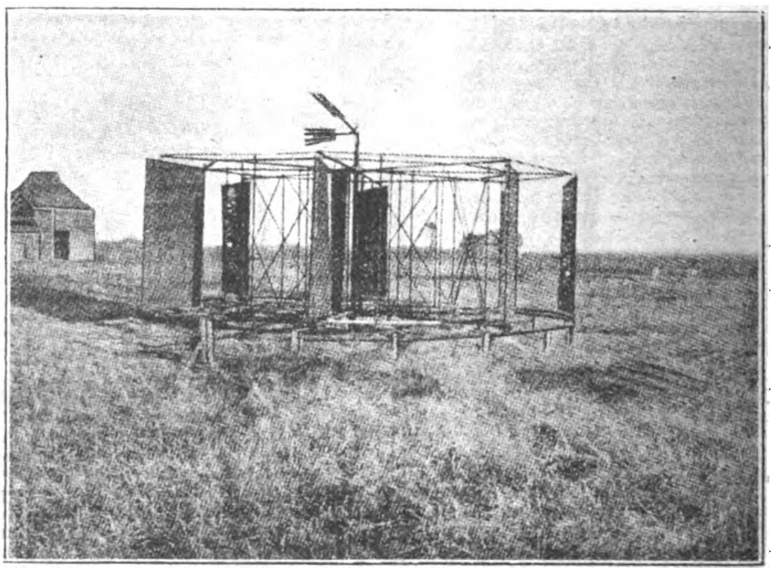


Home-Made "Jumbo" Windmill.

The builders of home-made mills in Nebraska are generally the wealthy and more progressive among the older and well-established farmers, or else younger men just making a start, and not the roving, unsettled, or shiftless class. Some of the beginners use the home-made mill for the irrigation of the garden and for supplying the house, and others make luxuries of them rather than necessities. They put them to work in various ways so save hand labour, such as running a grindstone, churning, working a feed-grinder, corn-sheller, the wood-saw, and other farm machinery. The cost of these windmills is not great. In dollars and cents the average mill will not fall far from four or five dollars, not including the labour. Such mills are usually put up at odd times, and made out of material at hand, such as old lumber, poles, and hardware common to every farm. Some builders, by a display of superior management, erect excellent mills at a nominal extra expense of one or two dollars for labour and hardware. Some mills will be found doing good service which cost but 1dol. 50c., and from this there is every gradation in the price of mills up to 150dol., which gives an efficiency of 8H P., and is capable of grinding food for the stock at the rate of 200 to 300 bushels of grain per day, according to the wind.

Mr. Barbour divides the mills into "Jumbos," "Merry-go-Rounds," "Battle-Ax," "Holland," and "Mock Turbines." This includes all of the main types of the home-made mills known at present.

The "Jumbo," or "Go-devil," as some call it, is very like an old-fashioned overshot wheel. They lend themselves readily to construction, being very simple in design, and they are very economical, owing to the fact that old lumber, laths, shingles, split rails, tin from old roofs, &c., can be pressed into service in the construction of these mills, and even the useful tin can unsoldered can be utilised for nailing on the loose sides of the Jumbo box. The efficiency of the Jumbo mills is low; but this is compensated for by the fact that they are comparatively inexpensive to build, for a good mill of this type can be built for 3dol., and a better one for 8dol. Some have been built large enough to irrigate 10 acres of orchard. The smaller Jumbos, termed "Baby Jumbos," are very small mills. They are generally mounted on abandoned towers or upon buildings, while the larger mills of the same class are set upon the ground and securely anchored there. They are all set so as to catch to best advantage the prevailing wind of the place, which is north and south in Nebraska.



A "Merry-Go-Round" Windmill.

The construction of the Jumbo mill will be understood by reference to our first engraving, which shows one which was made at an expense of 8dol. The sails are made of old coffee-sacks, and the cut-offs or wind-guards may be seen at either side. They are raised and lowered by pulley and rope. The dimensions are 13ft. long, 9ft. wide, and 13ft.

high. This mill successfully irrigates a five-acre garden. The reservoir supplied by this mill is 150ft. long by 4ft. wide, and 2ft. or 3ft. deep. The sliding doors may be raised or lowered, so as to cut off more or less of the force of the wind from the fans, as is rendered necessary by winds of varying velocities. Sometimes these Jumbo windmills are built one north and south and the other east and west, so as to insure service, whatever the direction of the wind.

In the "Merry-go-round" mill is found another attempt at the construction of mills of unlimited size. These mills are rather complex in construction, and are not put up by the farmer, but by a carpenter, and at a considerable expense. Mounted upon towers, like ordinary turbine mills of the manufacturer, they soon reach a size at which the wind can upset them, however well anchored. This has led to the towerless mills which stand low upon the ground, and consequently are capable of a greater circumference. These mills consist of a number of fans revolving about a central axis. About the same axis usually revolves a semicircular hood, thus exposing half of the fans, and shielding the other half, the shield running upon friction rollers. When the mills are to be thrown into gear the cord simply revolves until it covers all the fans on the windward side. Small and medium sized mills may be constructed in this way. A larger Merry-go-round is that built by S. S. Videtto on a ranch near Lincoln, Neb.; it is shown in our engraving. This mill has a diameter of 40ft., and the fans are 12ft. to 14ft. high. The whole structure is carefully designed and well made, being solidly braced, and runs upon a circular steel rail. This is an experimental mill, and it is hoped that this, or some other equally powerful mill, may yet be perfected.

Mr. Barbour then goes on to describe turbines or open-faced mills, which include the "Battle Ax" mills, the "Holland," which resembles the well-known type used in Holland, and the "Mock Turbines," which resemble the manufactured article so closely as to be scarcely distinguishable at times. The subject is a most interesting one, with which all our great agricultural class should be acquainted.

A SIMPLE METHOD FOR PREPARING SALTED PAPER.

In the current number of the *Camera Obscura*, Franz Hofbauer describes the following simple method of preparing a matt-surface plain paper, which differs from most methods in that plain, and not boiled, arrowroot is used for the salting solution. Strong white paper is coated by means of a badger's-hair brush with a mixture of arrowroot (finely powdered) 10 grammes, salt 0·66 gramme, distilled water 33c.c., carbolic acid (pure) 6 drops. This mixture should be well shaken before use till the whole of the precipitate is suspended. The brush should be kept about half full of the mixture, and the paper brushed over in all directions, so as to obtain as even a coating as possible, and, finally, all marks evened out with the damp brush. Any streaks faintly visible after drying will not matter, as the important thing is not so much an even coating as an even damping of the paper. The paper should now be allowed to dry spontaneously, without heat, in a place protected from dust; it should be left to lie flat for 24 hours.

In order to sensitise this paper, the following solutions should be prepared:—(A) Silver nitrate 5 grammes, distilled water 25c.c.; (B) citric acid 5 grammes, distilled water 25c.c., carbolic acid (pure) 6 drops. Mix immediately before use just enough of these solutions by pouring one part of solution B into two parts of solution A. The paper should be supported at an angle of 45°, and fastened down at the corners by sealing-wax, and the sensitising solutions painted across it from left to right without pressure, so that the streaks of the liquid shall run into one another. Metal pins must not be used, nor should the brush be fastened with metal.

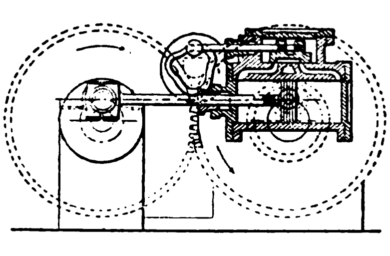
The sensitising solution will gradually become cloudy from the chloride and arrowroot taken up from the surface of the paper by the brush, but this is of no moment, if the brush be not dipped too far into the liquid so as to disturb any precipitate. Thick, rough papers as a rule require more coatings than thin, smooth ones, though a good deal depends upon the kind of paper. The sensitised paper should be allowed to dry spontaneously in a place free from dust, and, as a rule, paper sensitised at night will be ready for use the next day; it will keep longer, but better results are always obtained if it is used at once, and the freshly prepared paper is always slightly damp, which is in favour of the prints.

The finest prints are obtained from tolerably plucky negatives with the following platinum bath. The paper should not be much over-printed, and then washed for about half an hour in three changes of water and then treated with the following:—Potassium chloro-platinite, 1 gramme; distilled water, 300c.c.; nitric acid (pure), 20 drops. The prints will turn first reddish-brown, then violet-black, and finally black. Toning should only be carried to the violet-black stage, then washed and fixed in a 10 per cent. solution of hyposulphite of soda for a quarter of an hour, and then well washed and dried. Greyish-black tones are thus obtained. If toning is carried on too long, the whites become yellow.

If, when dry, the prints do not show a fine grey and the whites are yellow, they may be toned in the following bath: Ammonium sulphocyanide, 10 grammes; sodium phosphate, 12 grammes; distilled water, 250c.c.; solution chloride of gold (1 per cent.), 30c.c.—*British Journal of Photography.*

GAMBLE'S NOVEL ENGINE.

The following description of a novel engine which has been patented in the United States by Mr. H. E. Gamble, of Hoboken, Belgium, is given in the *American Machinist.* It is a "very novel engine, in which the crosshead and connecting-rod are done away with, and yet the engine is not of the oscillating type. The sketch shows the



arrangement, by which it will be seen that the cylinder, with its connected parts, revolves in the opposite direction from the crank-pin, and it is evident that if the cylinder and valve-chest could be made of the same weight as the piston and connecting-rod, the engine as a whole would be exactly balanced horizontally."

Minima of Algol.—Erratum.—We regret that, through an inadvertence, the times of Minima of Algol given on pp. 439 and 527 are exactly 12 hours too late. The reader is requested to subtract 12 hours from each of them in both cases.

USEFUL AND SCIENTIFIC NOTES.

Steel, as a shipbuilding material, was used in the United Kingdom during the past year to the extent of 93.8 per cent. The amount of iron used was only 1·2 per cent.

There is an outcry in Paris against the behaviour of the drivers of motor-carriages, who appear from all accounts to have a supreme disregard for all rules of the road. Some time ago officials were appointed to "keep an eye" on automobilists, but they do not seem to have met with much success, probably because they have to depend upon their limbs to catch the offenders. It seems likely that more rigorous steps will shortly be taken to limit the legal speed of these vehicles.

The beneficial effect of water filtration upon the typhoid death-rate of a community afflicted with polluted water is strikingly shown by figures given in the report of the Massachusetts State Board of Health for 1898. From 1887 to 1892, inclusive, the number of deaths from typhoid in the City of Lawrence ranged from 47 to 60 per annum, a rate per 10,000 of population of 11·44 to 13·44. The filter plant was put in operation in the latter part of 1893, and the typhoid deaths for that year fell to a total of 39 and a rate of 7·96 per 10,000. In 1894, the first full year the filter was in service, the deaths were 24, and the rate 4·75 per 10,000. There has been a steady diminution since, until in 1898 there were but eight deaths from typhoid fever in the city, giving a rate of 1·39 per 10,000 population.

Aerial Navigation.—In the current issue of *Feilden's Magazine*, some attention is given to the subject of aviation, which, it would appear, has retired to some extent from the prominent position which it occupied a few years ago. The great difficulty of assailing the Boers in their rocky strongholds has called attention again to the great desirability of some means, and which should be sufficiently effective, to enable the attacking party to reconnoitre the enemy's position. Ten years ago, the Americans, the Russians, the French, the Germans, and ourselves were experimenting with war balloons. No great success, however, attended these expensive experiments. Major Renard, a French engineer, was the only one who succeeded in navigating a balloon at all. On one occasion he succeeded in making the balloon travel about for a few miles, and then return to the starting point, but this was in a dead calm. After that no success was achieved.

SCIENTIFIC NEWS.

It appears that the solar haloes and parhelia observed from various parts in the southern counties on Jan. 11 were also seen from many parts of western France. M. de Fonvielle, in *Cosmos*, publishes a description. The "brilliant meteor in sunshine" of Jan. 9 is the subject of a note, accompanied by many reports, by "W. F. D." in *Nature* for Jan. 25. The meteor appears to have been observed in the southern counties only, and the writer of the article (evidently Mr. W. F. Denning) says that "the radiant point was probably at a rather low altitude in the S.W. sky."

Sir William Huggins has in the press a volume on the results obtained at the Tulse Hill Observatory, principally consisting of an atlas of star-spectra, with a rather full discussion of the evolutional order of the stars as indicated by laboratory examination of their spectra.

The density of close double stars is considered to be low as compared with that of the sun. There are two papers in the *Astrophysical Journal* by respectively Mr. A. Roberts, of Lovedale, South Africa, and Mr. H. N. Russel, of Princeton, U.S.A., in which the subject is examined mathematically. The authors obtain independently results which lead to the conclusion that variables of the Algol type are probably more than five or six times less dense than the sun.

The report of the Meteorological Council for the year ending March 31, 1899, has been issued. Forecasts are prepared three times a day, those at 8.40 p.m. being for the newspapers of the next morning. For the whole area of these islands 55 per cent. of the forecasts are classed as a complete success, and 28 per cent. as a partial success. The highest percentage of success was 88 in the south of England, the lowest, 78, in the west of Scotland and in the south of Ireland. During the last ten years the only year with a higher percentage of success (complete and partial) was 1893, with 84 per cent. over the entire area of the United Kingdom. Hay harvest forecasts are sent free of charge to recipients selected by the various agricultural bodies. The telegrams were sent daily for a period of about five weeks, and 89 per cent. of the forecasts were useful. Storm signals are hoisted at 234 stations, of which 121 are in England and Wales, 70 in Scotland, 31 in Ireland, four in the Isle of Man, and three in the Channel Islands. The report shows that 87 per cent. were justified by subsequent gales of high winds, but there were five gales for which no storm warnings were issued.

The new wing of the engineering laboratory at Cambridge, erected by his widow in honour of Dr. John Hopkinson, is to be opened by Lord Kelvin to-day (Friday, Feb. 2).

On Friday next week Prof. J. Reynolds Green, Sc.D., is to give a discourse at the Royal Institution on "Symbiosis and Symbiotic Fermentation." The lectures on "Modern Astronomy," by Prof. H. H. Turner, Savilian Professor of Astronomy at Oxford, will be delivered on Thursdays, Feb. 8, 15, 22.

Dr. G. K. Gilbert, of the U.S. Geological Survey, has been elected president of the American Association for the Advancement of Science. Dr. G. M. Dawson, director of the Geological Survey of Canada, has been elected president of the Geological Society of America.

The death is announced of M. Marion, curator of the Natural History Museum at Versailles, who some years ago superintended scientific sea-dredging expeditions.

Mineralogists and geologists will regret to hear of the death of Mr. James R. Gregory, at the age of 68. He started life as an expert in gems; but subsequently devoted his time to mineralogy and geology. So long ago as 1867 he went to South Africa prospecting for minerals, and was remarkably successful. Mr. Gregory had a fine collection of meteorites.

At the annual meeting of the Bristol Naturalists' Society, the president, Prof. Lloyd Morgan, F.R.S., gave an address, in the course of which he referred to some experiments in protective mimicry—i.e., one organism resembling another escapes danger on account of its resemblance. He had kept young birds, and they found from painful experience that bees were unpleasant food, and, in consequence, they avoided the drone fly, which somewhat resembles the bee. Both these insects are banded with black and orange, an

ornamentation rather common in deleterious forms. On a slip of glass he placed some meal, the young chicks ran to it and enjoyed the food; on another slip of glass, ornamented on the under side with bands of orange and black, he placed some meal mixed with quinine, the chicks ran to it, but on tasting the mixture it was received with much shaking of heads, and not a bird would go near food on the orange and black slip of glass again, even after it was washed and pure meal placed upon it. He tried young birds with cinnabar caterpillars and wasps. Those which had experienced that the caterpillars were unpleasant, avoided the wasps. Other experiments proved young chicks 24 hours old could swim as well as young ducks; it was a regular hand-over-hand swimming, not only excitement. Even a young duck, on first entering the water, would probably experience, in the words of Wordsworth "A pleasant shock of mild surprise." If this experiment was tried before the down on the chick was dry, it was not a success, neither was it with a moor-hen.

In a memoir presented to the Paris Academy of Sciences, M. P. Villard describes his experiments connected with the discharge of electrified bodies and the formation of ozone. In ordinary air incandescent bodies may emit cathode rays comparable to the Lénard rays, but of very low voltage, which explains the power of discharging electrified bodies that is possessed by flames, incandescent bodies, and phosphorus, the production of ozone by flames, and sundry other phenomena.

In a communication on the "Birds of Bute and Arran," read before the Edinburgh Field Naturalists and Microscopical Society, Mr. Craig said that the smaller fauna were fairly well represented, but the only important discovery made was that of the "grasshopper warbler" (Acrocephalus nævius) in Bute. There does not seem to be any recorded instance of its previous occurrence in that island, but as it has been identified several times in Argyleshire, probably its presence has merely been overlooked. Another warbler of irregular distribution in Scotland is the Chiff-chaff (Phylloscopus collybita), which was heard in both islands.

In New York Zoological Park a gigantic cage is being erected in which birds will have an opportunity of flying about practically free. The structure is built of steel tubing, and is covered with wire netting. It is 152ft. long, 72ft. wide, and 55ft. high. It incloses three forest trees of considerable size, a pool of water 100ft. long, and plenty of shrubbery.

The Forum at Rome has been coverted into an open-air museum, as, besides the archæological objects, so many plants have been introduced that the botanist can also find something of interest.

M. Moissan has shown definitely that fluorine when free from hydrofluoric acid and moisture is incapable of acting upon perfectly clean and dry glass even after weeks of contact. If, however, the glass contains the merest trace of any organic matter, the fluorine will attack that, and, forming hydrofluoric acid, the glass is speedily corroded.

A great snowslip is reported from the Grampian mountain known as Craigmegachidh, near Kincraig railway-station in Badenoch. The hill attains an elevation of some 2,000ft., and for about 1,500ft. from its base is almost perpendicular. At the top of the sheer acclivity, in one of the scaurs formed by water torrents and snowslips, are precipitous rocks, from which other seams branch off before the slope recedes to the summit. At this point an immense mass of snow was drifted in by south-westerly gales during the late storm, and the base having become insecure in consequence of a strong thaw, the prodigious pile was projected over the precipices. Acquiring terrific momentum downwards, it carried everything to the bottom of the hill—fir-trees, rocks, and huge boulders, some of these latter believed to be nearly a ton weight, being propelled as much as 200 yards beyond the bottom of the hill, destroying in their progress some 40 yards of a deer fence running at right angles. The carcases of two deer have been discovered in the mass of wreckage. Enormous herds of deer were to be observed daily on the summit of the hill during the storm, and, as a favourite pass with the animals is contiguous to the edge of the precipices, it is probable that their movements gave the impulse to the avalanche. About forty years ago a heavy snowslip occurred at the same spot, and hundreds of old pine and other trees were swept down, with immense quantities of rock. The track is still visible, as new trees have not grown.

The experimental trials with an electrical train on the District Railway are reported to have, so far, given satisfaction. The portion of the line selected for the experiments is that between Earl's Court and High-street, Kensington—about a mile, with a steeper gradient than is found on any other part of the Inner Circle. The current, supplied by Belliss-Siemens motors at 500 volts, is conveyed in channel iron rails in which metal shoes slide, the running rails being quite independent, as, for a long time to come, both steam and electrical trains will be used. The experimental train has coaches slightly wider than the present rolling stock, with compartments and doors at the sides, except in the case of the two motor coaches, which, having large wheels, the floor-level is so raised that a gangway is adopted. These motor coaches weigh 50 tons, and the train being a "shuttle," there is a motor at each end. When the train goes round the "circle," only one motor-coach will be needed.

The main line of the West Jersey and Seashore Railway—the portion between Philadelphia and Atlantic City—is to be fitted with electro-pneumatic automatic block signals. It is about 59 miles in length, and at present is worked by the manual telegraph block system. The work is to be completed before heavy summer traffic begins. It will be remembered that it is on that portion of the Pennsylvania system which extends from Atlantic City to Camden that the fastest train in the world runs during the summer season (see p. 38, No. 1744, or p. 401, No. 1708.)

The ice-breaker placed on Lake Baikal recently forced her way through ice 18½in. in thickness for a distance of over 30 versts, at a speed of 14 versts an hour. A verst is 5·2 furlongs.

USEFUL AND SCIENTIFIC NOTES.

The metric system of weights and measures is allowed to be used in Russia now with the system at present in use.

Acetylene gas for railway-carriage lighting has been in use for some time in the United States on the Cornwall and Lebanon Railroad. The gas is compressed, and is carried in the tanks formerly used on the same cars for ordinary illuminating gas.

From the returns compiled by Lloyd's Register of Shipping, it appears that, excluding warships, there were 538 vessels of 1,306,751 tons gross, under construction in the United Kingdom at the close of the quarter ended Dec. 31 last. This total shows a reduction of 95,000 tons, compared with the same date in 1898. But during 1899, 726 vessels of 1,416,791 tons gross—viz., 714 steamers of 1,414,774 tons, and 12 sailing vessels of 2,017 tons, were launched in the United Kingdom. The warships launched at both Government and private yards amount to 35 of 168,590 tons displacement. The total output of the United Kingdom for the year was, therefore, 761 vessels of 1,585,381 tons.

A swing bridge operated by electricity has been erected across the River Charles in the United States and connects Boston and Charlestown. The bridge, with approaches, is 1,920ft. long and the width 100ft. The revolving central section is 240ft. long, and weighs 1,200 tons. When turning it is supported on 70 steel wheels, 26in. in diameter, which run on a track 54ft. diameter. The plant for operating this portion of the bridge is contained in a chamber below, and the motive mechanism consists of two 28H.P. motors placed outside the power-house, one on each side and above the circular track. They are connected to this by means of bevel gearing and vertical shafts, so as to equalise the moving power.

Insect Life.—The distribution of insects is affected by that of plants. In the semi-tropical parts of New South Wales there is a semi-tropical insect fauna, but where the semi-tropical vegetation has become extended beyond semi-tropical geographical limits, there are found also the usual semi-tropical insects. In several places insects found associated with some particular kind of plant in one locality will be met with upon some kindred form of vegetation in another. Thus the peculiar beetles living on the leaves of the Queensland bottle tree are found feeding on the currajong at Wagga Wagga, in New South Wales. The Australian insect fauna is estimated at 10,000 species, but it is believed that the actual number is considerably greater. Of these the greatest variety is to be found in New South Wales, the scientific collections formed in Sydney and elsewhere being of singular attractiveness and interest.

LETTERS TO THE EDITOR

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.]

All communications should be addressed to the EDITOR *of the* ENGLISH MECHANIC, *332, Strand, W.C.*

⁂ In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks; a vice from whence great inconveniences derive their original." —*Montaigne's Essays.*

THE CIVIL AND ASTRONOMICAL DAY.

[43262.]—The "curious mistake" to which the "Fellow of the Royal Astronomical Society" alludes (p. 534) certainly requires some explanation, because it has been made in all sorts of papers from the *Times* downwards, and even in the scientific papers. I suspect that a "news agency" has sent round a paragraph based on the fact announced in the second paragraph of the "Scientific News" (p. 490), and there has been some confusion. As everyone knows, however, the *Nautical Almanac* is, of necessity, prepared several years in advance. I suppose that for 1904 is now in preparation or going to press—and it may be that an alteration is being made. There certainly was some proposal for assimilating the astronomical and civil time, and if I recollect the date suggested was the beginning of the next century—Jan. 1, 1901. Is not the *Annuaire* of the Bureau des Longitudes the equivalent of our *Nautical Almanac*? That, it appears, now uses civil time. It would be of use if this matter were set forth in a definite manner by authority. Is civil time to be adopted, or are we to stand "As you were"? The newspapers are now so fully occupied with "war news" that there is little room for anything else, or some questions might have been printed; but may I ask why there should be any distinction between civil and astronomical time? For all ordinary purposes 12 midnight and 12 noon seem suitable divisions. Cannot it suit the astronomers to reckon midnight as the finish of a "day," or must it be noon? P. M.

THE LUNAR RAY SYSTEM.

[43263.]—Adverting to the suggestion of "Silverplume" (letter 43219, p. 511), that the theory which I have submitted is not new, I should be very glad if he can refer me to any book in which such a theory has been put forward. For thirty years past I have taken a great interest in lunar study, and have read everything on the subject that I could get hold of; but I have never come across a suggestion that the lunar rays may have been caused by deposition of the lunar atmosphere. The nearest approach to that idea seems to be the theory of Prof. Pickering, which is discussed in Elger's work on the "Moon." His theory, like mine, suggests the action of wind currents; but the deposited matter is assumed to be volcanic dust (pumice) ejected from small craters. All the conditions he mentions, such as the commencement of the streaks from numerous small craters on the rims of mountain rings, the spreading out of the streaks as they recede from the craters, their reinforcement when a new crater is reached, and the passage of the rays over ridges and plains alike, seem to apply with even greater force if we substitute atmospheric for volcanic deposit, and the suggestion that the bright streaks are formed between the lines of wind currents removes many of the objections that have been urged against the professor's theory.

But volcanic dust seems hardly sufficient to account for what we see. The rays are generally assumed to be the latest of the lunar formations; but I think it is very doubtful if the emission of dust from the craters was the last act of all on the lunar surface. The deposition of the atmosphere might have been. Moreover, the deposit is much more universal than is likely to have occurred from volcanic dust.

Inspection of a good photograph will show that the deposited matter extends in many cases far beyond each side of the rays, but that it is not so bright as on the rays. On each side of the rays there is a plainly-defined dark lane, which, I think, is the line of the main wind current which swept aside the depositing matter. The rays, I suggest, were formed by the concentration of the matter *between* the currents, and in many cases they are subdivided into narrow streaks by fainter dark lanes caused by weaker wind currents. Again, when the actual currents meet an obstruction, such as a crater or mountain, one would expect to find a heaping up and spreading out of the deposit, similar to drifted snow, and such drifting is very

plainly visible around craters, mountains, &c., on lunar photographs.

As regards the suggestion that during the long lunar days the sun's heat would melt the deposits all over the moon—this would doubtless be the case if anything like a terrestrial atmosphere still existed on the moon. But Prof. Langley, in dealing with this very question of heat on the moon, gives a graphic account of his own experiences on the high regions of the Sierra Nevadas, where any part of his person exposed to the sun was severely burned, yet at the same time he was shivering with cold, and everything around him was freezing, owing to the rarefied atmosphere and rapid radiation. If such is the case on the earth, it is very improbable that, in the almost airless condition of the moon, the heat would have any appreciable melting effect, except near the equator, or in some sheltered places where, as I have suggested, it *may* occur, and thus produce the slight atmospheric effects which some observers have noted.

Besides, it must be remembered that Very's 206° is an estimate only, and I think, having regard to the difficulty of securing any accurate result, Very would be the last person to claim that such an estimate should be used as a basis for an argument as if it were a proved fact.

"F.R.A.S." (No. 43244, p. 534) deals very tenderly with my omission to mention pressure as an essential in liquefying the terrestrial atmosphere, and I fancy I can see the humorous twinkle in his eye as he penned that paragraph. The exigencies of space compelled me to condense my remarks—perhaps at the cost of lucidity. What I meant to convey was, that intense cold alone, such as is assumed to prevail during the long lunar night, might be sufficient to cause precipitation of the lunar atmosphere;—not that we have to assume exactly the same conditions and results as in a laboratory experiment when liquefying our own atmospheric air.

In conclusion, I can only say that, in putting forward this theory, I have been animated solely by a sincere desire to assist in the solution of one of the most puzzling mysteries of the moon. **Mark.**

THE NUMBER OF STARS NOT INFINITE.

[43264.]—WITH reference to previous correspondence on this subject (see letter 42994, Nov. 10), the following extracts from Dr. Isaac Roberts's recently-published book of celestial photographs may be of interest to your readers.

Dr. Roberts asks the question: "Are the millions of stars and the numerous nebulosities which are now known to exist, limited in number and extent, and do they consequently indicate that the universe, of which the Solar System constitutes a part, is only one member of a greater stellar universe?" He then records the following remarkable facts:—

"(*a*) Eleven years ago, photographs of the great nebula in Andromeda were taken with the 20in. reflector, and exposures of the plates during intervals up to four hours, and upon some of them were depicted stars to the faintness of 17th and 18th magnitude, and nebulosity to an equal degree of faintness. The films of the plates obtainable in those days were less sensitive than those that have been available during the last five years, and during this period photographs of the nebula with exposures up to four hours have been taken with the 20in. reflector. No extensions of the nebulosity, however, nor increase in the number of stars can be seen on the later rapid plates than were depicted on the earlier slower ones, though the star images and the nebulosity have greater density on the later plates.

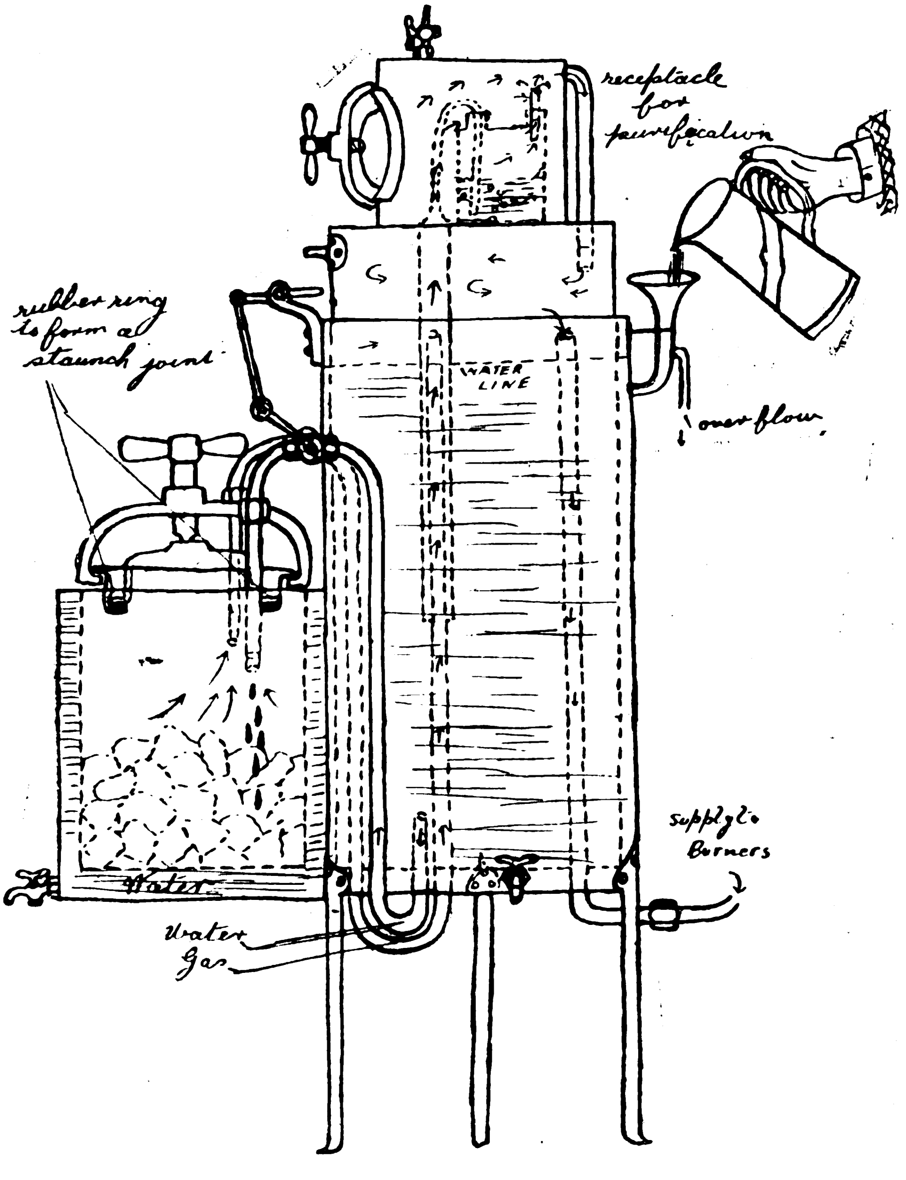
"(*b*) The great nebula in Orion has been photographed with the 20in. reflector at frequent intervals between the years 1886 and 1898, with exposures varying between one minute of time and 7h. 35m.; yet the stars are not more numerous, or the extensions of the nebulosity greater on the latter than are shown on a plate of like sensitiveness which had been exposed during 90 minutes only; the difference exhibited is that of density.

"(*c*) The group of the Pleiades has been photographed with the 20in. reflector at frequent intervals between 1886 and 1898, with exposures of between one minute and twelve hours. The results are that only the same faint stars and nebulosity seen upon plates, which have had an exposure of 1½ hours, are depicted upon those which have been exposed during ten to twelve hours.

"(*d*) Several photographs of the region of the Milky Way in Cygnus have been taken with the 20in. reflector between the years 1886 and 1898, and on comparing two of them (one with an exposure of 60m., and the other with 2h. 35m.) no fainter stars could be found on one than on the other.

Dr. Roberts thinks his evidence "may be accepted as demonstrations of the accuracy of the surmises of astronomers in the past, that the part of the starry universe visible from the earth is limited in extent."

The only remark I have to make on the above is that there appears to be no evidence whatever of the existence of the "greater stellar universe" to which Dr. Roberts refers. **Gavin J. Burns, B.Sc.**



JESSE'S ACETYLENE GENERATOR.

[43265.]—FOR the past few years I have taken great interest in the numerous designs of acetylene generators put upon the market by various firms, and of those made by amateurs which have been illustrated in this journal. I have made numbers of generators from these designs, and have come to the conclusion, after a lengthy trial, that my last effort has been most successful in every manner, and as I thought readers of this journal who are interested in this subject might be on the look-out for a generator perfectly safe and without a deal of complication, I have requested the editor to insert the following drawing, which readers may copy. The body of the gasometer and the generator itself are made of 20-g. zinc, which material acts admirably for this purpose. The series of levers at the side of gasometer actuate the water-feed as the floating portion of gasometer rises and falls.

Portsmouth. **S. Jesse.**

IS THE THEORY OF GRAVITATION A FINALITY?

[43266.]—MR. MUNRO (letter 43216) asks me for an authority for saying that it is not true that the theory of gravitation explains *all* the celestial motions. His next sentence, "True, we cannot explain by gravitation the rotation of the sun upon its axis, and that of the earth and the planets," supplies me with an authority. It surely cannot be the correct thing to say that a theory which explains a part explains the whole of the phenomena of the celestial movements. Would Mr. Munro have me say that because it explains some it explains them all? If so, then my ideas of logic and his are of a very different character. My critic does not appear to be aware that the moon's velocity varies in such a way as to attain its greatest speed when she is in syzygy (in opposition and conjunction), and her least speed when she is midway between these two points in her orbit (in quadrature). Nor does he seem acquainted with the fact that our great mathematicians are divided in opinion on so fundamental a point in the theory of the tides as the place which high water would occupy supposing the ocean to be vibrating with ideal tides. Newton, Laplace, and Airy held that low water should be represented under the moon and at the Antipodes, instead of high water as in modern textbooks.

So far from the tides having been thoroughly explained by the theory of gravitation, as Mr. Munro says, it is well known that the most conflicting accounts have been given by undoubted authorities respecting the *modus operandi* whereby this phenomenon is produced. (See remarks on the subject by "F.R.A.S." in the ENGLISH MECHANIC Aug. 3, 1894.) I am unable to follow Mr. Munro in what he says respecting the calculations of the eclipses and tides. The fact that these phenomena were calculated accurately by astronomers long before the theory of gravitation was invented ought to satisfy every reasonable person that the theory of gravitation can have nothing to do with these calculations. I am not aware that I said anything about the physical appearances of the heavenly bodies. I did, however, draw attention in my letter to their different physical constitutions, and to the fact that the sun acts upon the earth mechanically by means of his heat, and that in this respect there is a marked difference between the sun and the moon, since the latter is a source of no heat whatever to our earth.

I also said (and I challenge anyone to deny it) *that the theory of gravitation does not take into account these notable differences, but is based upon similarity only.* Surely everyone who knows anything of the subject must be aware that, according to gravitational philosophy, matter in general and heavenly bodies in particular are supposed to be inert, and the latter are said to act and react upon each other in a precisely similar manner by means of a precisely similar force called gravity. Now do the facts, viewed from the standpoint of observation and experience, strictly coincide with this theory? Is the sun inert in the same sense as the moon? Do the two bodies act upon the earth in an absolutely similar manner by means of an absolutely similar species of force or energy? These

are plain and simple questions which admit of the simplest answers possible.

The definition given of "attraction" by Mr. Munro as a movement of two bodies towards each other, is no doubt perfectly correct in the primary and ordinary sense of the term; but attraction in philosophy possesses another signification, for it not only denotes a movement of two bodies towards each other, but a movement of the same bodies away from one another. The sun is, in this sense, supposed to be constantly attracting the earth, notwithstanding the fact that the latter from perihelion to aphelion recedes from the sun. If the sun really attracted the earth in the ordinary sense of the word, it would continuously approach the sun in a spiral manner, instead of alternately approaching and receding from it. Sophistry in philosophy is not yet extinct. If it were, the science of logic would scarcely be required.

I am unable to endorse Mr. Munro's conclusion, "that if the theory of gravitation is not a finality it is not even an initiality." Many imperfect theories—the Ptolemaic, for example—have been extremely valuable in their time, although they have had to give way to more perfect theories. We are apt to underrate views that are obsolete, and to overrate established views in speculative science. The reformers of science have, in all ages, had to contend against those who think that they have attained to finality, and have, on that very account, been subjected to the unjust opprobrium of others who cannot appreciate the truly philosophical proverb of Solomon, "The wise will hear, and will increase in learning." I regard the theory of gravitation in much the same light as the Ptolemaic system—as a most valuable attempt to solve the problem of the causation of the celestial motions. But, at the same time, I do not regard it as a finality, because it does not embrace and explain the whole of the phenomena, and because it neglects to take into account the motor effects in the cosmos of those great natural agents of motion known as the correlated forces — viz., heat, magnetism, and electricity.

I believe that it will be a matter of surprise to a future generation that a theory of celestial dynamics which excluded the agency of heat, magnetism, and electricity from a share in the causation of the celestial motions, and which attributes these movements entirely to a unique force called gravity, should have retained its vitality throughout the 19th century. I hope "R. L." (43239) will pardon me for saying that I fail to see that his letter throws any light upon the subject.

It may serve to amuse the leisure time of lovers of romance to speculate about what may have happened "in the beginning," or about "the origin of motion," but such speculation can have nothing to do with things as they are. It would be as vain to speculate about the origin of matter itself, or of energy, both of which are held by modern physicists to be indestructible. I trust that any of your correspondents that may think fit to enter into the discussion will adhere to the main points. A decisive answer should be given first of all to the question, Is the theory of gravitation a full and final explanation of the mechanical and physical cause of the known movements of the Solar System? And if the answer is in the negative, the queries obviously follow, What is the nature of the defect in the current theory?—Have any new facts come to light in astronomy and general physics since the theory was formulated? Until these questions are definitely answered, it would be useless to discuss any novel theory.

Hugh Alexander.

PROPORTIONS OF TELESCOPES.

[43267.]—THE reply of "F.R.A.S.," that the focal length of a lens should be about fourteen times its diameter, scarcely touches the real question. This well-known proportion, it seems to me, is merely the limit prescribed by the difficulty of working lenses of shorter focus with sufficient accuracy to prevent the imperfectly-corrected aberrations becoming obtrusive.

Optically there seems no such limit as this 14-to-1 proportion. On the other hand, I believe it is generally admitted that, *cæteris paribus*, of two telescopes, the shorter will give the more brilliant image. Herschel long ago suggested that perhaps in seeking improvement by lengthening the focus, we in reality might be going in the wrong direction, owing to other conditions interfering with the results.

In a Gregorian or Cassegrain we get an equivalent focus of, say, 250in., though the actual length of the ray-paths may not exceed one-sixth of this distance. Is there, then, any "real best" proportion, so as to combine a maximum of brilliancy with a maximum of focal length, assuming that the question of imperfect workmanship is ignored?

A. S. L.

CUTTING WHEELS WITH PRIME NUMBERS OF TEETH.

[43268.]—REQUIRING a number of small toothed wheels for a geometric curve arrangement, it was necessary to find some means for cutting those which had numbers of teeth only divisible by unity—prime numbers—the others presenting no particular difficulty. It must be admitted in the beginning that there is no way of cutting a wheel, say, of 37 teeth with precise theoretical accuracy; but the method I am about to describe will be so near, that all practical purposes are answered.

My lathe, which is by Cooke and Sons, of York,

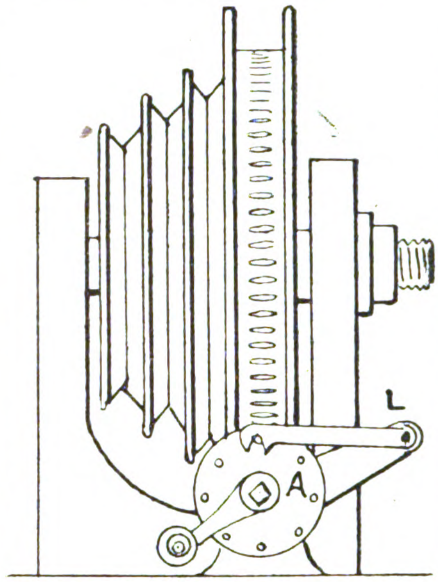


FIG. 1.

has a worm-wheel and tangent-screw attached to the headstock in the usual way. The worm-wheel has 180 teeth, and the spindle of the tangent-screw can be fitted with discs divided in any desired way, and perforated with holes for the reception of a pin which is held in place by a notched lever coming down on it, as shown in Fig. 1, L.

The essential parts for the purpose of cutting prime wheels are shown in Fig. 2, where A represents a gunmetal wheel fixed on the end of the tangent screw, and perforated with 100 equidistant holes. B is a piece of metal fitted with two pins C and D, which are exactly the distance of 10 holes apart. Any other number might be taken, as these pins are only to hold the piece B to the division-plate A. It may be mentioned that the pin C projects outwards so as to form a handle, and it is also longer on the other side, so as to facilitate adjustment, the long tapered end being placed in the desired hole, when the shorter pin D easily slips into its own place.

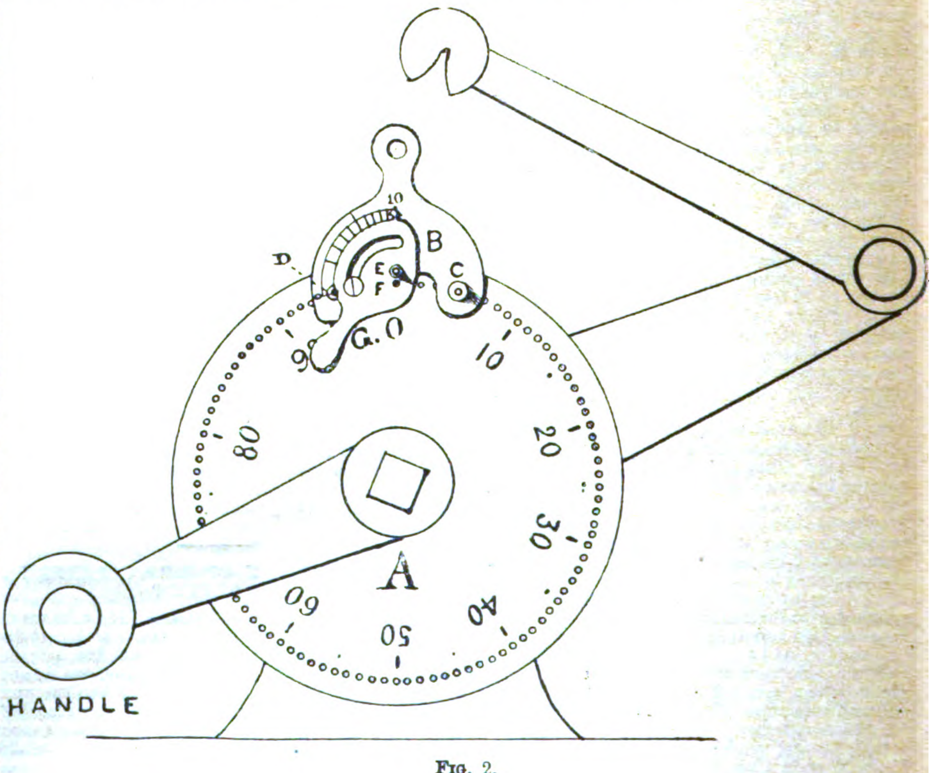

FIG. 2.

G is a quadrant piece, slotted as shown, and capable of being fixed in any position by the screw which passes through it. This quadrant piece rotates on F, which is a small pin attached to the piece B, but not projecting beyond the front of G. It falls exactly over the middle hole between C and D. E is a pin projecting outwards from the face of the attachment, and this pin engages in the notch of the lever L when the latter is let down on it.

The distance between E and F is exactly one division of the row of dots, so that when the pointer on G stands at 10 it is practically over one hole; but when the pointer stands at 0 on the scale, it is over the one before. At intermediate points on the scale it corresponds to tenths of a division, and as it moves eccentrically round F, it practically divides the space between two adjacent holes into ten equal parts.

The scale, which is made without difficulty, is so divided that it corresponds to equal steps of E, as measured on the line of holes. These steps correspond to $\frac{1}{1000}$th of the circle of holes on A, and as the worm-wheel of the lathe has 180 divisions, each step, as measured on the scale of the quadrant piece, corresponds to $\frac{1}{18000}$th of the circumference of a wheel fixed in the usual way for cutting between the centres of the lathe. In cutting a wheel of 6in. diameter, the greatest error which could occur in the setting would not amount to the $\frac{1}{10000}$th of an inch—a quantity probably less than the unadvoidable errors caused by wear of tools, temperature, and other causes.

The management of this apparatus requires the undivided attention of the operator, and a table for each wheel to be cut has to be calculated. For instance, in cutting a wheel of 37 teeth, the first cut will, of course, be at zero, the second will be at 4·864—a number obtained by dividing 180—the teeth in the worm-wheel by 37, the teeth in the wheel to be cut.

The whole number, 4, means four turns of the tangent-screw handle. The next two figures 86, means that the pin, C, is to be set in hole No. 86 on A; and the last figure, 4, is to be set on the small quadrant scale. But in dividing 180 by 37 there was a remainder of 32. This has to be distributed as equally as possible over the 37 teeth—i.e., ·001 is added to each number of the table except five, which five are to be separated as equally as possible.

If still greater accuracy is required, make the piece G large enough to admit of 20 divisions instead of 10. I have cut many prime-number wheels by this method, and they run as smoothly as those with more tractable divisions.

I may mention that, with this arrangement for subdividing the disc on the end of the tangent screw, the whole lathe-head is converted into a micrometer of great accuracy, and with the addition of a screw-piece attached to the lathe-nose, and of, say, 20 threads to the inch, working in a nut properly restrained from going round, a quantity so small as a half-millionth of an inch could be theoretically measured. For such ultra-refinement the piece L must be supplanted by a detent moving radially to A.

Richard Inwards.

20, Bartholomew-villas, N.W.

AN X-RAY CURIOSITY.

[43269.]—IN reference to letter 43238, I would suggest that the greater transparency is only apparent, and that the real cause is fluorescence of the glass, which is probably coloured with uranium, some of the compounds of which are capable of considerable fluorescence under the influence of the X-rays, notably the oxy-fluoride of uranium and ammonium. William G. Collins.

ORNAMENTAL TURNING.

[43270.]—IN answer to "Spherical Rest" (43232) I am extremely glad of the opinion therein expressed. With regard to the procuring of the necessary material, either in ivory or black wood, I am sorry to have to admit the difficulty in both cases, when so large a diameter is required. If our correspondent could favour me with a call, I will do my best to put him in the way of getting the best to be had. Also, shall be pleased to show him the best way of sharpening the step tools, with the aid of small strips of brass, charged with a cutting powder. I think the step tool will be found, when correctly sharpened, a great saving of time. I can probably suggest to "Spherical Slide-Rest" how the expense may be modified by putting together certain parts, which, if well done, will not interfere with the perfection of the work when finished.

J. H. Evans.

DOUBLE-ENGINE RUNNING ON RAILWAYS.

[43271.]—THERE is much to be said in connection with what "Large Boiler" (p. 540) notes, with reference to two engines drawing one train; but he surely does not mean to say that it is a common practice to put two engines on for the through journey. Surely it would be better work to make two trains, for, however skilful the drivers, the two locomotives can scarcely do their full duty always. I see it is mentioned that the water-tubes in the fireboxes of Mr. Drummond's latest locomotives have enabled those engines to do rather remarkable work, and it would seem that every possible inch of heating surface should be utilised. It is not so much a question of the size of boiler, it seems, as the ability of the boiler to supply the required quantity of steam. L. T.

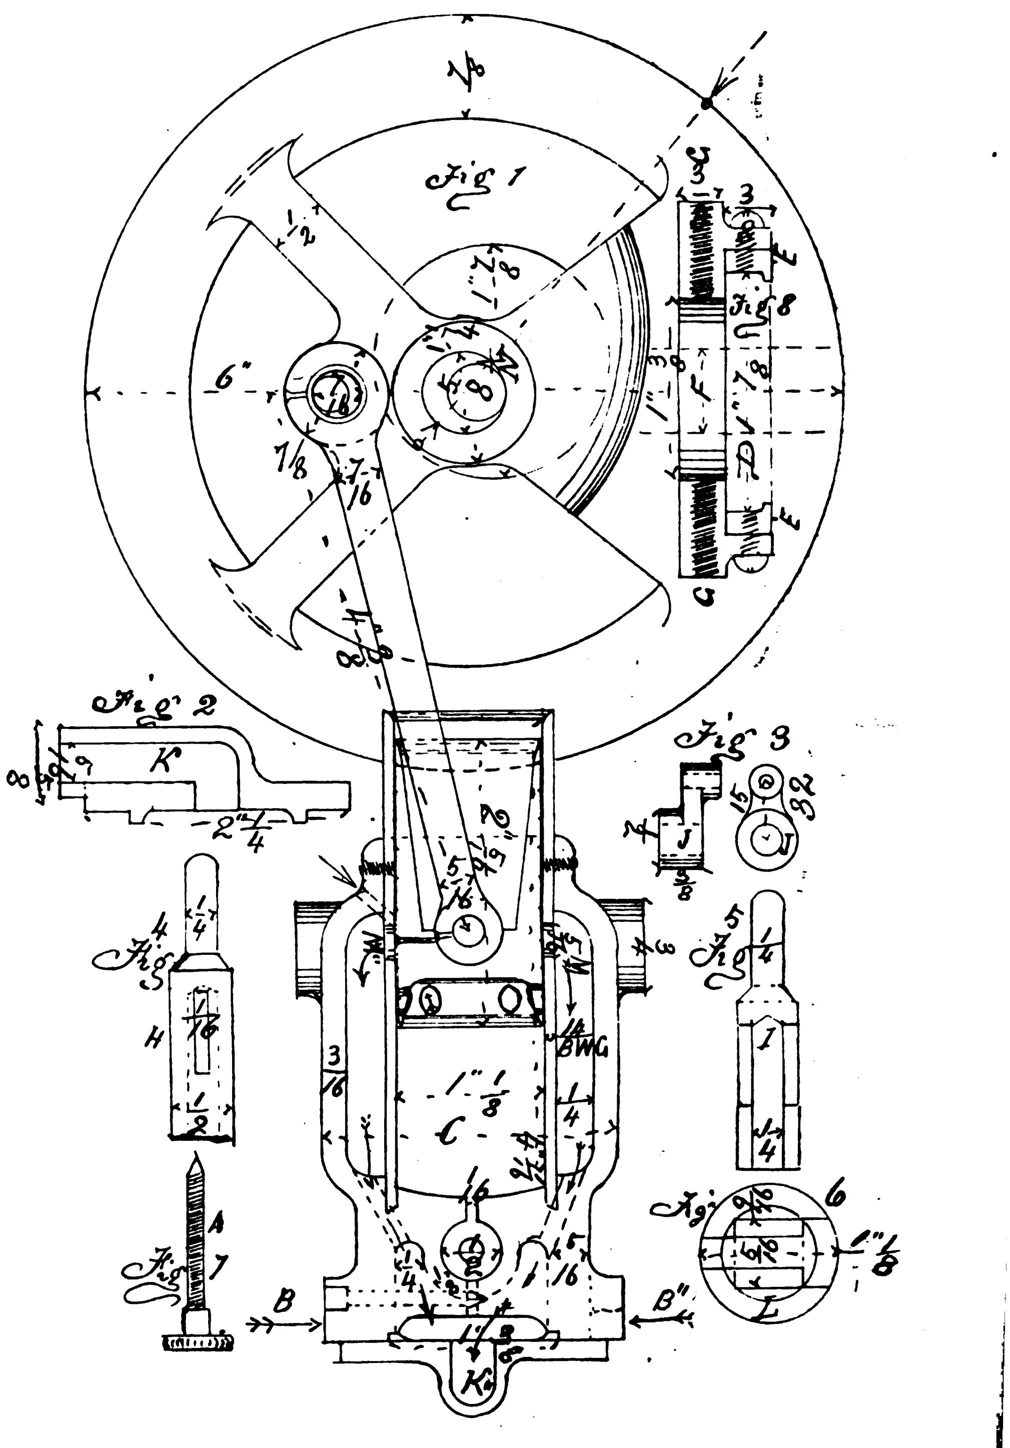
STEAM-ENGINES.

[43272.]—I WOULD like to warn amateur engineering readers of "Ours" against making small *steam*-engines for the purpose of driving a lathe, &c., whether on the lines laid down by "Jack of All Trades" or anyone else. Make *gas* or *oil* engines if you want a bit of power, but *not* steam. Now for the reason why: Some years ago I came into possession of my first lathe, and could not rest till I had made an engine to drive it. Thinking I might wish to add another lathe or an emery-grinder to my stock, I built an engine (steam) of sufficient size to drive all I might require. I then bought a boiler, and my troubles began. I burned coal, and the neighbours complained about the smoke, and I had to use coke. Then came the worst rub of all. Little boilers want attention, and just as you are doing a nice bit of turning you discover that the fire is low, or the pressure is running down, or, worst of all, the water is only just visible in the glass. After altering that, you go on turning, and presently your speed begins to get less and less. Then you remember that you forgot to put any tallow in the cylinder, and you have to do that. In short, you cannot be in two places at once. I have said nothing about pump or injector failures, boiler cleaning, or space occupied, but they must be taken note of. Then, again, it does not pay to wait, say, half an hour while you get up steam, just to do, perhaps, an hour's turning. The above letter is not written to discourage model steam-engine makers, but only to show that steam-engines are not of much use unless you can give the whole, or nearly whole, of your time and attention to them.

E. W. Fraser.

HOW TO BUILD A LIGHT ENGINE FOR VARIOUS PURPOSES.—V.

[43273.]—I HAVE shown you how to utilise the first cylinder for a bracket or wall-engine. Now that is not bound to be positively fastened to and bolted to or through the wall, but could be mounted upon a floor-board, the which I will show further on. This sketch will show you how to construct an engine single-acting, and as I am restricted to space in one sense, and to make it easy to work out details, I make all to the same scale, and give dimensions, and if any of you think of augmenting your power—i.e., substituting an inch and a quarter or larger cylinder, make the jacket mountings larger. All other things will be the same, excepting, of course, the base to which the cylinder stands upon. Fig. 1 is an elevated section of of engine; Fig. 2 is the bonnet for the bottom of the cylinder, and is to be put in that position, as the exhaust will be led through holes at bottom of steam-jacket. See the arrows for path of same. Fig. 3 are two views of bell-crank for working the valve made fast upon the valve spindle, as a matter of course. Fig. 4 is one view of valve, which is rotary. I confine myself to that, as it is the oldest known, and we have ocular demonstrations of its utility in engines of the present day, and it cannot be beaten for effect and simplicity. Fig. 5 is the transverse view; the hole up the centre is the steam-way, and may be carried up to the end of the port, as shown, which will make the said ports much easier to get out. Carry this port right across in every instance. In this instance you will see that it is used to drain the cylinder, from the screw valve at B, where the same discharges itself into the exhaust chamber and out at the bonnet K. Fig. 6 is a section through the trunk-piston pin and joint of the connecting rod. Fig. 7 is the screw for valve for draining the cylinders, and Fig. 8 upon the face of flywheel rim—i.e., not the usual place for it, but when the paper is upon the board and an open space presents itself. I cannot help crowding some more information in the same space as it is only a question of very little trouble on one side while the things are under my eye, and on the other, no more space but a little more ink upon the other side.



This is a somewhat queer sketch, as there is no visible support for the mechanism—like Mohammed's coffin; but it saves confusion, and nuts and bolts I have dispensed with, as there is no need to put them upon paper, and if holes are given for the fixing, there can be no mistake, and it leaves the ground clear. And I suppose I am getting lazy, for I do not see getting things out on a scale of one inch to the foot, and after the trouble they are not readable. However, in the next view of the same, I will make amends as regards the support, as you will have two entablatures for the one engine—i.e., the edge with engine mounted and a plan; so you see it is only a question of time. Jack of all Trades.

MOTOR TRICYCLES.

[43274.]—"MONTY'S" method (letter 43256) of using two motors on a tricycle is ingenious; but I fail to see object of intermediate pinion on back engine, nor that this arrangement balances at all. The pistons both go up and down synchronously. While one is firing, the other is taking a charge and offering comparatively no resistance; on the next up-stroke one is exhausting, and the other compressing—both power-absorbing operations, and I am sure the result would be greater vibration than with single motor. I have a twin-engine tricycle, in which the engines are placed side by side—one in the usual place, the other on the other side of the large gear-wheel. The pistons travel together, but fire alternately. When they work properly, the machine is very powerful; but the difficulties of ignition are great. To save correspondence, I may say I do not intend to carry two coils or two batteries; but if some reader can suggest a method of firing these engines regularly without complication, I shall be glad to hear from him. I have tried

tube-ignition; brush commutator for secondary, with electric ignition; two plugs in parallel, two plugs in series. Now I have a cam current-shifter on the lay shaft for secondary, but cannot insulate sufficiently for a wet day. The machine devours petrol by the bucketful, and runs batteries down in a day. It makes more noise than a Maxim gun, and is perilously prone to tip up.

To revert to "Monty's" letter. What has "even divisible number of teeth" to do with it? The engine-pinion must go tooth for tooth with the axle gear-wheel, and if both engines have same size pinions they *must* synchronise. If I were to adopt "Monty's" position for my engines, I should run both engines in the same direction, but one piston up and one down; this gives a bad torque, but does balance a little, and is, in my opinion, worth trying. It is done in the Decauville car. Will "Monty" say what he thinks about this device? **H. Scott Russell.**

MOTOR-CARS.

[43275.]—I HAVE heard it objected to a jockey-pulley that, as usually applied, it causes an injurious reverse bend in the belt. If this be so, might it not answer better to apply the jockey at the place where the driven pulley is first touched by the belt, which would thus be pinched between the two pulleys. In this position there would be no effort of the belt to straighten itself against the pressure of the jockey, as in the ordinary method, and, therefore, the jockey might be applied with greater power.

As to the guide-pulleys in "our" motor-car (if I may call it so), which have been so much objected to, could not the one (or, rather, the two) to the left of H be dispensed with—with very little loss of brake surface—by connecting the brake-rods directly with the short cranks on centre, U, these being rotated clockwise into the same line as the long handle?

I should certainly prefer a bell-crank in lieu of the other pulley (above Z), especially as the turn is a sharp one; and the joints in this linkage need not be elaborate ones *if* the spring that takes off the brake be next it, not next the pedal. Indeed, I believe simple hooks and eyes would answer perfectly, for I have had two tricycles in which the five joints between the hand-lever and the hand-brake were of this type, and they were quite satisfactory, for they were cheap, gave great freedom of movement, and required no oil.

All rods were in tension, and therefore light, one having a turn-buckle for adjustment, which, when properly done, rendered the linkage quite free from rattle. Of course, the pedal must be pulled up against a stop.

Seeing that the connecting-rod is always in compression, and that, therefore, the outer half of its big-end bearing is merely a cup to keep things in place, would it answer (and get rid of the need for adjustment) to put on the studs, in place of nuts, short, stiff spiral springs, secured by cotters? It seems to me extraordinary that, so far as I know, no maker fits efficient gear-cases to the driving-chains of his motor-car. How can an elaborate and costly piece of mechanism like the modern pitch-chain be expected to work and wear well when exposed to continual showers of mud or dust?

Most small cars depend for varying their pace upon altering the ignition. Is not this a mistake? For if a given speed of the engine should be associated with a definite timing of the spark, it would seem better that this timing should be regulated by a governor, not by hand, and that the pace should be altered by adjusting the throttle-valve. This valve ought, it seems to me, to be coupled with the air-valve, so that both should move together, yet so that the air-valve could also be adjusted by hand when necessary. **Faber.**

[43276.]—THE majority of those criticising my design of motor and car have missed the main points—simplicity and cheapness; and I would ask that future critics would bear these in mind. There are many details I could, and should like to, alter and improve, but for the cost they would involve.

I am pleased to see Mr. J. W. Riding (43230, p. 513) has constructed a car with such complete control as his letter describes.

Mr. A. Jacks (43231, p. 513) complains of the short wheel-base; but I fail to see the disadvantages in this for a car which is not intended for racing. I have allowed ample room for anyone to mount or dismount, and consider the short wheel-base to help considerably in steering the car in traffic. Its width is ample to prevent any tendency to overturning. As to the frame, I must repeat what I said in the first article. It may be made of any material the builder may prefer. The same sizes (width and length) will, of course, be required; and if readers are capable of working angle, channel, or H-bars, or steel tubes, very little else in the way of dimensions will be required by them. I will give the sizes of angle or channel-bars and tubing suitable in the chapter dealing with the frame. When I stated that I did not know of a car on the market with belt driving, in which the action of putting on the brake also disengaged the engine, I was not thinking of cars fitted with friction clutches, as I regard this type as being midway between belt and gear-driven—not purely belt-driven.

The question of using a greater-powered motor is fully answered by consideration of the cost. The horizontal valves to which "Dragoon" (43254, p. 539) objects work quite well. I have used them on several motors, and have no fault to find with them. Moreover, disposing them in this way simplifies the valve-gear somewhat. Let "Dragoon" make a full-sized horizontal section of the cylinder and the valve-box on separate pieces of tracing-paper. The valve-box to be drawn as it would be if the valves were vertical. On placing these one over the other he will find that two of the studs will come far in the rear of the cylinder end if the same compression space is to be maintained. That unfortunate bell-crank lever was put in for an object. I stated in the first article I would show later how a governor could be fitted. The governing will be effected by a "hit or miss" arrangement between the push-rod and bell-crank lever. Hence its *raison d'être*. I am fully aware that it could have been dispensed with, as perhaps will be evident on referring to my drawings in the articles on "Motor Cycles." The next paragraph of "Dragoon's" letter seems somewhat vague; but if I read it rightly I take it he would have the combustion chamber connected by pipes to the water-jacket. I would point out that I am describing a petrol and not a hydraulic motor. If a water-joint is a nuisance it is evidence of bad or careless workmanship. Properly made, they will stand for a very long period, and should be no more a "weak point" than any other part of the motor. As the cylinder is to be of cast iron and the crank chamber of aluminium, I am afraid technical difficulties would stand in the way of casting them in one piece. A cast-iron crank-chamber is, of course, possible, but would be inconveniently heavy. The difficulties in machining would alone be sufficient to condemn this one-piece idea from an amateur's point of view. In a well-equipped engineering works such an objection would not count.

Built-up cranks are not so good as a solid forging, and little, if anything, would be saved in the cost, wherefore I do not describe one. Re putting valve gear-wheel inside crank-chamber: I have adopted the most simple and easy construction. I most heartily agree with the last paragraph of "Dragoon's" letter.

"R. W. B." (43255) also falls foul of the bell-crank lever. This I refer to above, so need not explain again. I would add, however, that by its use a more easy movement of the gear is obtained, there being no side strain and friction on the push-rod. I notice that some of the best French makers are abandoning the use of the straight push-rod in favour of a lever and roller, notably in the "Sphinx" cycle motor.

The Daimler Motor Co. do not fit perch-bars to their front axles; but, if desired, they can be fitted to ours, and I will incorporate them as an addition. In this connection, I would remark that if I were to describe every addition suggested by various critics the cost of the car would be prohibitive. I agree in the matter of not using steel wire cord for band-brake. It is very unreliable and wears out quickly. I shall use a steel band leather-lined. Has "R. W. B." ever seen a Daimler motor of recent construction? If so, why does he refer to the arrangement I give for valve springs as "slipshod"? Has he also considered that for equal efficiency the less the number of parts the better? The Daimler Co. always hook the ends of valve-springs through the rods, and very neat it looks, besides working well. The same firm also use non-adjustable small ends to their connecting rods, and for a considerable time did not even bush them. They case-hardened the small end of rod, which is a mild steel stamping. The plain bushed small end works well, and, when needed, it is a small matter to put in a new bush.

Has "Monty" ever tried to synchronise two motors arranged as shown in his design for motor tricycle? If not, he will have enough experimenting to last him a twelvemonth or more.

The Writer of the Articles.

WEATHER.

[43277.]—IN a letter which appeared on p. 496, I mentioned that "many of those who work in London live, say, five miles north," &c., and they are convinced of the futility of predicting weather for even so small a place as England. For "England," I think I might now write London. On Sunday morning last, quite a heavy fall of snow was seen at Wimbledon, Chiswick, Camberwell, Clapham, Dalwich, Clapton, and Regent-street; but there was no sign of it at Forest-gate, Upton, or East Ham, places as far to the east of St. Paul's as Chiswick is to the west. At Bardett-road (about three miles east of St. Paul's) there was just a little snow, which melted almost directly; but further east there does not seem to have been more than a suspicion of a little sleet, which is understood to be partly-frozen rain. I suppose that the clouds deposited their snow on the west side of London, and, passing over the great city, became so warmed that the moisture could not freeze into snow. **S. R.**

THE TWENTIETH CENTURY—ERRATUM.

[43278.]—I REGRET that a confusing error has got into print in the last paragraph of my letter (43258) on the Twentieth Century. Anglo-Russian documents are dated thus:—

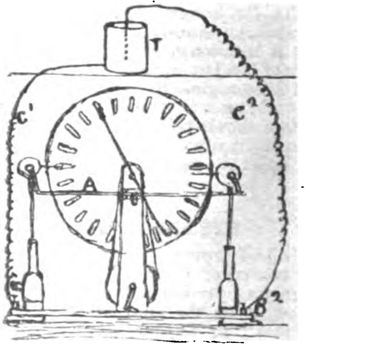
$$\text{Thursday, 1900, March } \frac{2 \text{ O.S.}}{15 \text{ N.S.}}$$

The day of the week is the same, and so, practically, is the course of the seasons in Moscow and London. But in 1752 our English Calendar was treated like a behind-time clock. It was "reformed" by being put on 11 days, and its clock-work was regulated so as to make it go faster in future, and keep up to date. In Russia the Julian Calendar has never been brought up to date, nor has its clockwork been revised, and in a few weeks now it will have drifted back a further two days. It therefore follows that in Russia, the seasons of the year, and the festival days based on those seasons, will not be indicated by the calendar until they are 13 days past. **James Edmunds.**

26, Manchester-square, W.

PECULIAR EFFECTS UPON SPARK DISCHARGES.

[43279.]—THE following account of a phenomenon I have observed may be of interest to some of your readers. The accompanying sketch illustrates the arrangement of apparatus:—



C^1 is a conductor connecting the tin T to the terminal B^1 of a Wimshurst machine. C^2 is a conductor from the terminal B^2, which hangs, reaching about 1¼in. from the bottom, and thoroughly insulated from the tin can. A is a double spark-gap arm. When the machine is working the sparks passing in the tin can (which produces a sharp hollow sound) are almost deadened by the sound produced by the sparks passing between the double spark-gap. But on placing the hand upon any part of the arm A, the discharges passing between the two spark-gaps are hardly audible. On the contrary, those inside the tin can are very plainly heard, even in an adjoining room with doors shut. I have performed this experiment a number of times, always obtaining the same results. I should very much like to know the cause of this phenomenon. Perhaps one of your readers may be able to explain this. **A. Stammwitz.**

THERE were 951 ships of 267,642 gross tons built in the United States last year. Of this number 421 were steamships of 160,132 tons gross.

CLEANING bridges by sand-blast has been tried on five structures on the Boston and Maine Railroad. The work is entirely satisfactory, being more thorough than hand cleaning. A pressure of 15lb. per square inch is employed, and the sand has to be perfectly dry.

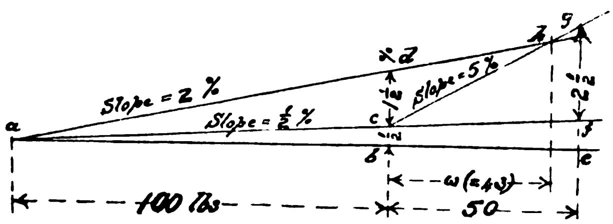
A SCHEME has been prepared for the construction of a system of underground electric railways in Berlin. The project, which has already been approved by the mayor and the traffic committee, will shortly be submitted to the municipal authorities, who will be asked to approve the carrying out of the works. It is proposed to construct two circle railways and two transverse lines from north to south and east and west respectively. The scheme provides for the building of the railways by private enterprise at the expense of the town; but whether they would be leased to a company or worked by the city authorities is a question for the future to determine. It is belived that the railways could be completed and opened to traffic in two years from the time of commencement, as was the case with the underground electric railway in Buda-Pesth.

REPLIES TO QUERIES.

**** *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[96919.]—**Flying Lady.**—I saw this performance at Blackpool, and distinctly heard the squeaking of the machinery behind the black curtain at the back. At the time I believed that she was fastened behind to the end of a long lever. The system of bright lights and black background was arranged to prevent anything being seen. A hoop was certainly drawn in various ways around her; but they should certainly oil their machinery to make the trick complete. H. WADSWORTH.

[97069.]—**Formula (U.Q.)**—Perhaps a graphical solution will be of interest. Draw a horizontal line and mark off a length $a\,b$ to represent your 100lb. of ½ per cent. solution to any convenient scale. With the same or any other scale mark a perpendicular height $b\,c$ to represent ½ per cent., and $b\,d$ to represent 2 per cent. From a draw lines through c and d, as shown. Through c draw $c\,g$ at a slope corresponding to 5 per cent. To do this, measure



100 horizontally and 5 vertically from $a\,f$, or, as has been done in the figure, use other figures in the same proportion, such as $b\,e$ horizontally = 50, and $f\,g$ vertically = 2½. The intersection of $c\,g$ with $a\,d$ produced at h gives a length w (= nearly 43lb.), which is the weight of 5 per cent. solution which must be added to obtain a 2 per cent. solution. Mathematically: By the terms of your question it is evident that—

$$\left[(100 + w) \times \frac{0.5}{100}\right] + \left[w \times \frac{5}{100}\right] = (100 + w) \times \frac{2}{100}$$

Hence—

$$w \times \frac{5}{100} = \left[(100 + w) \times \frac{2}{100}\right] - \left[(100 + w) \times \frac{0{\cdot}5}{105}\right]$$

$$= (190 + w) \times \left(\frac{2}{100} - \frac{0.5}{100}\right)$$

$$\frac{\frac{5}{100}}{\frac{2}{100} - \frac{0{\cdot}5}{100}} = \frac{100 + w}{w} = \frac{100}{w} + 1$$

Hence—

$$\frac{5}{2 - 0.5} - 1 = \frac{100}{w}$$

$$w = \frac{100}{2{\cdot}33} = 42{\cdot}8\text{, or, say, 43lb.}$$

GLATTON.

[97180.]—**Marine Navigation.**—As a marine engineer of ten years' experience, I can fully substantiate the reply of "J. H. H." in "E.M." for Jan. 19. "G. S. N." appears to have a very hazy idea of modern marine-engine practice. He probably has not heard of the "Davey" motor, which is a steam-engine worked with barely one pound of steam. This is a surface-condensing engine. A partial vacuum is first obtained by means of a small pump worked by hand. Steam from the boiler (at, say, 1lb. pressure) is then admitted to cylinder, and after a few revolutions of engine, the air-pump worked by engine produces a vacuum of about 27in., which practically works the engine. When triple-expansion engines of a large steamer are working dead slow, there is really no more steam in low-pressure steam-chest than would be obtainable from the exhaust of all the auxiliary engines; but having once established a good vacuum in condenser, the main stop-valve could be almost or entirely closed if the exhaust from auxiliaries were turned into low-pressure receiver. "G. S. N." is puzzled to know what the boilers do with the evaporated water. Perhaps he is not aware that the boiler feed is not supplemented as in bygone days with water direct from the sea, but with condensed steam from evaporated sea-water, nearly all up-to-date high-pressure jobs being fitted with what are known as "evaporators." CHARLTON.

[97180.]—**Marine Navigation.**—I regret I am unable to refer "G. S. N." to any work on marine engineering which treats of the subject in question. There are but one or two such books in existence, and for a very good reason—viz., marine engineering practice advances with such rapid strides that any work dealing with it necessarily becomes practically obsolete in a very few years. But the reasons which lead to the utilisation of exhaust steam from auxiliary engines in the main engines are very apparent when the subject is looked into. Take, for instance, a liner with boilers working at, say, 150lb. above atmosphere. The auxiliary engines are mostly "simple" engines—that is to say, not compound. The cut-off in these engine cylinders will be at about ·6 or ·7 of their stroke, and the exhaust steam therefore leaves the cylinders at considerable pressure, even after making allowance for loss from various causes. To realise this, one has only to listen to a locomotive with a heavy load behind it. Now to discharge this high-pressure exhaust steam direct into the condenser would be to lose all the work still left in the steam. Therefore it (or some of it) is passed into the receivers of the i.p. or l.p. cylinders of the main engines, and some of its work extracted by the main pistons. Compound auxiliary engines are not possible for many purposes, chiefly on account of the variations in the load under which they are required to run. Otherwise, their use would obviate this waste of useful steam. The aim of using this exhaust steam in the main engines is then to avoid waste so far as is possible, and as every year sees more auxiliary engines added to our first-class ships, so the difficulty increases. As I pointed out in a former reply, this steam may be passed through evaporators, and so used to produce distilled water to supply loss of water from the boilers by reason of leaky joints, glands, safety-valves, whistle, &c., and which in the Navy is very great. No sea-water is allowed to be used in Naval boilers under any circumstances at the present time. A large quantity of distilled water is therefore required, and part of it is obtained in the above manner. Referring to the original query about driving the ship four knots with exhaust steam, it should be remembered that a very small pressure per square inch on the l.p. piston will turn the engines after a vacuum is once established, and a very small number of revolutions of the engines are necessary to maintain a speed of four knots. J. H. H.

[97196.]—**Science and Art Department Certificates.**—On p. 475 I mentioned that in replies on p. 409 I gave the price of the "Directory" as 6d., while "Clara" gave it as 1s. 6d. Being in the neighbourhood of the publishers the other day, I called in and found that the price is 6d. It appears that by an error the price on some copies was printed 1s. 11d., and that being altered by pen to 6d., appeared occasionally as 1s. 6d. If anyone has paid 1s. 6d., there is a shilling to come back. I have some recollection that, by one of the rules and regulations of the Department, or by an order of the House of Commons, the "Directory" of the Science and Art Department should never be more than 6d., no matter how many sheets it contains. It is probably in reckoning up the price per sheet that the mistake was made. M. T.

[97216.]—**Grammaphone (U.Q.)**—There are no larger records to be bought, as far as I know, than the 7in. ones. Of course, you could make them any size in reason if the dimensions of the machine were altered to suit.

R. A. R. BENNETT.

[97221.]—**Telectroscope.**—If "F. H. E." will refer to what I said on p. 518 (he strangely omits to give the reference), he will find that I was talking about being able to see round a corner by means of a wire—the telectroscope notion. Any schoolboy knows all about seeing by means of reflection: he has seen through a book or a brick by that means long ago. The query I noticed appeared on p. 388. I cannot deal with all the "red herrings" drawn across that trail. The real question is "seeing by wire"—not by reflection from mirrors. T. P.

[97231.]—**Moving Hearth-Rug (U.Q.)**—This reads like spiritualism, and has almost the effect desired by the Fat Boy in "Pickwick"; but I am inclined to attribute the phenomenon to more prosaic sources. We have an Axminster carpet, with an Axminster rug to match, which does the same thing; in fact, it insists on advancing in so forcible a manner that it actually opens the door before which it is placed if this is not very tightly shut. It is, I think, simply due to the pile of the carpet underneath, which moves it gradually forwards when the strands of the carpet are pushed forwards by people treading upon the carpet behind the rug. But why should the rug go forwards during the night? I do not think ours has ever done this. I suppose the querist means that no one had entered the room between the hours mentioned?

R. A. R. BENNETT.

[97286.]—**Specula.**—If this querist ("Astor," p. 432) will refer to the back volumes, he will find all the information he can require; but if he cannot find it in them, it is certain he will not find it anywhere. Surely Mr. Wassell's articles are sufficient, to say nothing of the many which preceded them, and of others which have followed. It is not even easy to understand what is "Astor's" difficulty. He has "tried ineffectually," he says; perhaps if he tries again, and yet again, he will succeed. One thing is certain—that he can obtain instructions from practical men, who will show him how to do the work. As no reference is given to the machine mentioned, it is scarcely likely that readers will wade through back volumes to find out.

GRINDER.

[97292.]—**Cycle Plating.**—If sufficient information cannot be found in back numbers (which is doubtful) the querist might consult Bonney's "Electroplater's Handbook," published by Whittaker and Co. The "cycle work" has nothing to do with the question—any plant capable of coppering and nickelling will do, according to the size of the parts to be plated. There is nothing special in "cycle work." I presume the querist knows that "coppering and plating" can be done with economy only on the large scale—a scale, at least, large enough to use a dynamo and the energy given out by, say, a small gas-engine. Batteries cannot compete. ESSAR.

[97294.]—**Acetylene Gas.**—If "Robbie Burns" cannot succeed in working with acetylene gas after studying the numerous schemes given in previous numbers, I am afraid it is useless to endeavour to help him. What sort of a 4in. reflector is it, and is the light properly placed with regard to the reflector? Possibly the condenser is wrong; but no particulars are given, and it is not worth while guessing what querists mean. Surely, when asking a question, it is only courtesy to give the data in the fullest possible way. I have no doubt that replies would be returned to every query that appears if only the querists would state definitely what it is they want. SABRAS.

[97306.]—**Thorite as an Explosive.**—Cannot find any mention of thorite being an explosive. Possibly the "thorite" of the query is some fancy name given to a trade article. The paragraph quoted seems to me to be a hoax perpetrated on the news-agencies, and so has been circulated during a period of "excitement." The querist should inquire of the editor of the paper in which he found the statement. N. F. J.

[97308.]—**Salicylate of Soda and Uric Acid.**—With all due deference to "D. W. A.," I must adhere to my opinion *re* uric acid, which is founded on facts that "D. W. A." may possibly, or may not possibly, know. Salicylate of soda does not dissolve out uric acid, and the clue to "D. W. A.'s" headaches is furnished by implications from his statement that he has chronic rheumatism. Uric acid is not increased as a result of rheumatism alone, either in the blood or in the urine, and "D. W. A." must beware of the "Post hoc, ergo propter hoc" fallacy. Sal. of soda is a well-known cure for rheumatoid headaches. Possibly it may interest "D. W. A." to know (1) that uric acid in itself is not the cause of the symptoms referred commonly to it, but certain tissue-poisons formed under like conditions, which may cause the evil when there is no increase of uric acid; (2) that alkalies, to which he ascribes his relapses, are given to *cure* the uric acid diathesis; (3) that the condemnation of salt (sodium chloride), which one of his authorities so fiercely reiterated, is exactly contrary to experience, so that sailors, who eat a lot of salt, hardly ever suffer from gout or stone, while stone and gravel are exceedingly common among the natives of India, who live almost wholly on rice.

Galway. M. B.

[97316.]—**Zinc Printing - Blocks.**—The "simplest" process is to draw the lines on the zinc plates with a "resist" ink, and then eat away the surrounding metal to so much that the lines would remain as a sufficient printing surface. Obviously, if there are many lines to be drawn, it would be more economical to make a drawing, photograph that, and transfer to the zinc. There are plenty of manuals on the subject nowadays, and, I suppose, all the processes have been described in these pages. If patented, a full account can be found in the specifications. T. L.

[97345.]—**Wax Phonograph Records.**—To clean phonograph cylinders, rub them with a fine cloth wet with spirits of turpentine; after the grinding noise ceases, do the same with a cloth wet with wood alcohol; and after this operation polish

with a dry cloth. Of course, in all these operations the cylinder must be rotated at a good speed in the phonograph itself or in a lathe; the last operation, if a very high polish is required, necessitates the highest speed. With this method three records can be cleaned in the time it takes to shave one, and a surface obtained far superior to any obtained by the shaving process alone. It is, of course, vital to have high speed, as a slow one will make record untrue.

WM. F. RIGBY.

[97361.]—**Clock-Weight.**—Thanks again to Mr. F. M. Mann. I said nothing about the actual (only the comparative) weight. As a matter of fact, it is nearer 15lb. than 5lb. I will find out the arc of swing of my pendulum. I should say it was 6° or 8°. C. D.

[97382.]—**Rats.**—Every winter I have a renewed warfare with the rats that infest my farm buildings and house. I cannot entirely get rid of them once for all, as they have several old banks to retreat to, where they can restore their numbers in the summer. The most effective cure is poison. I always use Barton's, but you cannot safely use poison when there is food about, for instance. A resort must then be had to traps or ferrets. The easiest, as well as the most effective, way of trapping these artful creatures is as follows: Procure some good rat "gins," place these in shallow boxes, and cover entirely with bran to the depth of, say, ½in. over the gin; upon the bran just over the table of the gin place a few sunflower seeds. In my experience this is the most enticing bait for rats that can be used. It never fails to draw them over and over again. I saw this bait recommended in the *Bazaar and Mart* several years ago, and have often used it since. Do not use the naked hand in setting the gin, and pour the bran out of a bag. The scent of the hand deters the rats from trying the snare. The same remark applies also to the bait. Do not handle it. STELLA.

[97394.]—**New Moon.**—As this query is put I cannot see what "astronomical contributors" specially have to do with it. A series of almanacs will show when in recent years there was a February without a new moon or without a full moon, or without a first quarter, &c. A question as to why there is no new moon this year in February would be astronomical, but the short answer is: There are only 28 days in February, and the new moon just escapes—skipping from Jan. 31 to March 1. As to when the event will recur next, that would involve a rather long calculation; but probably it is already worked out at the *Nautical Almanac* office, and possibly one of the officials there may see this note and reply. A. F.

[97398.]—**Climate of China.**—Much obliged to correspondents who have kindly noticed my query; but they appear not to have observed the real point which is "Pekin, China, is frozen up for six months of the year." I don't think so—not quite so long. That's where the query comes in. F. F.

[97403.]—**Patent Accumulators of Woven Glass.**—I had occasion to test one of these—a 5 amp. 40 amp. hours accumulator. It had been in use some time on a motor-car for ignition, and wanted recharging at 5 amp. After doing this in seven hours I discharged it, going slowly up to 10 amps. I then discharged it at 10 amps., and discharged it at a high rate, drawing for several minutes as much as 40 amps. I quite expected to have completely destroyed the plates, but found on taking it to pieces that the plates were not buckled, and that the lead oxide had not dropped out. As a matter of fact, it is not easily done, because all the plates are packed tightly together, being separated by a sheet of spun glass. The woven grid seems to hold the active mass very firmly, and makes the plates look like solid lead. The space between the spun glass threads seems sufficient to allow the acid to circulate. Since the accumulator works well after recharging it at the given rate, I have no hesitation to recommend them to "Windmiller." The ebonite lining of the wooden box seems to me a good plan, as it prevents the rolling of the wood, and wood prevents the ebonite getting broken. I prefer them to other accumulators, as most of those I ever saw seem to go wrong very soon, and usually are losing the charge after having been at rest for some length of time. W. H.

[97406.] — **Ulcer of Stomach.** — "Tempus Fugit" is acting in a very reprehensible manner if he is going to tinker up such a serious and acute case of ulcer in the stomach himself. If he can afford it, call in a doctor; if not, send the patient to a hospital. But he is taking on himself a serious responsibility to let such an acute case drift without help.

Galway. M. B.

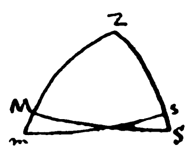
[97416.]—**Leclanche Cells**—Sealed cells are never a success; the more air that gets to the carbon the better. If you want a large current for a very short time, increase the zincs from rods to plates. If, though, for continuous working, keep the zincs small and the carbon surface large. Always amalgamate the zincs once: any crystals adhering are then easily removed, but it is rarely they form on amalgamated zincs. Put nothing at all in the way of paints on the outsides of the zinc cylinders: it is more nuisance than good. Wrapping the carbons in canvas has nothing to do with the polarisation: the canvas is merely to prevent the particles that fall off the carbons touching the zincs, and thus reducing the power of the cell by short circuiting the carbons and zincs.

L. A. I., Electrical Engineer.

[97431.]—**Gas-Engine Valves.**—Your valves did not ought to want grinding in, and your seat, i.e., cone, did not ought to be above $\frac{1}{32}$ less if anything. Drill a small hole up into your valves and tap them, then screw a piece of wire and screw in tight; take a cut off the face of seat or off the valve to reduce cone, and use powdered pumice-stone or silver sand for grinding—no emery.

JACK OF ALL TRADES.

[97434.] — **Spherical Triangle with Side > 90°.**—To find log. sin. 101° 14′ 3″, we should subtract from 180°, and look up in the tables for log. sin. 78° 45′ 57″, which is equal in value. Or, we might subtract 90°, and look for cos. 11° 14′ 3″, which is the same thing. As a general rule, when a trigonometrical function of an angle greater than 90° is required, either subtract from 180° and look for the same function of the angle thus obtained, or look for the co-function of the excess of the angle over 90°. For log. sin. ($\frac{1}{2}$ Σ − M S), we should subtract M S from the true value of $\frac{1}{2}$ Σ—e.g., 99° 44′ 49″ from 101° 14′ 3″ in the example quoted. I do not quite understand how "Fleur-



de-Lys" solves the lunar distance problem. The second of his formulæ requires the angles at M and S (true positions of moon and star) to be known, while his first formula could only find the angle Z; and the angles at *m* and *s* (apparent positions of moon and star). The finding of Z from the triangle Z *m s*, in which the three sides are known, is, of course, part of the problem. We then know, in the triangle Z M S, the angle Z, and the sides Z M, Z S, and could finish by finding M S from the fundamental formula—

$$\cos. MS = \cos. ZM \cos. ZS + \sin. ZM \sin. ZS \cos. Z,$$

but as this, containing a +, is not adapted for logarithmic computation, it is better to use the following:—Find subsidiary angle θ from—

$$\tan. \theta = \tan. ZM \cos. Z.$$

Then—

$$\cos. MS = \cos. ZM \,.\, \cos. (ZS - \theta) \,.\, \sec. \theta.$$

Here it must be noted that if Z > 90°, cos. Z will be negative, and hence also tan. θ. Therefore θ is negative, and we must remember to add its numerical value to Z S in finding Z S − θ.

ARCTURUS.

[97435.]—**Electrical Power.**—Electric-lighting stations are commercial undertakings, and the querist may rest assured that there is no considerable amount of power allowed to run to waste in the one he speaks of. Every unit generated is accounted for, and leakage anywhere on the system is immediately discovered. His misunderstanding has probably arisen from having heard that the machines are "earthed"; but this is done merely for convenience or safety, and no loss of power is occasioned. R. H. PARSONS.

[97435.] — **Electrical Power.** — We should imagine you are wrong in supposing that any portion of the 5,000H.P. is allowed to run to waste. Even if 1,000H.P. were running to waste, it would not be possible for you to recover any portion through tapping the ground.

Dudley. WEBSTER MICHELSON AND CO.

[97439.] — **Gauge Sticking.** — See that the pointer is not in contact with either the dial or the glass. If not, remove the case and examine the motion inside, which has probably become clogged with dirt. If you find it necessary to take the gauge to pieces, test it at all pressures by comparing it with a standard gauge before using it again.

R. H. PARSONS.

[97440.]—**Governing Engine.**—As neither the type of governor nor the manner in which it is fixed is specified, it is rather difficult to advise. The governor is presumably one of the old slow-speed pendulum pattern, and, if so, will never govern satisfactorily with a fluctuating load. A governor should run at three or four times the speed of the engine, so that an increase in the engine's speed is multiplied on the governor. I should advise you to fix a high-speed governor of the "Acme" or "Pickering" type, with an equilibrium throttle-valve if the conditions admit. R. H. PARSONS.

[97436.]—**Stamping Notepaper.**—The ink is applied to the die by means of a stencil-brush, Fig. 1. It should be well rubbed in until every letter appears filled. The superfluous ink is removed by rubbing the face of the die across a paper pad in the manner indicated by Fig. 2. This operation, though apparently simple, requires some practice before satisfactory results are obtained, but if it is done with despatch the surface should be left perfectly clean, whilst the ink remains in the letters.

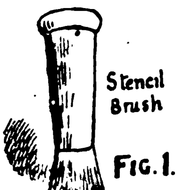


FIG. 1.

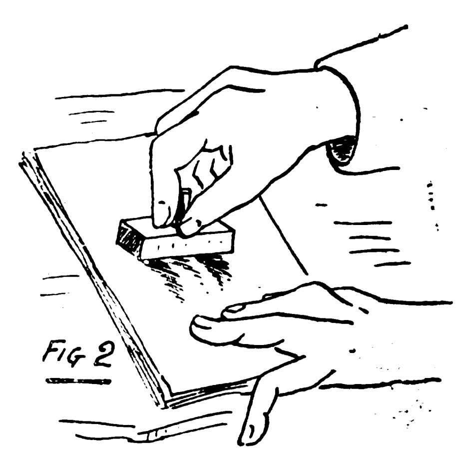

FIG 2

When a hand-press is employed, the reverse is made of cardboard backed up with a composition capable of being squeegeed into the indentations of the die. This reverse should be cut away except where the lettering comes in contact. When the die is not in use, it should be coated over with white beeswax; this will prevent rust, and keep the die ready for use on future occasions.

THEODORE BROWN.

[97441.]—**Enlarged Tonsils.**—If the "growth in the throat" means enlarged tonsils, then the question whether operation is necessary could only be settled by a doctor for some time in charge of the child. If the tonsils are subject to chronic inflammation, which spreads to the throat and soft palate, if they are hardened and enlarged, threatening to fill up the back of the mouth and obstruct swallowing and breathing, then they are better out. The operation, with modern instruments and skill, will not take a minute by the watch, the child merely standing up and opening its mouth. With proper skill there is no danger, though sometimes the hæmorrhage may be hard to stop. Good fresh milk, butter, and eggs, and emulsion of cod-liver oil will help to sustain the strength of the patient.

Galway. M. B.

[97443.]—**Face-Plate.**—Unless your lathe has a tool steel mandrel it will probably bend, or at least get a set on it, in turning such a heavy plate. My experience with excessively heavy face-plates is that they absorb too much power to drive them, and require very much larger mandrels than usually fitted to carry them satisfactorily. I have a 9in. lathe with a 30in. plate, weighing upwards of 3cwt. The tremor set up by the revolving of such a weight is such as to make turning on it impossible.

Bromley, Kent. A. F. SHAKESPEAR.

[97443.]—**Face-Plate.**—It all depends upon what diameter your front bearing is; but, if made properly, it ought not to weigh more than 70lb., or 75lb. at most. Why should you bend your saddle in turning it up any more than turning up one of 12in.? If you use a Scotch tool as shown in the Number for Dec. 15th, 1899, p. 407, you will be able to do the job like the paring of cheese, i.e., if your metal is good. Of course, you must not run your lathe at the highest speed with that chuck on, or you will come to grief. I once saw a 3ft. chuck with an eccentric strap mounted on it. It was mounted upon a 12in. centre-lathe. The gaffer who was doing the job was very fond of finishing his job with emery and a stick. He did not seem capable of finishing a job otherwise, so he slips out the back gear and locks the spindle, and starts for polishing, when snap! and the spindle seized and was fast; off goes the plate and the job on it, right over a fitting bench, where two men were only

half a minute before at work. Had they been there I don't know how things would have ended; but the thing went right over to the other side of the shop, over everything, a distance of 40ft. No one stood in its path as luck would have it.

JACK OF ALL TRADES

[97444.]—**Tank-Sinking.**—During the time the tank is filling, the difference between the water inside and outside will be approximately constant and equal to 4ft. Thus the water will enter with a velocity due to a head of 4ft.—i.e., $\sqrt{2gh}$, or 16ft. per sec. The volume of water which flows in is therefore $16 \times \cdot 6 = 9 \cdot 6$c.ft. per second. The tank will not sink until it contains $20 \times 30 \times 5 = 3{,}000$c.ft. of water, which will evidently require $\frac{3{,}000\text{sec.}}{9 \cdot 6}$ to enter. The answer is therefore 312·5sec., or nearly $5\frac{1}{4}$min.

R. H. PARSONS.

[97446.]—**Deflection of Oak Beam.**—D = deflection, W = force of the blow, l = length of span, b = breadth of beam, d = depth, I = moment of inertia, E = modulus of elasticity. Then the work done in deflecting the beam $= \frac{W}{2} \times D$ = the kinetic energy of the body. Therefore—

$$\tfrac{1}{64} M V^2 = \frac{W}{2} \times D$$

But for a beam fixed at the ends and loaded in the centre, the deflection is given by $\frac{W l^3}{192 E . I}$. Therefore—

$$\tfrac{1}{64} M V^2 = \frac{W l^3}{192 E I} \times \frac{W}{2}$$

$$140\text{ft.-lb.} = \frac{W \times 192^3}{192 E . \frac{6 \times 8^3}{12}} \times \frac{W}{2}$$

$$1680\text{in.-lb.} = \frac{W^2 \times 192^2 \times 12}{2 \times 6 \times 8^4 \times E}$$

$$W^2 = \tfrac{140}{3} \times E = 46 \cdot 6 \times E$$

$$W = 6 \cdot 85 \sqrt{E} = 6 \cdot 85 \sqrt{1{,}700{,}000} = 2{,}870\text{lb.}$$

Therefore force of the blow is equal to a dead weight of 2,870lb.

$$D = \frac{W l^3}{192 E I} = \frac{2{,}870 \times 192 \times 192 \times 12}{1{,}700{,}000 \times 6 \times 8^4}$$

Deflection = ·243in.

Lasswade. J. WIGHT.

[97448.]—**Soap.**—Clarify your fat by beating it up one or two or three times. All smell will be gone.

G. A. HAIG.

[97454.]—**Overtype Dynamo.**—Drum armature, 7in. diameter 9in. long; C.I.F. magnets, 8in. by 9in. section; winding spaces 9in., wound with 50lb. No. 18 for shunt, 25lb. $\frac{7}{16}$ cable for series. Armature to have one layer 150 wires, No. 13. Speed about 1,200 per minute.

WEBSTER MICHELSON AND CO.
Eve Hill Works, Dudley.

[97456.]—**Launch.**—Many thanks to Mr. W. J. Shaw for his reply to my query. Would he, or someone else who knows, kindly inform me whether the method suggested of bringing the propeller-shaft out by the side of the stern-post, instead of through it, is a practical one, and would the screw act as efficiently (seeing how very slightly it would be out of the centre) as it would if it were placed in the centre of the stern-post? Having the boat, I wish to avoid altering her after-body, if possible. Hints as to method of fixing the shaft and tube, so as to make a watertight job, would be greatly appreciated. I observe that one maker advertises an engine (oil), ½H.P. for £10, while another asks £30 for one of similar power, the cheaper make being advertised by presumably a reliable firm. Wherein lies the difference to account for the great difference in price? I should also like details of jointed screw-shaft.

NAVIGATOR.

[97464.]—**Shortest Day in Trinidad.**—In Trinidad, as everywhere in N. latitudes, the shortest day is at Winter Solstice (generally Dec. 21). The length of the day (sunrise to sunset) in Trinidad on June 21 is 12h. 40m., on March 20 and Sept. 22 12h. 5m., and on Dec. 21 11h. 30m. Measuring from the beginning of dawn to end of twilight, the length of day is: June 21 15h. 18m., March 20 and Sept. 22 14h. 26m., Dec. 21 14h. 3m. When sun's declination is 20° S. (i.e., about Nov. 21 and Jan. 21), the length of day is 11h. 36m., or, including twilight, 14h. 5m. Thus including twilight does not make the day shorter in latter half of November than at Winter Solstice, although the difference is very small. In computing the above I have allowed for refraction, and considered twilight to end when the sun has sunk 18° below horizon.

ARCTURUS.

[97465.]—**Carbon Transmitter.**—Deal is a kind of pine, and except in not being generally quite so even in the grain, will serve just as well as Swiss pine. Choose a piece free from knots, with the veins running straight, and you will get good results. But you should have no difficulty in getting a bit of pine from any carpenter or builder. Remember it must be planed very thin.

S. BOTTONE.

[97465.]—**Carbon Transmitter.**—Deal will do quite as well for this form of transmitter.

S. ELLIMAN.

[97466.]—**Torpedo Boat Destroyer.**—There is generally a model on view at the United Service Museum in Whitehall. Admission 6d., except on Wednesday, when closed to public.

RUSHLIGHT.

[97467.]—**Rook Rifles.**—Neither the "·22 long" nor "·22 short" are satisfactory. The first is inaccurate and the second has a very high trajectory. The "·22 long rifle" of Union Metallic Co. is the most accurate, but its trajectory is too high. I prefer the Winchester ·22-7-45, which has a lower trajectory that the above. The stopping power is sufficient, particularly if hollow-pointed bullets are used, if the aim is reasonably good. I seldom fire at a rabbit beyond 80 yards, but have no claim to be considered a crack shot. With all the ·22 cartridges the trouble of keeping the rifle clean and free from rust is so great that I would be inclined to recommend the ·250 c.f., unless the querist has considerable capacity for taking pains. A repeater is not to be recommended if rabbits are to be stalked. With a rifle that can be loaded silently one may, if well hidden, frequently fire three or four shots in succession before they take the alarm, but the clank of the magazine sets them off at once. If a repeater is decided on, the Winchester is a good one, though probably no better than the Colt or Marlin. Have the "take down" model in any case. For rooks I prefer the ·300, not that any of the ·22 cartridges will not kill a rook if well placed, but many shots have to be taken through leaves and twigs which deflect the light bullet, and various causes, such as swaying branches, constrained position in aiming, and fatigue consequent on firing a large number of shots, militate against accuracy. Any of the ·22 cartridges will send their bullet clean through a rabbit, and, excepting perhaps the "·22 long," will shoot closer than any one who is not an expert can hold.

S. F. W.

[97467.]—**Rook Rifles.**—In my opinion, the ·22 rifle is not of much use for sporting purposes, as the hole it makes is not large enough to kill quickly, unless the game is struck in a vital place, and rabbits and rooks will go away merrily when drilled through the body to die afterwards. I have not found much difference between the long and short ·22 cartridge, and think that the former shoots quite as well as the latter, and ejects more easily. All these very small bore rifles foul badly after a dozen or two shots, and want much care in keeping clean. They also are much influenced by windage. The effective range is about 60yd. to 80yd., although I have hit tin pots several times running at 100yd. with good ones in calm weather. For practical purposes I prefer the Winchester ·320, which has a flat trajectory, and will kill nicely at 300yd. Next to this comes the ·295, a good rifle, but with a high trajectory, which makes it difficult to hit anything over 100yd. unless the range is known nicely. It stops nicely if it strikes anywhere near the head or shoulders of rabbits. Both these latter rifles are dangerous if used in populous places, as, indeed, are any rifles when used near places in which human beings are wandering around. I once put a bullet into a man at 500yd. with a ·22.

A. C. PEMBERTON.

[97468.]—**Protecting Steel Surfaces.**—I do not know the oxidising process; but could not "F. L. H." get his rods and pins nickel-plated.

JEFF.

[97470.]—**Motor-Cycles.**—Ball-bearings for the back axle of tricycle can be obtained from Wm. Bown, Ltd., Birmingham, or the Southern Motor-Car Co., 59, Brixton-road, London.

THE WRITER OF THE ARTICLES.

[97473.]—**Pocket Accumulators.**—Pitch is generally used for sealing in the tops.

A. H. AVERY, A.Inst.E.E.
Fulmen Works, Tunbridge Wells.

[97473.]—**Pocket Accumulators**—Pitch, or Prout's elastic glue.

S. BOTTONE.

[97474.]—**Knocking in Gas-Engine.**—You had better heat the tube further from the cylinder. The new rings are not yet worn to the cylinder—they will be all right in time.

Dudley. WEBSTER MICHELSON AND CO.

[97474.]—**Knocking in Gas-Engine.**—The symptoms seem to point either to too early firing or too rich a mixture of oils, gas, with air. Try sliding the ignition chimney up a little, and decreasing the oil supply. Of course, I presume that all the bearings are tight—no back-lash. When running, the piston should be tight enough to prevent any visible escape of the products of combustion.

A. C. PEMBERTON.

[97474.]—**Knocking in Gas-Engine.**—If "Country Parson" will fit a longer ignition-tube in his engine, or heat the present one higher up with his Bunsen flame, that would cause the charge in cylinder to be fired later. Apparently the charge is fired or ignited before the crank has just turned the back centre, thereby causing a great shock and consequent strain on the working parts. The best results in this direction are obtained by a little experimenting, a good deal depending on the speed the engine has to run, &c. Another cause of a thumping noise in a gas-engine is that sometimes the flywheel key becomes a little loose from the strain put upon it by every impulse. This defect alone would soon ruin the finest engine made.

H. WILSON.

[97474.]—**Knocking in Gas-Engine.**—Is your ignition right? Try the burner higher, but not so high as to make engine miss fire. The explosion getting past the piston-rings would probably cause some noise.

SENLAC.

[97474.]—**Knocking in Gas-Engine.**—Gas-engines will sometimes make a knocking noise if the air and gas are in wrong proportion. It should be 1 to 8; also, if the tube is heated too low or too high. It must be red-hot, not white-hot. See that your valves are properly timed with the crank; exhaust should start opening at the commencement of the last half of the second revolution, and shut almost at the end of second revolution.

IGNITION TUBE.

[97474.]—**Knocking in Gas-Engine.**—This arises from the rings not fitting. Probably they are too loose in the grooves, or the grooves may have worn unequally—holding the rings tight at one side and allowing them to rattle at the other. In which case, the grooves will have to be tried up in the lathe and wider rings fitted.

Bromley, Kent. A. F. SHAKESPEAR.

[97474.]—**Knocking in Gas-Engine.**—If "A Country Parson" will take the rod out of the piston, and give the cogwheel which regulates the gunmetal bearings a slight turn (one cog will be sufficient), at same time cleaning all lubricating holes, he will doubtless find that the knocking will cease. The bearings wear out and require occasional tightening, especially if the lubricating holes are clogged.

C. J. L.

[97475.]—**Telephones.**—The fault is probably due to the fact that your microphones are lying horizontally, so that the carbon grains sometimes do not touch both diaphragms. Suspend them horizontally; preferably by twin flexible cords, so that they can be shaken up from time to time. This will probably remedy matters.

S. BOTTONE.

[97476.]—**Soldering Carbons.**—Make up a cell of a porous pot in an outer containing jar. In the porous pot place water acidulated with sulphuric acid, in the outer jar a saturated solution of copper sulphate. Place a rod or strip of zinc in the porous pot and attach the carbon thereto by a short length of wire. Allow about ¼in. of the carbon to dip into the copper sulphate, and in a short time it will become coated with a skin of copper, and may then be readily soldered. Or make a little mould, and having cut a few nicks in the carbon, cast a lead cap on. A little antimony added to the lead will tend to give it a better grip.

W. J. G. FORMAN.

[97476.]—**Soldering Carbons.**—Carbon is coppered first. Immerse in a strong solution of sulphate of copper to the depth that is required coppered; make the carbon the cathode, and insert a copper plate in the solution to form the anode. Pass current through this cell at a voltage of about 3 or 4 volts, and when a good deposit has been obtained take out the carbon, rinse, apply a flux, and tin thoroughly in the usual way, taking care to have everything ready and close at hand, as the pure deposit of copper tarnishes so quickly if exposed to the air.

A. H. AVERY, A.Inst.E.E.
Fulmen Works, Tunbridge Wells.

[97476.]—**Soldering Carbons.**—The usual method of connecting brass terminals to carbon plates is to run molten lead about the ends of the plates and the terminals in a mould, not by soldering.

JEFF.

[97476.]—**Soldering Carbons.**—Carbon must be copper-plated. This may be done by placing carbons and copper-plate in saturated solutions of copper sulphate, join positive lead of Daniell or Bunsen cell or battery to copper-plate, and negative lead to carbons. Place copper-plate close, but not touching carbons in solution.

A. BOTTING.

[97476.]—**Soldering Carbons.**—The carbon block, plate, or stick must be copper-plated before you can solder it. This can be done easily as follows:—Make about 1 pint of solution of sulphate of copper, and add about 1oz. sulphuric acid. In this place a zinc rod or plate, the wire from which twist round the end of carbon plate. If the other end of carbon is now dipped in the solution, it will be covered with a film of copper in a few minutes, which can be soldered in the usual way.

SENLAC.

[97476.]—**Soldering Carbons.**—To do this a coat of copper is first electro-deposited on the carbon.

It is then quite easy to solder any wire, &c., to it. A single cell arrangement will do.
West Didsbury. M. COLE.

[97476.]—**Soldering Carbons.**—You cannot tin carbons without previously coating the ends with copper, deposited from its solution as sulphate, by means of a Daniell or other suitable battery, as frequently described in these pages. S. BOTTONE.

[97477.]—**Brasswork.**—You can clean brass and copper beaten work by lightly rubbing with soft towel dipped in a weak solution of oxalic acid (poison), then drying with fresh dry waste, and polishing with chamois and finest rouge. To preserve from tarnishing, the work must be lacquered, with lacquer of suitable colour, or varnished with a clear varnish of celluloid, in benzole or amyl-acetate—preferably in benzole. S. BOTTONE.

[97478.] — **Electric Light and Gas.** — Gas at 3s. 8d. per 1,000. A standard gas-jet consumes 8ft. per hour, hence 1,000ft. supplies same for 125 hours at a cost of 3s. 8d. A unit of electricity equals 1,000 watts. A 16 c.p. lamp requires 60 watts per hour, hence such a lamp takes 7,500 watts, or 7½ units, in 125 hours, and, at a cost of 5·9d. per unit, equals the cost of gas. I have been running a 5½ unit dynamo, compound-wound, for the past 18 months with a 6H.P. gas-engine—gas at 1s. 9d. per thousand—and my estimate from careful observation is that the actual cost per unit (gas consumption only) is a shade under 1½d. per unit.
Plymouth. E. H. MICKLEWOOD.

[97478.] — **Electric Light and Gas.** — The answer is 3⅞d. A. H. AVERY, A.Inst.E.E.
Folmen Works, Tunbridge Wells.

[97478.]—**Electric Light and Gas.**—Since it must be very good gas that will give 12 candle-power light for every 5c.ft. of gas consumed per hour, it follows that 1,000c.ft. = 2,400 candle-power per hour, at a cost of 3s. 8d. Now, 1 unit of electricity = 1,000 watt-hours, and each candle-power requires 3·5 watts per hour to maintain it. Hence 1,000 watts = 285 candle-power, and 285 into 2,400 go 8·45 times. Therefore about 8½ units of electricity would be wanted to give the same light as 1,000c.ft. of gas. At 5d. a unit the price would be slightly in favour of electricity, since 8·45 × 5 = 42·25, or, say, 3s. 6¼d. In many places electricity is supplied at a lower rate than this.
S. BOTTONE.

[97478.] — **Electric Light and Gas.**—Electricity at 3½d. or 4d. per unit would be equivalent to gas at 3s. 6d. to 4s. per 1,000c.f., if the gas is of the usual 16c.p. quality. See last page of our new catalogue.
Dudley. WEBSTER MICHELSON AND CO.

[97479.] — **Induction Coil.** — (1) Yes, with a properly-wound Tesla, proportioned so as to increase the voltage six times. Of course, the spark loses density in like proportion, and becomes very thin and wiredrawn. (2) No, there is nothing new about these coils; some are still made, and I believe Watson's, of Holborn, still stock them. (3) A "tank" coil, immersed bodily in a tank of linseed-oil, works very well. Paraffin-oil is not so good; but the heavy petroleum-oil used for vaseline is excellent. S. BOTTONE.

[97480.]—**Chlorine and Fluorine.**—1. Fluorine has been obtained by the action of dry iodine upon dry silver fluoride. It is a transparent colourless gas, which, when dry, does not act on glass. It is absorbed by caustic potash, with the formation of potassium fluoride and hydrogen dioxide thus—

$$2KHO + F_2 = 2KF + H_2O_2.$$

2. Chlorine has been liquefied at a pressure of four atmospheres. I believe it has not yet been solidified, but should imagine liquid air would do it.
S. BOTTONE.

[97483.] — **Stains for Gun-Barrels.** — To "MECHANIC."—**Browning**: Solution of spirits of nitre ¾oz., black brimstone ¼oz., blue vitriol ¼oz., corrosive sublimate ¼oz., nitric acid 1dr., copperas ¼oz., rain-water 1½ pint. Mix and bottle for use. Clean bright with finest emery paper; then apply solution with clean white cloth. Set away for 24 hours. Then scratch-brush rust off formed, and rub off with woollen cloth. If not brown enough, repeat. If colour suits, wash off with wet cloth, rub thoroughly dry, finish by rubbing with linseed oil to prevent further rusting. Or sulphate copper 1oz., sweet spirits of nitre 1oz., water 1 pint; mix. In a few days ready for use. Two out of thirteen for browning. Bluing: Clean with emery paper, and quickly go over them with nitric acid. When desired colours are obtained, wash off with linseed-oil. See Stelle and Harrison's "Gunsmith's Manual," published by J. Haney and Co., New York. REGENT'S PARK.

[97484.]—**Lens Problem.**—With an iris diaphragm opening gradually the light passed at any given moment is of course dependent on the area of the opening at that moment. These openings could be graphically represented by slices (sections) taken off a solid cone at equal distances. The openings, when the lens was open all the time, could in a similar way be represented by slices from a solid cylinder of equal height and diameter of the cone. Now a solid cone has one-third the cubic contents of a solid cylinder the same height and diameter, therefore, provided the motion of the inner edge of the diaphragm were uniform, the exposure during the time an iris opens from nothing to full opening is one-third that given if the iris were open all the time. It will be a nice little task for "Iris" to ascertain whether the edge of the diaphragm moves uniformly when the iris ring is revolved uniformly. I do not think there is a great deal of difference, and therefore that the one-third exposure is approximately correct. ALFRED WATKINS.

[97485.]—**Sparking Coil for Motor-Car.**—Primary, 1lb. No. 16 d.c.c.; secondary, 1lb. No. 34 double silk-covered. S. BOTTONE.

[97488.]—**Soap.**—Add such ingredients as lanolin, vaseline, spermaceti, in about 5 to 10 per cent. of weight of soap. Brown Windsor proportions: 75lb. of soap or tallow and palm oil, 2lb. palm oil, 1lb. mirbane, 1oz. Bismarck brown. White kind: 75lb. of white soap of tallow and cokernut oil, 3lb. cokernut oil, 1lb. citronelle. See G. H. Hurst, F.C.S., on "Soaps" (Scott and Co., Trade Journal Publishers, Ludgate Hill.) REGENT'S PARK.

[97490.] — **Motor - Car Carburettor.** — "F. W. B." will find a carburettor, such as he requires, fully described in the Motor-Car articles now appearing, in its proper sequence.
THE WRITER OF THE ARTICLES.

[97494.]—**Shanks Patent Bath.**—The way to lift the porcelain soap-dish is to take off the water handles. Have you not omitted to loosen the little jamming screws at the side of the handles? The two water-handles should be unscrewed, and the flanges below them which hold the dish down, when the dish will be found to lift away, bringing with it the combined overflow pipe and waste plug. Beware of shortening the wire of the waste plug overmuch. My experience is that unless the pipe is allowed to cant a little the valve will not be tight. When you get the dish off you will understand what I mean. W. J. G. FORMAN.

[97496.]—**Silicate of Alumina.**—There are a great number of silicates of aluminium—many of them being common and well-known minerals. Clay is silicate of aluminium. Kaolin or porcelain clay has the formula $Al_2O_3 2SiO_2 2H_2O$. This clay results from the decomposition of orthoclase, another silicate of aluminium $K_2OAl_2O_3 6S.O_2$. Staurolite, often known as slate crystals, and often of great beauty, is a silicate of aluminium, frequently combined with iron and magnesia. Andalusite, kyanite, and allophane are also silicates of aluminium. Flint is practically pure silica, so that any of the above might be correctly described as a combination of aluminium and flint.
W. J. G. FORMAN.

[97496.]—**Silicate of Alumina.** — Occurs in nature in the following minerals and earths, some of which you can get cheaply:—Allophane, alumstone, collyrite, wörthite, miloschine, porcelain clay from Passau, cimolite, or Ellenbogen kaolin, agalmatolite, bucholzite, xenolite, ordinary porcelain clay, andalusite, chiassolite, cyanite, or kyanite, fibrolite, sillimanite, razoumaffskin, and malthacite Even the darker-coloured clays are nearly pure silicates of alumina, with small admixtures of iron and calcium. In fact, the aluminic silicates constitute the greater part of the earth's crust.
S. BOTTONE.

[97497.]—**Carburator.**—See reply 97490 above.
THE WRITER OF THE ARTICLES.

[97498.]—**Gas-Engine.**—Presuming that you can't *start* your engine on account of its firing back, then a probable reason is that the bearings and working parts are so tight that you can't get up a decent speed before admitting the charge. I always notice on turning my engine slowly that it invariably fires back if the compression be good. Should ignition still take place before the end of stroke, try heating tube a little higher, say ½in., and if unsuccessful, try a longer tube. To prevent exhaust being drawn back into cylinder, use a stronger spring. You say you have done so. Well, use a stronger one still. A very high compression is not necessary, but if piston and valves don't leak, then you can hardly avoid it, can you? You don't get too much gas and air into cylinder provided that they are in the correct proportions, for since they are sucked in automatically the pressure can't rise above the atmosphere, and it will probably be slightly below it at beginning of compression stroke. Two flywheels 8in. diam. are large enough.
W. EWART GIBSON.
103, Ferry-road, Leith, N.B.

[97498.]—**Gas-Engine.**—Engine fires its charge too soon, and so reverses. This is a very usual trouble with engines having no timing-valve, and in which the flywheels are so light that sufficient forward momentum cannot be got on them. There are several remedies. One is, fit a timing-valve by which the compressed explosive mixture is admitted to the firing-tube at a given position of the crank, and if this can be varied so as to fire earlier when once speed as been attained, so much the better. A simple plan is to heat the firing-tube higher up, as this will usually retard the time of firing the charge. Another plan is to fit a handle to end of shaft notched in such a way that when the engine fires it overruns the handle. By this means momentum sufficient to start it can be given. As to sucking back exhaust gases, these small engines usually exhaust right into the air, in which case the valve acting as a snifting valve is no detriment. Still, if the air-and-gas valve open soon enough, there should be little or no tendency for this to happen. High compression stops engine completely. It is impossible to have too good a compression in a gas-engine, and you cannot get in too much gas and air. The whole of the trouble arises from the lightness of the flywheels and consequent trouble in starting.
Plymouth. E. H. MICKLEWOOD.

[97498.]—**Gas-Engine.**—Without knowing the weight of the flywheels it is difficult to say if they are large enough. As a basis, I may say that one wheel 14in. diameter, weighing about 30lb. or 40lb., would do for this engine nicely. Of course, if the air-tap is turned off, the engine will suck back the exhaust. It should be left wide open, and the regulation done with the gas-cock alone—there is no need for an air-tap at all. The high compression is an advantage. All these small engines should fire early, and to start them they want a good spin, which is best given by pulling them round with the belt on the driving pulley. If they are timed to fire correctly when starting, they will lose much power when running at proper speed, say, some 500 revolutions per minute. The engine can be readily altered to fire later by sliding the chimney up a little.
A. C. PEMBERTON.

[97498.]—**Gas-Engine.**—Try heating the tube higher up—that is, away from cylinder. In such an engine as David Barratt describes, ⅛in. gas-pipe makes a good ignition tube, and lasts a long while. Are the valves set properly? Exhaust should open just before end of firing stroke, and remain open till piston reaches the top or end of cylinder again, but not later, or exhaust mixes with charge. If valves are right, stronger spring must do it. The piston can only suck 14·7lb. per square inch, so if area of exhaust-valve is known, you can easily find how strong your spring must be. If the engine is in London, I will gladly see and advise. You can have too much compression, but that is hardly likely to be your trouble. H. SCOTT RUSSELL.

[97498.] — **Gas-Engine.**—Your ignition-tube should be about 8in. long, made from a piece of ⅛in. gas-barrel. It should be bright red, about 2½in. from the bottom. If the tube is heated too low—not hot enough—the charge explodes too soon. If there is no explosion the tube is heated too high. The exhaust-valve should be pretty strong, as it is intended to be moved by gear from the crankshaft. It is a mistake to have the compression too high. Compression to 60lb. per square inch is high enough. The gas and air is 1 of gas to 8 of air. Your flywheels are much too small; use a pair of flywheels at least 12in. in diameter, weighing from 28lb. to 40lb. each; the crankshaft being ⅝in. in diameter. IGNITION TUBE.

[97498.]—**Gas-Engine.**—Your trouble is probably with ignition. Try a tube of ¼in. gaspipe, 5in. long, and heat about half-way up. If it still fires too soon, raise burner higher. The exact height will largely depend on the speed you run the engine at. If your exhaust valve is sound, try a stronger spring. You do not say weight of flywheels, so cannot advise; but they seem too small.
SENLAC.

[97499.]—**To Mr. Bottone.**—Since an impression on the retina lasts at least $\frac{1}{10}$th of a second, a succession of light-waves following each other at the rate of 44 waves per second would so overlap each other as to produce practically the same effect on the eye as one continuous light. But the alternating light is generally produced by much more rapid alternating, 80 to 110. S. BOTTONE.

[97500.]—**Cutter-Bar for Slide-Rest.**—C. W. Hull should get Smith and Coventry's tool list. Their holders for round tool steel are especially handy for general work. I have never known the steel to slip whilst taking even very heavy cuts.
JEFF.

[97500.]—**Cutter-Bar for Slide-Rest.**—I have recently purchased from the Pittler Company a tool-holder with tools for general slide-rest work of very novel and ingenious design. The cutters only require grinding on one face, and the movements are such that any clearance angle can be readily obtained. It is much more readily used on a lathe with adjustment for height of tool-post than on one where packing-pieces are required, and it can only be ground on an emery-wheel, which should not be more tha ¼in. thick. Given these conditions, it is a first-class idea for all sorts of outside turning.
Plymouth. E. H. MICKLEWOOD.

[97500.]—**Cutter-Bar for Slide-Rest.**—I have been using the Britannia Co.'s "Climax" bar for

the last eighteen months, and am very well satisfied with it, as it is suitable for both ordinary turning and screw-cutting. The other bars I have are not satisfactory; they may be all right for small lathes, but mine range from 7-centre upwards. The Haydon bar is very well for non-screw-cutting jobs, but wants to be very nicely made, or the cutter slips.

Bromley, Kent. A. F. Shakespear.

[97501.]—**Breech for Model Cannon.**—No simpler form than that used for cheap rook rifles, which may be seen in the windows of any gunsmith.

West Didsbury. M. Cole.

[97504.]—**Electrical.**—This query is a little ambiguous, as it is not stated whether one cell only is to be in circuit at a time, or one to be cut out and nine left in circuit. Supposing the former to be what is required, take a piece of dry board, say about 18in. long by 2in. wide. Attach to it ten little squares or circles of brass plate. Bore a hole in the centre of each plate, and provide a conical brass plug to fit the holes. Place two terminals about the centre of the board. To one of them attach the brass plug by a sufficient length of flexible wire. To the other terminal attach all the zincs of the ten cells and attach the carbon of each cell to one of the brass plates. The outer circuit will start from one terminal and end at the other, and by placing the plug in one or other of the brass plates, any given cell can be thrown alone into action. W. G. J. Forman.

[97504.]—**Electrical.**—Arrange your ten cells in a circle. Connect them in series, bring each pair of a connection out on the upper surface of a circular board, in the centre of which is pivoted a brass arm, which can be revolved so as to touch these connections. These connections should, for convenience of contact, be fastened electrically to brass studs arranged round the board so that the lever-arm can pass freely from one to the other. One terminal is fixed in permanent connection with one pole of the battery, the other is connected to the rotating brass arm. S. Bottone.

[97507.]—**Frame Food**—The following is the report of Mr. Alf. W. Stokes, the well-known analyst, on Frame Food, dated March 10, 1897: "I find it to contain in 100 parts by weight: albuminoids 16·30, sugar and dextrine 28·60, carbo-hydrates 53 00, mineral salts 1·55, moisture 0·55. The mineral matter consists principally of phosphate of potash, with compounds of lime and iron. The microscope showed that almost the whole of the starch granules were broken up, so that they are in condition to be immediately acted upon by the saliva and gastric juice. No fungus or other extraneous material could be detected. There was an entire absence of all preservatives. Having regard to these facts, I am of opinion that this is a prepared food of high dietetic value. Its richness in albuminoids and phosphates, and its readiness for easy assimilation, render it a valuable addition to our scanty stock of foods especially fitted for the use of children and invalids, and of infants of delicate digestion. Taken with milk, it would supply the whole of the nutritive ingredients required for the maintenance of vigorous life and health. It has been so prepared that about half of the material is soluble in cold water, and is, therefore, to that extent no tax whatever on the digestive organs. In the case of ordinary bread, as dry material, only about 10 per cent. is thus soluble. While bread contains usually some 40 per cent. of moisture, this 'Frame Food' Diet contains only half of one per cent. Hence, the latter is a more concentrated form of food." I believe your querist can obtain a free sample, if he mentions this paper and applies to the Frame Food Co., Battersea, S.W., and incloses three penny stamps for postage. I have found it palatable, digestible, and invigorating myself. Senex.

[97508.]—**Dead Batteries.**—Take off the terminals, make a hole through the pitch, near the carbon plate, with a hot stair-rod, pushing it down till you reach the paste inside. Now stand the cells in a wooden pail full of water for 24 hours. Remove, and stand upside down to drain a little. Prepare a saturated solution of permanganate of potash, and squirt as much of this in each cell as it will take up. Seal up the pitch again with a hot iron, clean up the terminals, and replace on the cells. S. Bottone.

[97511.]—**Radiometers.**—Rays of heat pass through the glass (without heating it) and impinge upon the blackened vanes. These are heated, and in turn also are heated the residual molecules of air left within the globe after exhaustion. The air-molecules fly from the hot vanes to the cold glass, where they are chilled and their velocity slowed down; thus a sort of bombardment is set up in front of the blackened vanes. There is a similar action going on at the back of the vanes, but in a lesser degree, as there is here less heat. The excess of bombardment on the heated or blackened side of the vane causes its retreat. Brandon T. Brierley.

[97512.]—**Manchester Dynamo.**—To Mr. Avery.—Armature 12 cog ring 4in. diam. by 2in. long, wound with 2lb. No. 22; field cores 1½sq.in. section by 4in. long, wound with 8lb. No. 22, connected in shunt. A. H. Avery, A.Inst.E.E.

Fulmen Works, Tunbridge Wells.

[97515.]—**Water Wheel.**—The theoretical horse-power given by the quantity and pressure of water stated would be about 2·1H.P. A turbine will return about 70 per cent. of this as effective horse-power—i.e., about 1½H.P. The velocity of the water at the pressure stated will be rather over 10,000ft. per minute. The velocity of the "circle of effort" of the turbine will be rather more than half this speed, say 6,000ft. per minute. To bring the dimensions of the wheel in line with this speed at 30,000 revolutions would mean a diameter of something like ½in., which is of course quite out of the question. Better keep the speed down to about 6,000 revolutions. This will give a wheel of about 3½in. diameter, inlet nozzle ¼in. diameter.

W. J. G. Forman.

[97516.]—**Edison-Lalande Battery.**—To Mr. Bottone.—As the chemical affinities of sodium are not so powerful as those of potassium, in the proportion of two to three nearly, so the battery will be weaker with the caustic soda as an excitant. The reaction consists in the formation of an akaline zincate, with the liberation of hydrogen, which in its turn absorbs oxygen from the copper dioxide plate, and is converted into water. Taken altogether, and for the special work you require, the Lalande is the better battery; but it is bulky, and has but little E.M.F. The accumulator is the best, if you have access to a charging station.

S. Bottone.

[97517.]—**Propellers.**—Sir W. A. White, in "Naval Architecture," gives pages on slip, both of paddle and screws. He gives, p. 607, (1) the mean effective angle of screw-blade, measured from an athwartship plane or pitch-angle, should be 45°, obtained when pitch is about twice extreme diameter. (2) Slip-angle varies directly as square root of coefficient of friction, and inversely as square root of coefficient of normal pressure, which gives a slip of about 12½ per cent. with the values of coefficients adopted. This is the real slip, apparent slip usually less, and varies to the amount and character of disturbance of water in which screw works. (3) Area of screw-blades may be expressed by formula—

$$\text{Area (in square feet)} = 8{\cdot}9 \times \frac{R}{v^2}$$

where R = resistance of vessel (in pounds) at her maximum speed v (in feet per second). (4) Since at moderate speed resistance varies as square of speed, same propeller should, within those limits of speed, drive ship with same percentage of slip; but above those limits of speed percentage of slip should increase. (5) For moderate speeds, if blade areas of screws of two similar ships have the ratio of squares of respective dimensions, the percentage of slip should be the same. (6) If two ships have same resistance at different speeds, area of screw-blades, which will overcome resistance, while maintaining given slip, will be less, in ratio of squares of speeds for ship which has higher speed; the last three deductions obtained from formula for blade area; or, suppose screw carried forward through undisturbed water at speed V feet per sec., mounted ahead of a suitably designed framework. As it advances let it be rotated N times per sec., if mean pitch be p feet. Speed of an advance of screw = V; speed of screw corresponding to revolutions and pitch $= V_1 = Np$; "slip ratio" screw $= \frac{V_1 - V}{V_1}$; slip of screw (per cent. of its speed) $= \frac{V_1 - V}{V_1} \times 100$. Example:—Screw making 72 revs. per minute, with pitch of 14ft., speed of advance being 8·2 knots. Speed of advance ft. $= V = 8{\cdot}2 \times 1{\cdot}688 = 13{\cdot}8$ per sec.; speed of screw $= V_1 = \frac{72 \times 14}{60} = 16{\cdot}8$; slip of screw $= V_1 - V = 3$; slip ratio of screw $= \frac{V_1 - V}{V_1} = \frac{3}{16{\cdot}8} = \frac{1}{5{\cdot}6}$; slip of screw (per cent.) $= \frac{3}{16{\cdot}8} \times 100 = 17{\cdot}85$ (1894 edition). Regent's Park.

[97518.]—**Clock-Weight.**—To "Antares."—I do not wonder at your surprise at the extraordinary information received from the two local clockmakers, for if the case was as stated by them, their own regulators ought to be swinging large arcs with a weight of an ounce or so. You will find, on reference to any work on escapements, that the dead-beat is, when properly constructed and the oil in fair state, very sensitive to any variation in the motive power, and that an increase of motive power is speedily followed by an increase of arc. This is remarked by Reid, page 189; by Sir Edmund Beckett, in any of his editions of "Clocks, Watches, and Bells"; by Charles Frodsham, in his masterly essay on the "Dead-Beat Escapement," printed in the *Horological Journal* for March and July, 1886; by Glasgow, in his "Watch and Clock-making"; and in Britten's "Watch and Clock-maker's Handbook." So if that is the experience of the best artists of the last hundred years or so, one must accept any statement to the contrary with a certain amount of reserve. I know my own Graham escapement regulator gives the following results:—With 3lb. it vibrates just over 1 degree, with 4lb. 1½ degree, with 6½lb. 2 degrees; and another clock with same escapement, going a month and driven by a weight of 12lb., will not go at all with only 6, the arc falls off until the clock fails to escape. But one can imagine it is possible that if the weight were excessive and the pendulum rather light, together with very thick and gritty oil on the resting faces of the pallets, that a reduction in weight might bring about an increase of arc. But such conditions would be quite abnormal. Of course, with escapements of a remontoire or spring pallet description the case is altered, for in that case so long as there is power enough to "arm the maintainer," as the expression is, any extra can only resist the unlocking, though in such an escapement as the Beckett gravity it is insensible. But Reid, on page 199, gives an example of one of his fine old spring-pallet clocks where an addition to the weight caused a decrease of arc, as might have been expected, the extra power giving nothing to the pendulum, whilst making the unlocking decidedly heavier. But experiments on that plan are quite extinct now, and only met with in old clocks; so if "Antares" will clean and oil his dead-beat, he will find that by doubling the weight that he will get a very decided increase of arc, though if the escapement is correctly planned, the alteration of rate will be slight. F. M. Mann.

[97520.]—**Cataloguing Books.**—You have not stated if the library is liable to increase or the class of persons who are to use the catalogue. A card catalogue is much the easiest to alter if the collection grows; but many people of disorderly habits cannot be intrusted with one, in which case a book must be used, and growth allowed for by leaving blanks between the entries, which are more or less of an eyesore when partially filled up. The first point in cataloguing is the arrangement of the books. A convenient arrangement for a public library consists in placing the books alphabetically under authors; but this is about the worst for a private library. The proper way is to group under subjects, the books in each subject being arranged alphabetically according to authors' surnames. The division into subjects is one of the most troublesome points in cataloguing, and it is very difficult, without actually seeing the books, to give advice on it. The division must not be carried very fine. Seven or eight sections ought to be ample for any collection containing only 1,500 volumes. A tolerable division for a general library would be: History, biography, travel, fiction, poetry, general literature, science, theology, and works of reference. It would break down, of course, in the case of any collection of a special nature. It is a current maxim, however, that a special student who cannot carry two thousand book-titles in his head is not worth his salt, and that all he really wants is some means of registering the borrowings of his friends. As regards the placing of the books, all works of reference, such as dictionaries and atlases, should stand on shelves between 2ft. and 3ft. above the floor, so as to be in the most convenient position for consultation by a sitter. The side of the fireplace will be best for them. Very high shelves and very low ones, should be given up to works on subjects of little interest. There is no reason why any important book in a library of only 1,500 volumes should require either uncomfortable stooping or the use of a ladder. The books on any subject of interest should stand on shelves not less than 2ft., or more than 6ft., above the floor; 5ft. 6in., in fact, is quite high enough, if ladies are to take down the books. The use of ladders or stools adds enormously to the fatigue of literary work. The books being grouped on the shelves, the next thing is to number them. A library which does not increase may be numbered from 1 up to 1,500, proceeding regularly along the shelves, preferably from left to right. Small suffix letters would be added to the numbers in marking the separate volumes of a large work. The only way of dealing with additions on this system is to put them at the tail-end of the series of numbers. A more adaptable way, however, is to assign a capital letter (or pair of letters after the 26th) to each shelf-compartment, and number the volumes in each compartment from 1 to the highest in it. Each volume would then be indicated by a capital letter and a number, with a small suffix letter following in the case of a work of several volumes. Thus, the indication for the third volume of Smiles's "Lives of the Engineers" might be "B B 24 c," meaning that it would be found in the 28th compartment at 24 places along it. Many people, however, cannot be got to understand this system of numbering, in which case there is nothing for it but to fall back on the plan of a running series. The next thing is the making of the catalogue. See that all the books are in; do not depend on your remembrance of those which are absent, for you will make some awkward omission that will spoil the appearance of a page of your work. If you are going to

make a card catalogue, use well-glazed cardboard, cut to a uniform size, and placed in a long drawer with about an inch of margin in the width, a steeply-inclined plane at the back giving the cards a slant of about 60°. A convenient size of card is about 4in. wide and 3in. high. The entry on each card should run thus:—Author's surname, Christian name or initial, number of volume (conspicuously written on upper right-hand corner, preferably in red ink), title of the book (exactly as it is given on the title-page), editor or translator (if any), and subject heading. Let us take two cases, one where running numbers are used, and one where shelf compartments are separately labelled.

Renan, Ernest. 783
"The Future of Science."
Transl. by Vandam and Pitman.

Lyell, Sir Charles. Y 17 a b
Life, Letters, and Journals.
Edited by Mrs. Lyell.

The backs of the cards can be utilised for noting borrowers' names, and the dates of issue. The card catalogue requires to be supplemented by divisional lists, one for each subject, in which the authors' names in alphabetical order and the reference numbers are alone given. The compiling of an ordinary catalogue in book-form should be preceded by the making of what is virtually a card catalogue. About 1,600 slips of paper will be required, on which the same details must be noted as in the case of the cards. These are then to be sorted, with the surnames of authors in an alphabetical series. The entries will be copied from the pile as they now stand; the reference numbers, however, being placed in a column on one side of the page. An entry in the catalogue would run like this:—

Carleton, Will., "Farm Ballads" (poetry)..121

This catalogue will also require supplementary divisional lists of the authors on particular subjects. The book form of catalogue is not at all suitable for recording borrowing transactions. A separate volume should be provided, arranged under borrowers' names, opposite each of which the reference number and the date of issue of a work can be entered. It is desirable to place a private identification mark in at least three places in the text of each volume. This may be a conspicuous one made with a rubber stamp, or a bare indication executed with a pen. The main point is to adhere to the same pages for the insertion of the marks. The owner of a good collection of works of fiction would do well to resort to the rubber stamp. Careful librarians provide a number of strips of stout card to mark the places where volumes are absent. Some even go so far as to assign a special card to each borrower, but this is perhaps an unnecessary refinement. P.

It is stated that elephants' skins are tanned to make carpets. They never wear out, but are expensive.

Field Experiments with Manures.—Mr. W. T. Wood, of the Cambridge University Department of Agriculture, gave the results of several field experiments at a meeting of the Cambridgeshire and Isle of Ely Chamber of Agriculture, at Cambridge, recently. He said that rotation experiments had now been carried out at Hatley and at Thriplow for the past three years, and several valuable lessons had been learnt. The artificials used in each experiment consisted of a mixture of superphosphate, sulphate of ammonia, and sulphate of potash in the proportions of 5cwt. of the former to 1cwt. of each of the latter. The first plot started with 7cwt. of artificials for swedes, and each succeeding year 2½cwt., and had produced a considerable increase in the roots and also in the barley—35 bushels, as compared with about 21 bushels on the no-manure plot. The plot which had paid best at Thriplow was treated according to the local method—namely, to grow the swedes with a small dressing of superphosphates, to eat the swedes on the land with sheep getting cake, and not to put on any manure either for barley or for swedes. The plots which paid next best were those which had received dressings of dung, and those which had paid the worst were those which had received nothing but artificials. The reason why dung was not suitable for heavy land appeared to be that wet land was so tenacious that it did not allow the air to get in, and prevented the dung from rotting. In potato experiments, by using 4cwt. of superphosphates they had an increased average yield of 1 ton 15¼cwt. By increasing the dressing to 8cwt. they had produced a distinct increase in the aggregate on peat soils, but on silt soil no further increase had been obtained. On one plot the 8cwt. of superphosphates had given an increase of 2 tons 5¼cwt. The addition of potash had not been at all profitable. Apparently on black soil the manuring of potatoes resolved itself into applying a considerable amount of some soluble, quick-acting artificial, such as superphosphates. Thirty-five charlock spraying demonstrations had taken place, which went to show that spraying should be done on a fine day when there was very little wind.

UNANSWERED QUERIES.

The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered, are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.

Since our last "Glatton" has replied to 97069; R. A. R. Bennett, 97216, 97231.

QUERIES.

[97522.]—**Solution Wanted.**—Will some mathematical reader please give a general method for solving indeterminate equations like the following in positive integers?

$$16v + 13w + 9x + 21y + 5z = 17(v + w + x + y + z).$$

N.B.—This is *not* an examination question.—E. H. R.

[97523.]—**Curious Geometrical Figure.**—If a narrow strip of paper or other flexible material be taken and the ends joined, we have a cylindrical ring, with two distinct surfaces, an inner and an outer, and two distinct circular edges. If, however, before joining the ends we give the material a half-twist, we get instead a very curious figure, having only one surface and one continuous edge. What is the name of the figure so formed? And will some reader furnish a few particulars as to its properties, geometrical, mechanical, &c.?—E. H. R.

[97524.]—**Ancient Music.**—Can any reader of the English Mechanic inform me where I can obtain a copy of a piece of ancient Greek music, found in an excavation made to discover Greek antiquities some few years ago? It was, I believe, a "Hymn to Apollo," and was properly arranged and set for orchestral performance, and was actually performed in public at one of the large rooms in London.—Curious.

[97525.]—**Threshing.**—Kindly explain as concisely as possible the action of a modern grain-threshing machine, from the putting in of the straw and grain attached, to the finishing of the process, where the grain is taken away in sacks of different qualities. What I want to know is the different actions of the machinery. (1) The threshing. (2) Getting rid of the chaff and straw. (3) The separation of the qualities of grain. An answer to the above would greatly oblige.—Dutch Paul.

[97526.]—**Chalk Engraving Plate.**—I should be glad of any information as to the method of making chalk plates. The article in question is a thin sheet of steel, coated with a composition resembling French chalk. By means of a fine-pointed instrument a picture is drawn through the composition; the plate is then placed in a casting-box, and filled up with molten metal, which produces a printing block. The composition should crumble away under the point of the needle, but the intersecting portions between finely-drawn lines should remain standing. I have experimented with various substances, but failed to obtain anything like a satisfactory result.—W. H. S., Plymouth.

[97527.]—**Condenser.**—Will some expert steam-user inform me what form of condenser for a 250I.H.P. compound engine produces most economy in fuel, with a plentiful supply of cold water? Also, what is the best form in a similar case where water is scarce?—H. Jay.

[97528.]—**Power for Motor.**—I have two dynamos, shunt wound, 100 volts 40 ampères each. I want to use one as a motor for pumping. What H.P. shall I require to drive dynamo, and what H.P. shall I get on motor shaft?—Fitter.

[97529.]—**Enamelling.**—Will any reader inform me how to make enamelling oven to hold two or three bicycle frames, heated with paraffin oil, kind of sheet-iron to be used, and dimensions?—J. O'G.

[97530.]—**Acetate of Copper Solution.**—Will Mr. Bonney or any of "ours" kindly inform me how to make up an acetate solution of copper for electro-plating iron and steel? The solution I use at present is hardly satisfactory, being thin and bad colour.—W. K.

[97531.]—**To Mr. Avery.**—Will you kindly tell me the quantity and sizes of wire to put on a dynamo of your Avery-Lahmeyer design, as described in December *Model Engineer*, built same sizes as actual drawings? Will it not be necessary for so small a machine to alter design of armature? What will be probable output as a dynamo, and speed to run at? What H.P. as a motor?—C. H. W. Eccles.

[97532.]—**To Mr. Bottone.**—I have an undertype motor, with F.M. 2¾in. high, with cores ⅝in. by ⅞in. by ⅞in., wound with 16yds. of No. 22 B.W.G. Armature space 1¼in. diam. The present armature is a Siemens H-type, 1¼in. long, 1¼in. diam., wound with 4yds. No. 22. Can you advise me how to make this efficient, both as a self-starting motor and as a dynamo? Please state probable output of dynamo, and speed to run same. Also, current required as a motor. Full particulars of another armature would greatly oblige.—Pietre.

[97533.]—**Governor for Water-Motor.**—Can any reader kindly tell me how to make a governor for a water-motor with a wheel 4in. diameter? What H.P. will this motor give with the Manchester town's water, using a ⅛in. nozzle?—P.

[97534.]—**Turning Vulcanite.**—Please inform me the best way of turning vulcanite and ebonite, as I find that the ordinary turning tools will not stand? Any hints on polishing same will oblige.—Vulcanite.

[97535.]—**Ear Apparatus.**—Can anyone inform me if they have ever come across an apparatus for prevention of water entering the ears when bathing? Cotton-wool is apt to come out when swimming for any length of time.—Sidestroke.

[97536.]—**Lacquering Bedstead.**—I have a brass bedstead, the top rail and knobs of which are worn. Would it be possible for me to relacquer? If so, how should I set about it?—W. A. H.

[97537.]—**Induction Coil.**—To Mr. Bottone.—I am making a 4in. coil according to the instructions in your book "Radiography," with the change in the gauge of wire you were good enough to suggest some time ago. I find, however, that the vulcanised fibre circlets have warped, and I have been unable to flatten them, so I have made some discs consisting of five thicknesses of paraffined cardboard, the total thickness being $^3/_{16}$in. Would you be good enough to tell me if these will make an effective substitute?—A. H.

[97538.]—**Haidinger's Brushes.**—Will some reader who has had practical experience tell me how to see "Haidinger's Brushes"?—E. H. R.

[97539.]—**Wood Connecting-rods.**—Why are the Yankees so fond of fitting these on all their machinery? My experience is that they soon split, generally at a most inconvenient time.—A. F. Shakespear, Bromley, Kent.

[97540.]—**Quick-drying Black Paint.**—Will any subscriber to the English Mechanic give me a recipe for making a quick-drying black paint that will cover over white lead and other paints, so that it can be lettered upon with white lead in a few minutes afterwards?—A Constant Reader.

[97541.]—**Planing Machine.**—To "J. H."—Having had one example of a table that was too light, and that buckled when bolting down work on it, I should feel obliged if you would tell me if a table 3ft. 6in. long overall by 1ft. 6in. wide would be stiff enough if made ⅜in. thick. There would be five ⊥-slots down it about 1in. deep. I don't want to get it too heavy, as the beams are only 3in. wide, and the oil might get squeezed out when heavy jobs were put on the table. Also, should I gain anything by using double skew teeth in the rack, wheel, and pinion, the rest of the gear having ordinary teeth? I want to get a very smooth cut.—A. F. Shakespear, Bromley, Kent.

[97542.]—**Marble.**—I have been told that monumental masons save all chips and waste marble, which they use for making an artificial stone by mixing with some other substance. Can any correspondent say if this is so? And if so, what is the process?—T. W. Kenny.

[97543.]—**Indicated Horse-Power and Probable Brake Horse-Power of Compound Engines.**—Can anyone give this? Large cylinder 18in. diam., small cylinder 12in. diam., length of stroke 18in., revolutions per min. 190, cut-off at half-stroke, boiler pressure per square inch = 120lb.—Anxious.

[97544.]—**Welding Compound.**—Will some reader kindly tell me the best compound for welding cast steel? Also the best method of tempering cast-steel chisels for cutting iron, &c.?—Young Mechanic.

[97545.]—**Blowpipe.**—I should be very much obliged if one of "ours" would give me a few of the sizes for a 1in. gas-brazing blowpipe—namely, the size of gas-pipe, size of gas-nozzle, distance of nozzle from blowpipe mouth, and also size of bellows to work same?—Jeff.

[97546.]—**Transformer.**—Would Mr. Bottone or Mr. Avery give me the windings, length of core, size, &c., of a small transformer to be used with a scissors arc lamp? The primary current is to be 100 volts and 3 amps., alternating, which I want to transform into 30 volts and 8 to 10 amps. Also, could this transformer be made like an induction coil, and could it be used for direct current with the aid of a contact-breaker? What would the minimum cost of wire for winding be?—Arc Lamp.

[97547.]—**Induction Coil for Motor.**—To Mr. Bottone.—I have made an induction coil for motor tricycle, but it does not seem quite right. I shall be obliged if you will tell me how to improve it. Core is a bundle of No. 22 iron wire, 7in. long, ⅞in. diameter, properly annealed, and wound with four layers 24 silk-covered wire for primary. Secondary is ¾lb. 36, wound on a brown-paper tube $^1/_{16}$in. thick, in 14 layers, thoroughly paraffined and separated by three thicknesses paraffined paper between each layer. ½in. spark only obtainable with condenser of 50 sheets tinfoil 4in. by 6in. Ought not this to give ¾in. spark at least? The last layer of secondary is nearly 1in. away from core. Is this too far to be of any use, or could I expect a longer spark by putting on more wire? I use four Le Carbone dry cells, giving 1½ volt per cell. The contact-breaker works too weakly. I made the primary to slide out, so took off each a layer of wire. I tried it again, and now I get nearly ¾in. spark with only one layer on, and the contact-breaker works much stronger. This would probably do, but I am afraid the battery will run down much quicker, as there is not so much resistance in one layer of wire. Is this so? The battery is all right, as I have an ignition coil which gives a splendid ¾in. spark with it, and the contact-breaker works very much quicker and stronger, although the core is only ⅝in. diameter. The springs are about equal in strength, and adjusted about the same. I see you advise ¾lb. No. 24 for primary, wound in four layers of about 180 turns to each layer. How do you get it on a 1in. core with only 180 turns to the layer? I can get on easily 240 turns in 6in., and yet do not use more than 6oz. in the four layers. A little information would be acceptable to others, I believe, besides—W. A. J.

[97548.]—**Oil-Engine.**—Will some reader kindly describe the construction, with a sketch, of the most simple vaporiser for a ½H.P. oil-engine? Also, what should be the bore and stroke of the cylinder to give the above power?—H. Severn.

[97549.]—**Hardening Soft Steel.**—Will any of "ours" please tell me how to harden soft steel in whale oil, sufficiently hard. The articles are for cutting pliers. I have added to the oil resin and also prussiate of potash, and yet the required pitch of hardness is not attained. To harden in water would splay the handles, and result in water cracks, &c. What can I add to the oil which will give the desired result?—Polished Pincer.

[97550.]—**Electrical.**—While charging 4-volt accumulator with three quart bichromate cells, single fluid, how can I connect a voltmeter up to it so that I can see what my batteries are doing? Should it be connected up to it all the time it is charging? Also, how much bichromate of potash and how much sulphuric acid (oil of vitriol) is usual for one-quart single fluid battery.—JAMES GIBLING.

[97551.]—**Leather to Glass.**—Shall be obliged for cement or glue to stick wash-leather to glass in pieces about 2in. square. It must not be very expensive, as many pieces are required, and must not injure the leather.—R. S. T.

[97552.]—**Bricquetts.**—I shall be much obliged by an outline of the process of making coal bricquetts. Is a machine for forming them necessary, and which is the best? What substance is generally added to make them plastic, and increase burning? Any further particulars will oblige.—W. G.

[97553.]—**Magnetic Induction.**—Will some of our correspondents kindly explain why the armature of a dynamo revolves at the poles of the field magnets, and the secondary of an induction coil is wound in the centre part of the core?—L. W.

[97554.]—**Morse Code.**—Is there a low-priced manual of the Morse code with arbitraries and other hints useful for telegraph learners?—N. S.

[97555.]—**Tuberculosis in Cattle.**—I see it stated by a medical man that when the "Queen's herd was carefully tested, it was found that 95 per cent. were tuberculous." Is that true?—BOS.

[97556.]—**Glass.**—In a paragraph published by the *Daily Mail*, describing the hotel at which the Queen is to stay, I read that the windows are glazed with cristal de roche, which is far clearer than the ordinary plate-glass. Can any reader tell me what is "cristal de roche," that it should be clearer than ordinary plate-glass? What is "ordinary" in that connection?—M. E. V.

[97557.]—**Horses.**—How much does a horse grow in height from one year to four—I mean average? In a batch of thoroughbreds recently arrived from Australia one youngster of eighteen months is said to stand already about 17½ hands—the biggest thoroughbred ever seen for his age.—A. C.

[97558.]—**Motor Crank-shaft.**—Will the writer of the articles on "Motor Cars," or "Monty," kindly say if malleable iron or steel casting would be suitable for the crank-shaft of small motor? I want one with four cranks, which would be difficult and costly to forge. Are steel castings soft or brittle?—CHARLESWORTH.

[97559.]—**Spectroscope.**—Will some of "ours" oblige by helping a working man whose means are very limited? I have taught myself some chemistry from a few books and back numbers of this journal. My apparatus (glassware excepted) is all home made, including a balance accurate to a $^1/_{50}$ grain. I am getting on nicely with inorganic analysis. Towards completing my outfit I have just made a spectroscope, from information scattered over the "E. M." since 1886. The thing looks decent, and, as far as I can judge, works moderately well. But on this point I want some help. I have never seen a spectroscope, and am not clear if I am right. A reply in a back number to a correspondent tells him to make a scale for his instrument, so as to be able to compare spectra seen at different times with each other. I am quite fast here. I made the instrument as follows:—I bought two achromatic lenses, 1½in. in diameter, 9in. focus; prism I made of plate-glass, 1½in. high, and 1½in. across face clear, filled with bisulphide; it has equal sides. The eyepiece is a single lens, ¾in. diameter and 1in. focus, the slit has screw adjustment; diaphragm of eyepiece has a fine hair across it. The table is 12in. diameter, and has a finely-divided scale on its edge, which is swept by the view telescope. This, the collimeter, and the little table carrying the prism have all screw adjustments. With a Bunsen I can see all the lines of spectra of alkaline metals in Fowne's "Chemistry," and in bright daylight or sunlight I can see about a dozen dark lines and a score or two others very faint, and rather difficult to separate. These are mostly in the green. How can I map these out, and also how to get the instrument so I can always get the same readings? What is a good cheap book on the subject?—WORKER.

[97560.]—**Cellulose Packing.**—Is said (p. 510) to stop leaks in ships excellently, but that it "degenerates and becomes a nuisance from the sanitary point of view." Can any of "ours" tell how long it lasts before it becomes a nuisance?—G. A. HAIG.

[97561.]—**Paint and Oil for Models.**—Can anyone tell me what oil to use as lubricant, and also to put on bright parts of model engines when they have to stand for a time? I find ordinary sweet oil cakes in time, and has to be scraped off. Also, what black paint or varnish will do for the cylinder (steam)? Boiling water and steam must have no effect on it.—CYMRO.

[97562.]—**Water Bath.**—Why is it impossible to get the water in the inner receptacle to boil? Is it the thickness of the metal containing the water abstracts heat from the water in the outer vessel? From the above I should take it oatmeal and similar substances prepared in this manner never really boil. The correct explanation will oblige.—L. A. I. E. E.

[97563.]—**Wireless Telegraphy.**—To MR. BOTTONE.—I wish to telegraph with a Wimshurst machine over water to a moving boat about quarter-mile away. I have used a delicately suspended relay for experimenting on land, but I find it would not be suitable to use in the boat, as the least movement of the boat would cause it to oscillate, and ring the bell. Kindly say how I can make one very delicate, and yet not affected by the motion of the boat?—NO SIG.

[97564.]—**Cleaning Enamelled Slate.**—Can one of "ours" kindly tell me how to clean enamelled slate of clock which has become smeared with fingermarks?—INKY.

[97565.]—**Medical.**—I observe when I move my head sideways a crackling sound at the back of the neck; age forty-seven, abstainer, diet carefully. Can any reader kindly suggest a remedy?—F. W.

[97566.]—**Mould Making.**—I want to cast some silver medals, stamped on both sides, exactly of the same size and thickness as a half-crown, and I want to know how to make suitable moulds for making same, so as to stamp on both sides at the same time. I would also like to know the name of some reliable handbooks on mould-making.—ANXIOUS.

[97567.]—**Selenium.**—Would some reader state the process by which selenium is made to change its electrical resistance by exposure to light? I bought some selenium, which was in the shape of a lead-pencil, and kept it just below its fusing point for some hours. I then placed it, or rather melted it, between two edges of long copper plates. It did not assume the crystalline form, and exposure to light made no difference to its resistance. Kindly give explicit directions in a form which will be understood by one who is ignorant of chemistry.—THOM. CHEAM.

[97568.]—**Eclipse and Spain.**—What seaport is there on the west coast in line of totality, and what steamers touch there?—CORONA.

[97569.]—**Automatic Duplex Diaphragm.**—Will any of "ours" kindly say how thick the floating weight is of this class of fitting, and how are the vibrations from the under side of glass utilised to give increased volume of sound? The stylus is, I think, placed between the centre of floating weight and the weight-limiting screw, and not between the centre and the hinge, as is usually done.—SLIDE-RULE.

[97570.]—**Specification for 3in. Spark Coil.**—I would like Mr. Bottone's opinion of the following details for a 3in. spark coil, if likely to give good results: core, $^{15}/_{16}$in. diam., 11in. long; primary, two layers No. 14 silk-covered wire; secondary, 4½lb. No. 36 silk-covered wire; bobbin ends of ebonite, 6in. diam., ½in. thick; five ebonite discs for divisions, 5½in. diam., $^1/_{16}$in. thick. I have a tube of ebonite 10in. long, $1^1/_{16}$in. internal diam., $1^9/_{32}$in. external diam. Could I utilise this for the bobbin tube? What amount of wire should I have on each division for maximum effect, and to prevent sparking over divisions? Can anyone give hints as to the process followed for polishing ebonite?—BETA.

[97571.]—**Geometry.**—Draw a straight line through the point of intersection of two circles, so that the sum or the difference of the squares of the intercepted segments shall be given.—F. OGRAM.

[97572.]—**Telescope.**—Will any of the readers of the ENGLISH MECHANIC kindly tell me the proper diameter and focal length of the small convex mirror of a Cassegrainian telescope, the large concave speculum being 3½in. in diameter, and 22in. focal length?—W. N.

[97573.]—**Bare Patches on Animals.**—We have a cat and dog, on both of which are bare patches (not through fighting). They are otherwise in perfect health. What is the reason?—CYMRO.

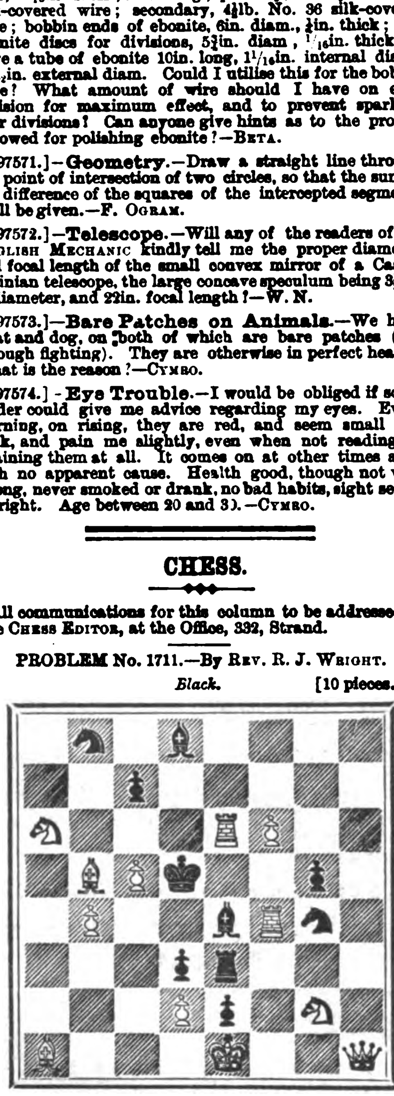
[97574.]—**Eye Trouble.**—I would be obliged if some reader could give me advice regarding my eyes. Every morning, on rising, they are red, and seem small and sunk, and pain me slightly, even when not reading or straining them at all. It comes on at other times also, with no apparent cause. Health good, though not very strong, never smoked or drank, no bad habits, sight seems all right. Age between 20 and 30.—CYMRO.

CHESS.

All communications for this column to be addressed to The CHESS EDITOR, at the Office, 332, Strand.

PROBLEM No. 1711.—By REV. R. J. WRIGHT.

Black. [10 pieces.



White. [12 pieces.

White to play and mate in two moves.

(*Solutions should reach us not later than Feb. 12.*)

NOTICES TO CORRESPONDENTS.

WHIN HURST.—Try 1710 again as reset.

T. B. CHAPMAN.—Green "Chess" (Bell and Son, York-street, Covent Garden, W.C.)

H. B. F.—List of correct solutions of No. 1710 received will be published next week.

THE Chicago Main Drainage Canal was opened on Jan. 2, by turning into it the waters of the Chicago River.

ABOUT 4,500 miles of new railroad was built in the United States last year. The average mileage for the four years from 1894 to 1897 inclusive was only about 2,000.

ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* EDITOR *of the* ENGLISH MECHANIC, 332, *Strand, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries, put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

The following are the initials, &c., of letters to hand up to Wednesday evening, Jan. 31, and unacknowledged elsewhere:—

M. B., Galway.—E. H. Micklewood.—S. Elliman.—Clytie.—A. Stamwitz.—H. A. Branley.—A. J. D.—Photo.—Secularist.—R. W. M.—Jack of All Trades.—A Fellow of the Royal Astronomical Society.—J. M.—Usage.—J. E. W.—John Holden.—Henri.—Battery.—Phono.—T. N.—C. E. L.

C. H. W.—The question about the mariner's compass has been answered, so far as is possible, in the textbooks. It is known to dip as the pole is approached; but no one knows what it actually does when carried over the magnetic pole, or the North Pole itself. (2) As to the questions about the moon, there is much literature on the subject in back volumes. (3) The idea of hollow balloons is old. The metal suggested was thin copper. We have not heard that any successful ascents were made with them.

JAMES EDWARD SCOTT.—The best way to qualify as an assayer is to study in the laboratory of an expert. A knowledge of elementary inorganic chemistry will be of great help; but much study and practice are necessary to become a competent assayer.

CHARLES.—The usual remedy is a dose of santonine, with an injection of warm salt water to wash out the lower bowel. Worm powders or tablets containing suitable doses of santonine are sold by all druggists.

GREAT WESTERN.—Inquiry at any drug stores would answer the question; but presumably lanoline could be mixed with any of the essential oils. 2. Do not know of a cure for consumption. 3. Which human voice? Say three octaves as the extreme; but depends on the individual to a great extent. 4. Living rooms, to be comfortable, should have a temperature of 60° Fahr., there or thereabouts. 5. Cows have neither incisors nor canines in the upper jaw. They have six molars in each side of both jaws, and eight incisors in the lower jaw, equal to thirty-two teeth altogether. Why not examine a head, and so answer the question in the most definite way? 6. Depends entirely on how the gas-fire is constructed. If the ventilation of the room is perfect, the purity of the air is not affected. 7. The origin of all such "duties" was the necessity to raise a revenue for the expenses of the State.

STELLA.—We do not know; but a note to Sir Edward Clarke, inclosing stamped and directed envelope, would no doubt bring a reply as to whether his book on shorthand has been published.

W. T. N.—You are quite right. On investigation, we find that our computer took the first minimum from the "Companion to the Observatory for 1900" (the calculations for which are made in the Royal Observatory itself), and calculated forward from that. It now appears that the original time given, loc. cit., was, as you point out, 12 hours too late, an error which we find has been formally acknowledged in *The Observatory* itself. We correct it elsewhere.

NO SIRRAH.—The price is evidently the difficulty. The firm mentioned did publish some years ago "The Telegraph Guide" at 1s. There were also "Popular Guide to the Telegraph Service" and "The Practical Telegraphist," by W. Lynd, respectively 2s. and 2s. 6d., published by Wyman and Sons, Gt. Queen-street, Lincoln's Inn Fields. Query inserted.

AMATEUR, J. C.—It has been frequently stated that, all things considered, the chromic acid cell is the best for electric lighting by battery. See many replies in the back volumes. The cost depends on the voltage of the lamps used, and whether the materials are purchased in large or small quantities. As you are probably going to purchase the battery and the lamp or lamps, any of the advertisers can give an approximate idea of the cost when they know the amount of light required.

A. G.—We cannot tell you. We can only insert advertisements as we receive them. Some advertisers, to save sixpence, omit addresses, or shorten them in such a fashion as to deter rather than induce replies.

E. H. MICKLEWOOD.—The index to every volume is published with the third number of its successor. If you have the numbers, you *must* have the volumes. Binding cases can be ordered through your newsagent for any volume, 1s. 6d. each.

W. J. KING.—They are tempered in the same way as other steel springs—that is, raised to a red heat, as it appears in the dark, quenched in oil, and then placed on a hot plate until the oil blazes. (2) There are works on the subject, but it depends on what information is required as to which would suit you. The booksellers near you have, no doubt, catalogues of the publishers, and can probably give you an idea of the character of the works. They are scarcely likely to be so technical as an "armourer" would need.

SUFFERER'S FRIEND.—Tar water is known technically as infusion of tar. The well-known recipe is wood tar one quart, cold water 1 gallon; stir thoroughly with a stick for a quarter of an hour or more at intervals; allow the tar to subside, strain the liquor, and keep in well-

stopped bottles. As much as a pint a day can be taken. The last question must be answered by a medical man, as it depends on the "system" of the individual. Decoction of tar is made by boiling an ounce in a pint and a half of water. Stockholm tar is the proper article.

F. C. N.—The directions specify "retort or wood carbon." "Retort" carbon is the scurf from the gasworks; "wood" carbon is simply charcoal. The ordinary carbons sold for batteries would answer all purposes. Nitric acid at 40° may mean that it contains 40 per cent. of the pure acid, or 40° on Beaumé's hydrometer. The arrangement does not seem to have come into use to any extent, and does not appear to be so convenient as the chromic-acid cell.

E. P. CLARK (New York).—The numbers required have been out of print for a long time. Current numbers will be sent to the value of the order.

AN OLD READER AND APPRECIATOR.—You should see a medical man. It may have been merely "liver," but it may have been a slight attack of syncope, following, possibly, on an attack of the prevalent influenza.

ARTHUR E. GILBERT.—Thanks; but we have given you all the space we can spare for that matter.

IN TYPE.—Slide Rule.

SPECIAL OFFER.

CHEAP VOLUMES.

In the course of the next few months we are compelled, owing to the making of the new street from Holborn to the Strand by the London County Council, to remove our Offices and Printing Works. Due notice of our removal will be given shortly. In the mean time, to reduce stock and save trouble of removal, we offer readers desirous of making up sets of back volumes *any volume* in the list below at HALF PRICE, or post free for 4s. 1d.

Any reader desirous of making a free library or working men's club a present of a few sets of volumes will find this a favourable opportunity. The offer is only available till our removal.

TERMS OF SUBSCRIPTION.

PAYABLE IN ADVANCE.

6s. 6d. for Six Months and 11s. for Twelve Months, post free to any part of the United Kingdom. For the United States, 13s., or 3dol. 25c. gold; to France or Belgium, 13s. or 16f. 50c.; to India, New Zealand, the Cape, the West Indies, Canada, Nova Scotia, Natal, or any of the Australian Colonies, 13s.

The remittance should be made by Post-Office Order. Back numbers can also be sent out by the ordinary newspaper post at the rate of 3d. each.

Vols. XXVI., XXVIII., XXX., XXXII., XXXIV., XXXIX., XL., XLI., XLII., XLIII., XLIV., XLV., XLVI., XLVIII., L., LI., LII., LIII., LIV., LV., LVI., LVII., LVIII., LIX., LX., LXI., LXII., LXIII., LXIV., LXV., LXVI., LXVII., LXVIII., also LXIX., price 4s. 1d. each Post free.

Indexes to Vol. LI., and to subsequent Vols., except Vols. LIII., LV., LVI., LVII., LIX., LXI., 3d. each, or post free 3½d. Cases for binding 1s. 6d. each.

All the other bound volumes are out of print. Subscribers would do well to order volumes as soon as possible after the conclusion of each half-yearly volume in February and August, as only a limited number are bound up, and these soon run out of print. Most of our back numbers can be had singly, price 2d. each, through any bookseller or newsagent, or 2½d. each post free from the office (except index numbers, which are 3d. each, or post free 3½d.)

ADVERTISEMENT CHARGES.

The Charge for Advertisements in the Columns headed:—

For Exchange.
For Sale.
Wanted.
Addresses.
Situations.

is Sixpence for the first Sixteen Words, and Sixpence for every succeeding Eight or part of Eight, which must be prepaid. No reduction on repeated insertions. Advertisers should state under which heading they wish their announcements to appear.

The address is included as part of the Advertisement and charged for. No displayed Advertisements can appear in above columns. Rates for Displayed Advertisements are as follows:—

For advertisements on inside pages, except page facing leader, for less than a quarter-page; per inch single column—

1	6	13	26	52 insertions
7s. 0d.	6s. 6d.	6s. 0d.	5s. 6d.	5s. 0d. each.

Per Column.—

1	6	13	26	52 insertions
£3 0s.	£2 15s.	£2 10s.	£2 5s.	£2 0s. each.

	1	6	13	26	52 insertions.	
	£ s.	£ s.	£ s.	£ s.	£ s.	
Per Page....	8 8	7 0	6 0	5 5	5 0	each.
Half-page ..	4 10	3 15	3 10	3 0	2 10	"
Quarter-page	2 10	2 5	2 0	1 15	1 10	"

Back Page, £10 10s. A few dates open during 1899.

ORDINARY ADVERTISEMENTS.

	£ s.
Thirty Words	2 6
Every Additional Eight Words	0 6

Front Page, Five Shillings for the first 40 words, afterwards 9d. per line. Displayed Advertisements, 10s. 6d. per inch. Paragraph Advertisements, One Shilling per line. No Front Page or Paragraph Advertisement inserted for less than Five Shillings.

All Advertisements must be prepaid, and in cases where the amount sent exceeds One Shilling, the Publisher would be grateful if a P.O. could be sent, and not stamps. Stamps, however (preferably halfpenny stamps), may be sent where it is inconvenient to obtain P.O.'s.

Advertisements *must* reach the Office by 1 p.m. on Wednesday to insure insertion in the following Friday's number.

For the convenience of advertisers, replies to advertisements (except those in the Exchange and Sale Columns) may be addressed to "———," care of the ENGLISH MECHANIC Office, and will be forwarded by post to the advertiser, for an extra fee of Sixpence per insertion over and above the cost of the advertisement.

All Cheques and Post-Office Orders to be made payable to THE STRAND NEWSPAPER COMPANY, LIMITED, and all communications respecting Advertisements should be distinctly addressed to:—

THE PUBLISHER,
THE "ENGLISH MECHANIC,"
332, STRAND, LONDON, W.C.

This is necessary, as there are several papers published at the same address, and unless letters are fully directed, it is impossible to tell for which paper they are intended.

NOTICE TO SUBSCRIBERS.

Home Subscribers receiving their copies direct from the Office are requested to observe that the last number of the term for which their subscription is paid will be forwarded to them in a PINK Wrapper, as an intimation that a fresh remittance is necessary if it is desired to continue their subscription.

Foreign Subscribers will have the Pink Wrapper sent ONE MONTH before expiration, in order to give them time to forward fresh remittance before subscription expires.

For Exchange.

The charge for Advertisements in this column is 6d. for the first 16 words, and 6d. every succeeding Eight, which must be prepaid.

SPECIAL NOTICE. — *Correspondents are strongly recommended not to send money or goods to strangers. The safest way when dealing with unknown advertisers is to send a Post Office Order made payable —— days after date, when in case of non-arrival of goods, or dissatisfaction, payment can be stopped.*

Bisschop Gas-Engine, one-man-power, in excellent working order, complete, with gas-bags and regulating valve. Wanted, Shaping Attachment for 5½in. lathe, or small planer.—HUMFREY, Winnington-park, Northwich.

Edison Phonograph, complete, £5. Wanted, Office Desk with drawers.—WALKER, TURNER, 75, Prince George-road, London.

Exchange, for b.g. Lathe, up-to-date **Gent's Cycle**, value £8.—BOYNTON, 11, Magdala-road, Holloway.

"**English Mechanic.**" Vols. XVII. to XXI., XXIII., XXV. to XXIX., XXXIII. to XXXVII., LVI. to LXI. Exchange Screw-plates, Tools, anything useful in workshop, or sell cheap.—THOS. PARKER, Penshurst, Kent.

Pneumatic Safety, good condition, will exchange to value £4.—P., 2, Homeleigh, Mayville-road, Leytonstone.

Portrait Lens, good as new, 18s., approval; will exchange for Banjo.—HUGGINS, 6, Swinburne-street, Derby.

For Sale.

The charge for Advertisements in this column is 6d. for the first 16 words, and 6d. every succeeding Eight, which must be prepaid.

New Illustrated Price List of Screws, Bolts, and NUTS for model work, drawn to actual size, sent on receipt of stamp. —MORRIS COHEN, 132, Kirkgate, Leeds.

Watch and Clock Tools and Materials. Catalogue, over 1,000 Illustrations, post free, 6d.—MORRIS COHEN, 132, Kirkgate, Leeds.

Wheel-cutting and Dividing in Brass or Iron to 12in. diameter.—CLEGG, Belinda-street, Hunslet, Leeds.

Amateur Astronomers.—"Hints on Refractors and Reflectors," by W. Thornthwaite, F.R.A.S., invaluable, 1s., post free 1s. 2d.—Below.

Handy Map of the Moon, by Mellor, F.R.A.S., 2s.; post free 2s. 6d.—HORNE and THORNTHWAITE, 416, Strand, London.

Lathes and Machined Parts, Wheels, Chucks, Fans, Angle-plates. Illustrated list, 2d.—JARRATT, Queen-street, Leicester.

Rubber Outer Covers, 8s. 6d. Prepared Canvas, 90 by 9, 1s. 3d.; rubber solution, best quality, 1lb. tins, 1s. 6d.—PEMBERTON.

Air Tubes, all sizes, best quality, 2s. 9d. each. Air tubes with Dunlop valves fixed, 3s. 9d.—PEMBERTON.

Cushion Tires, 3s., 4s., 5s. Solid Tires, 3s. All sizes stocked.—PEMBERTON.

Detachable Outer Covers (Licensed), 12s. 6d. each; all cycle accessories and cycle rubber goods stocked.—PEMBERTON and Co., 1, Cardwell-place, Blackburn.

"**Acetylene: its Characteristics, Generation, and Uses,**" with Descriptive Catalogue of "Incanto" Apparatus; just published, 3d. post free.—THORN and HODDLE, 1 Tothill-street, Westminster, S.W.

Brass Casting Made Easy by using Wells' specially prepared Moulding Loam. Brass casting a pleasure.—Below.

Sold in 5lb. canisters, 2s. 3d.; 10lb., 3s. 9d.; 20lb. 6s carriage paid, with instructions.—Below.

Plumbago Crucibles, with instructions for melting brass, sixpence each post free.—GEO. WELLS, Needham Market, Suffolk.

Mail Cart Wheels and Perambulator Furniture.—WALKER BROS., Primo Wheel Works, Sheepscar, Leeds.

50,000 Choicest **Microscopical Objects**, New and Second-hand Microscopes, Cabinets, Mounting Materials.—SUTER, 10, Highweek-road, Tottenham.

Catapult Elastic, square, 2d., 4d., 6d., 9d. yard. Capapults, 6d., 9d. Postage 1d.—MOODY BELL, Cheltenham.

Telescope, Calver's patent, best ever designed, Universal adjustment, revolving eye-end. Capt. Molesworth says:—"An ideal telescope."—Below.

Superb 18¼in. **Mirror** for photography or observing; Newtonian or compound, focus 96in.—G. CALVER, Chelmsford.

Books.—All out-of-print books speedily procured; any subject. State wants.—BAKER'S GREAT BOOKSHOP, Birmingham.

Bargain. — Magnificent model **Vertical Engine**, tubular boiler, glass gauge, whistle, double-action slide-valve cylinder; bronze stand. Exhibition model, silver-plated, high speed, and guaranteed perfect; worth £3s., accept 12s. 6d. free. Photograph 1d. —MANAGER, Hassall's Chemical Works, Stratford, E.

Rubber Outer Covers, average 16oz., Para rubber 8s. each.—FRANKLANDS.

Rubber Outer Covers, 8s. 6d. each, 96s. per dozen. —FRANKLANDS.

Cushion Tires, 3s., 4s., 5s. Solid Tires, 2s. 6d., 3s. All sizes stocked.—FRANKLANDS.

Air Tubes, best quality rubber, 2s. 9d. each. Fitted with Dunlop valve, 3s. 9d.—FRANKLANDS.

Air Tube, Para rubber. Marvellous value. Large stock to clear. Perfectly air-tight, 2s. each.; 21s. per dozen.— FRANKLANDS.

Cycle Capes, 3s. 6d., 4s. 6d., 5s. 6d. Also a few cycle Capes, guaranteed waterproof, 2s. 6d. each.—FRANKLANDS.

Detachable Outer Covers, licensed, 12s. 6d. each. —FRANKLANDS.

Saddles.—A clearing line in ladies' and gents' saddles, 3s. 6d. each, 34s. per dozen.—FRANKLANDS.

Inflators, 18in., 1s. 6d. each, 15s. dozen. — FRANKLANDS.

Bells.—Special line, double gong, usual price, 12s. dozen, will clear 5s. per dozen.—FRANKLANDS.

Prepared Canvas, 90 by 9, 1s. 3d. each, 12s. per dozen.—FRANKLANDS.

Pedal Rubbers, 6d. per set of four, 4s. 6d. per dozen sets; no rubbish.—FRANKLANDS.

Spanners, nickel, usual price, 18s. per dozen. Will clear a few dozen at 7s. 6d. per dozen.—FRANKLANDS.

Cycle Accessories and Cycle Rubber Goods. We hold the largest stock in the North.—FRANKLANDS, Astley Gate Blackburn.

Castings in Steel or Malleable Iron made from your own patterns.—DRONFIELD CASTINGS COMPANY, near Sheffield.

Improved flexible stranded **Tire Wires**, protected from rust, standard sizes, 1s. 8d. pair.—15, North Marine-road, Scarborough.

Motors.—Soft clean Castings, machined or rough, ready for immediate delivery, to drawings in "E. M."—H. COLBECK, Electric Cycle Works, Dalton-street, Hulme, Manchester.

The Britannia Co. publish monthly a Register of Gas, Steam, Hot Air, and Petroleum Engines.

Above List contains details of nearly 3,100 lots Lathes, Planers, Shapers, Drilling Machines and other tools.

Also Pumps, Lifts, Steam and Petroleum Launches, and various machinery and plant. State details of requirements.

Send 2d. Stamps for specimen copy—BRITANNIA WORKS, Colchester, or call at 100, Houndsditch, London.

Stamped Steel Boats, various sizes, with air-tight compartments, very light and handy.

When sending, send precise details, and we will quote for items not yet in our list.

Call Britannia Co., 100, Houndsditch, London. All letters to BRITANNIA WORKS, Colchester.

Above items are many of them second-hand, and offered at low prices.

Lathes, Drilling, Planing, Milling, Shaping Machines. BRITANNIA Co., Bonâ-fide Makers to the British Government.

Iron Castings, various, good working quality. Prompt execution of orders.—BRITANNIA FOUNDRY, Colchester.

Britannia Co. Heavy Department make Tools, &c., up to 20 tons. They also continue the Light Tool Department.—Write BRITANNIA WORKS, Colchester.

Britannia Co., having erected large foundry, fitted with electric light and crane, are open to supply light or heavy castings.—BRITANNIA WORKS, Colchester.

Fancy Ornamental Lathes, by Holtzappfel, Evans, and various first-class makers, and various appliances on sale. —LONDON MACHINERY AGENCY, 100, Houndsditch.

Special Tools, as designed for eminent firms, for any special work; interchangeable.—BRITANNIA, Colchester.

Optical Lantern, mixed jets. "Injector" using house gas; also gas gauge, sell.—WILLIAMS, Bishop's House, Clifton.

Watches, Clocks, Jewelry, Musical Boxes, Novelties. Dealers supplied at rockbottom trade prices for cash. Cheapest house in England. Lists on application. Gentleman's crystal face keyless nickel silver, 3s. 9d.; not less than three will be sent.—WOOLRIDGE and Co., 90, 91, Queen-street, London, E.C. Agents wanted. Mention paper.

"Xactli" four-volt **Pocket Dry Battery**, for lighting scarpins, flowers, &c., post free 3s. 4d.—Below.

"Xactli" **Dry Battery**, complete, with Electric Pin or Flower, 7s.—WRIGHT, 318, Upper-street, London, N.

Wheel and Rack Cutting in Brass, Iron, Steel, Aluminium, Bronze, Raw Hide, &c.—MOTOGEAR, below.

Gear Wheels.—Spur, Bevel, or Spiral, machine out any pitch in any metal.—MOTOGEAR, below.

Differential Gear for Motor-Vehicles, all types.— MOTOGEAR ENGINEERING Co., 78, Queen Victoria-street, London, E.C.

The English Mechanic
AND WORLD OF SCIENCE AND ART.
FRIDAY, FEBRUARY 9, 1900.

A SMALL MOTOR-CAR, AND HOW TO BUILD IT.—VI.

THE crank-chamber of our motor is designed of suitable strength for casting in aluminium or one of its many alloys, such as Wolframinium. Those of my readers who prefer it can use one of the bronzes (phosphor-aluminium, &c.) or malleable cast iron, in which case, particularly for the bronze alloys, the body could be made somewhat thinner. Fig. 18 is a side elevation (valve-gear side), Fig. 19 a plan partly in section, and Fig. 20 an end elevation showing the square facing for the cylinder to bolt against. In the upper right-hand corner of Fig. 18 is a small section showing the thickness of the bosses for the studs holding the covers on each side of crank-chamber. These bosses show dotted in the side elevation, and appear also in the plan, Fig. 19. The pattern for this portion of the engine is made solid, the interior being cored out, a suitable core-box being provided. In the upper part a hand-hole is cored out, through which access may be had to the connecting-rod big end. A facing $^1/_{16}$in. high by ½in. wide surrounds the hand-hole, whose position may be obtained from Figs. 18 and 19, being marked A in both views. The part marked B, Fig. 18, bolts against the rearmost cross-bar of the carriage-frame by means of two ⅝in. bolts. There must be a suitable allowance made for machining this facing to enable it to be fitted squarely to the framing. The boss C, Figs. 18, 19, and 20, is to receive the fulcrum-pin of the valve-gear bell-crank lever, and its position is of great importance; therefore the dimensions given should be most strictly adhered to. A small error here will result in a lot of the work being thrown out and rendered useless. To know where to allow for machining in making the patterns, a reference to the general arrangement drawings, Figs. 2 and 3, will be of service.

Having the casting, the first proceeding will be to line it out to the dimensions in Figs. 18, 19, and 20. The casting being rather large (the largest if we except the fly-wheel), I do not suppose many amateurs will be able to machine it themselves; but they can do all the marking off, which will save expense. For the benefit of those whose equipment of tools enables them to do all the work themselves, I will indicate the methods I should adopt. Having marked out and centre-punched circles and witness-circles around the 7in. openings in the sides, I should clamp the casting on a face-plate, setting it by the centre punched circles, and bore out the two sides for the reception of the covers to 7in. diameter. At the same setting the facing, which is $1^1/_{16}$in. wide, can be faced over on one side of the casting. It can now be

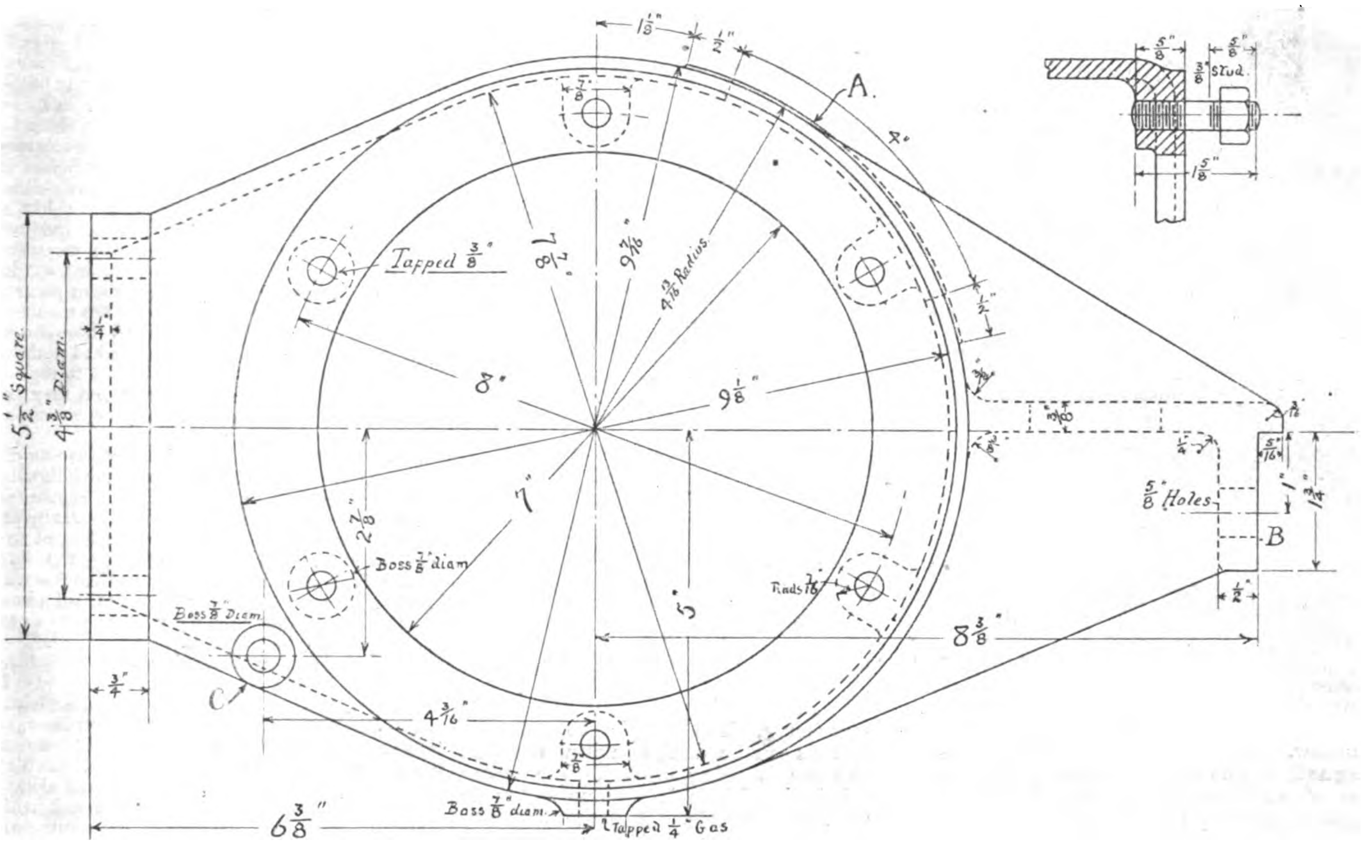


Fig. 18.

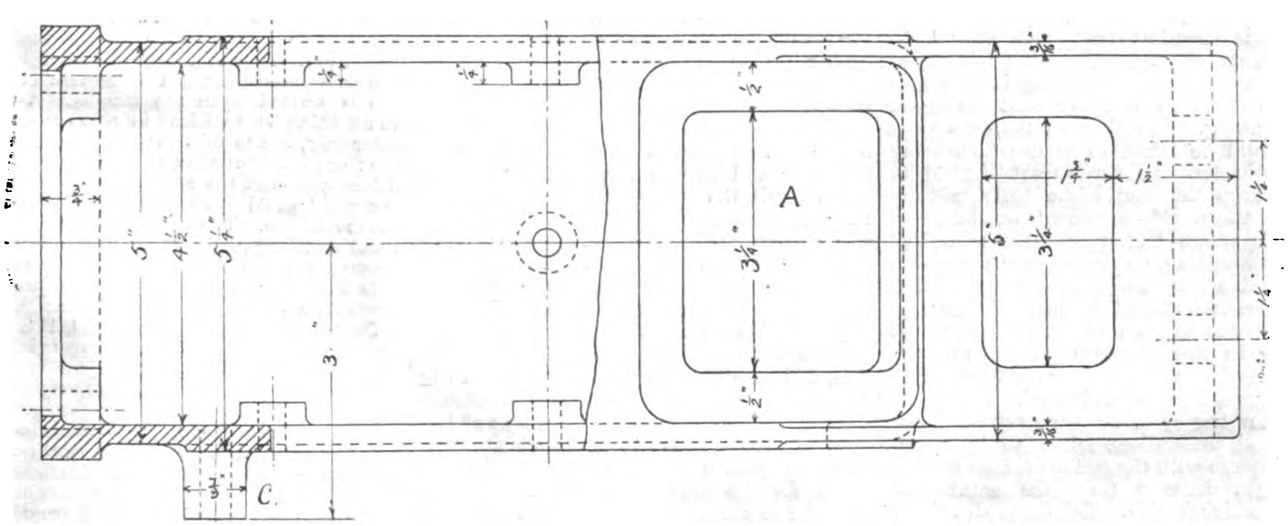

Fig. 19.

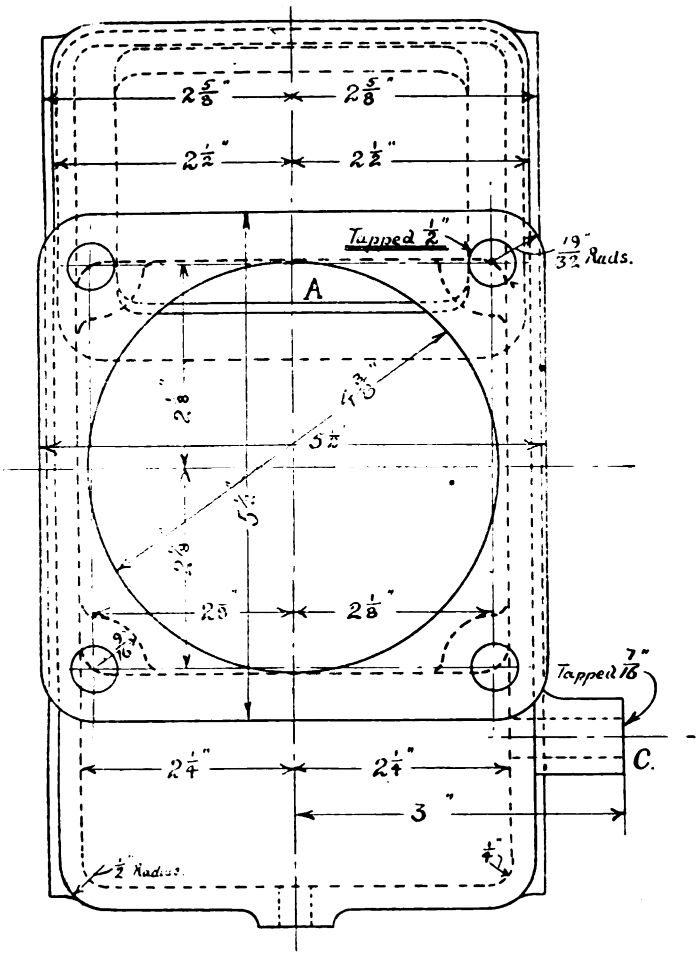

FIG. 20.

removed, and a piece of hard wood screwed to the face-plate, and turned to 7in. diameter. Its thickness is immaterial so long as it can be screwed on securely. This disc of wood serves to centre the casting, which should again be clamped to the face-plate; this time the rough facing being outermost. This is now faced over, and if the face-plate is true, both sides of the casting will be found quite parallel; and it is essential that they should be so. Otherwise, there is small chance of the crank-shaft bearings being in line with each other, which would prevent the motor from running. In facing off the sides great care should be taken to insure their being exactly the correct distance apart—i.e., 5¼in., and to keep the centre line truly midway between them. Measurements can be taken from the centre line, previously scribed all round the casting, to the edge of a straight-edge laid across the cover-facing. These measurements should be made frequently: otherwise too much may be taken off, and packing in this place is an abomination. The holes for the cover-studs will be left till the covers are turned and fitted. The square facing for the cylinder can next be shaped over, and precautions taken to insure its being square with the facings for covers, and the right distance from the crank-shaft centre, which is 6⅜in. Take note also that it must be truly at right angles to the horizontal centre lines of the engine, so that when the cylinder is in position its centre-line produced would cut the centre-line of crank-shaft. Boring out the hole into which the end of cylinder enters at first sight would appear to be difficult. One way is to clamp the casting on to the lathe saddle, the turned facings insuring its being level, with the centre of the 4⅝in. hole in line with the lathe centres, and use a tool held in a chuck to bore it out, advancing the casting by traversing the saddle along the lathe-bed. The flange B is next planed or shaped across, and it must be parallel to the cylinder facing. The two ⅝in. holes for the frame-bolts can be drilled in it now, or left till the car is being erected. The facing around the hand-hole is filed up and made as level as possible. A piece of sheet brass, aluminium, or whatever material the crank-chamber is made of, is to be bent to the radius of, and made the same shape and size as, the hand-hole facing, and secured in place with ¼in. set-screws placed one at each corner and one in the centre of each of the four sides. To prevent the oil which is splashed about the inside of the case from leaking from under the cover, a single thickness of brown paper is to be placed between the cover and the case, and all screwed up tight. Drill the boss C right through into the crank-chamber, face off the end with an arbor-cutter so that it is the correct distance from the centre of motor, and finally tap it out 7/16in. The arbor-cutter is used before tapping to avoid damaging the thread. I need hardly say that this boss must be drilled and tapped quite square with the longitudinal centre line, and parallel with the crank-shaft centre line. The boss at the bottom of crank-chamber is drilled, faced off, and tapped ¼in. gas, to take a small cock, by which waste lubricating-oil may be run off. Drilling the holes for the four studs which hold the cylinder to the crank-chamber is an operation requiring care. The cylinder and crank-chamber should be placed together on the marking-off table, in their proper relative positions, and their centre lines made to coincide so that the facing on the cylinder for the valve-box is parallel with the facing on the crank-chamber for the cover, valve-gear side. The holes can then be marked off on the crank-chamber, using those previously drilled in the cylinder flange as a guide. Drill and tap these very carefully, and screw in four ⅜in. studs tightly. Put the two parts together again, and run the nuts on moderately tight, and again test them with scribing block and square on the surface-plate, to make sure the studs have been placed correctly. If they have not, there is nothing for it but to ease the holes in the cylinder flange, though this should not be permissible on first-class work.

MILLWRIGHT'S WORK.—XXIV.

IF the new wheel is to be a bevel, even more care is necessary than for a spur, because little inaccuracies in wheels of this class, especially when the breadth of face is considerable, soon result in bad gear.

In addition to the trouble of obtaining properly formed teeth, the correctness of the bevel is important. It is very easy to get this slightly out of truth, and when that happens, bad gear is unavoidable. There is no chance to put bevel-wheels farther into or out of action as in spurs, because one end of the teeth is held in check by the other. At the small end, an inaccuracy amounting to 1/16in. will be quite sufficient in many wheels to give trouble. In narrow-faced wheels there is little to contend with; but as width increases, the greater must be the care exercised. The bevel should be both measured and checked by other measurements, and special care must be taken in preparing pattern parts to guard against error on the part of the moulder. The insisting on the necessity for all these checks may seem trivial to those who have had nothing to do with making new bevel-wheels to replace old ones, or to gear with old ones; but they are fully warranted and emphasised by experience of good and bad work.

If a new wheel is to be made to replace an old one yet at work, dimensions taken in the following manner will afford a check on one another in drawing out the wheel in the shop:—Diameters are taken at the tooth-points, on the largest and smallest ends. This can be done in the way previously described as suitable for the measurement of spur-wheels, either by strips laid across the diameter of the shaft, if the latter is so small as to offer no interference to this method of measurement; or by measuring the radius from the shaft to the tooth-points and roots. If neither of these is available, correct dimensions can be obtained by hanging two plumb-lines, as in Fig. 152, and taking measurement between them, the dimensions being obtained on both large and small diameters. The lines can always be suspended from beams or other attachments overhead, or from a strip laid over any convenient support somewhere above the wheel. Measurement at A can be taken with a strip, or small iron rod, or large wire, or with a steel tape —not so safely with a linen one.

A templet is made to the bevel of the tooth-points, Fig. 153 or Fig. 154, whichever happens to be most convenient, and the breadth of tooth-face is scribed upon the templet. A novice would think it sufficient to measure one diameter only, and to take the angle and width of face; or to measure the two diameters and width of face, and omit the angle. In either case the new wheel would almost certainly not be exactly like the old one. The reason is, that the roughnesses and inequalities in castings affect every measurement, and the consequence is that these little irregularities and discrepancies are easily averaged, when each checks the other.

The templets, shown in Figs. 153, 154, should properly be made in sets of two, one giving the angle at the points of the teeth, the other that at their roots. Of course, in properly designed wheels, these should both run to the apex of the pitch cones, and one could be easily obtained from the other, and from the total length of tooth measured at one end. But then millwrights often have to make bastard wheels to match old ones, which are not properly designed according to standard rules, and for this reason nothing must be taken on trust.

The templet in Fig. 153 is shown fitted against one face of the wheel boss, that in Fig. 154 against a parallel straight-edge, which should bridge over the width of the wheel. A large shaft coming in the way would interfere with this method, while a small one would not. Fig. 153 is of sheet iron, tin, or zinc, bent to fit round the shaft, Fig. 154, of wood.

Rubbings are taken of the teeth at the large end. As a check they may be obtained, too, at the small end. It is sometimes safe to check the bevel of the teeth of old wheels in plan view—that is, to see whether their flanks and faces point

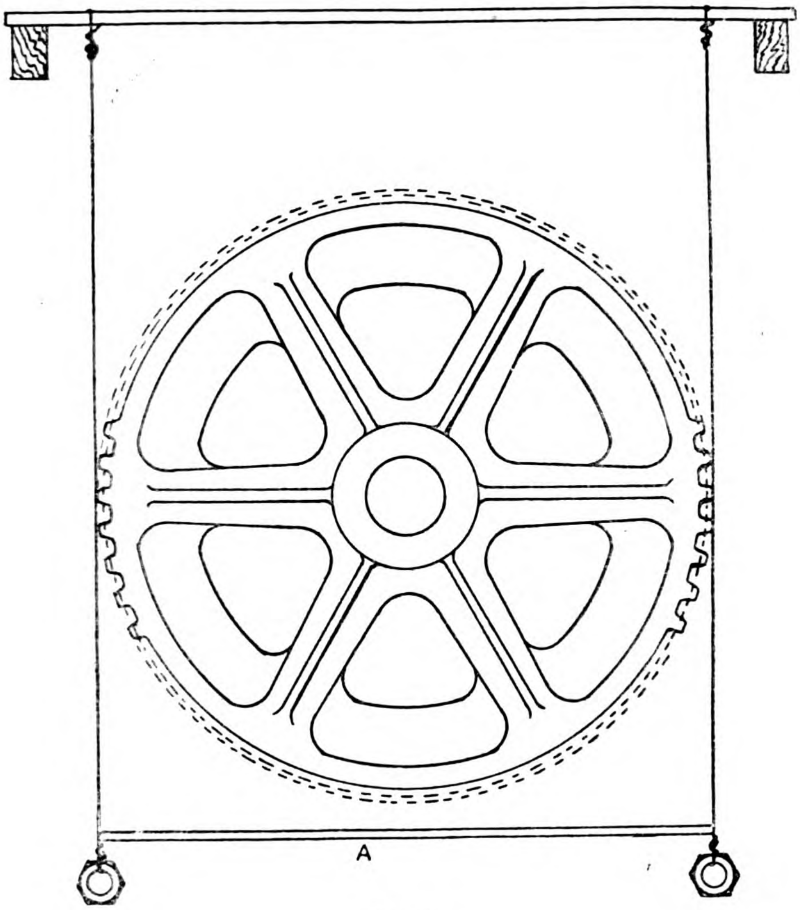

FIG. 152.

to the apex of the cones. They always ought to, but they don't. A templet like Fig. 155, fitted by planing between the teeth, will settle this point. Particulars of bore, boss, and arms follow, and are inserted in a sectional view as in

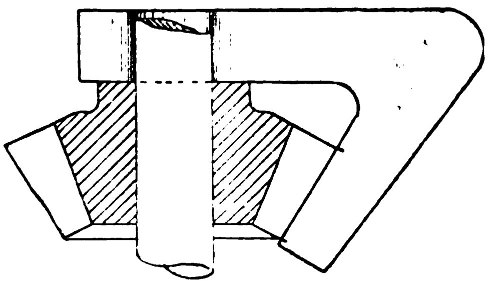

FIG. 153.

Fig. 156; width of rims, &c., being marked on a sketch giving a view as in Fig. 152.

If the bevel-wheel to be newly made has to work with an existing one, then the latter must be measured by the methods just noted in order to the correct matching of the new one to it. If the shaft for the new one is in place, measurement must be taken from that to the teeth of the

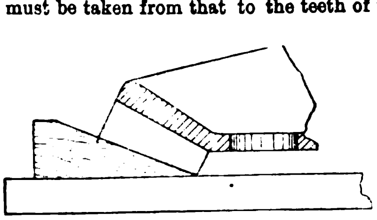

FIG. 154.

existing wheel, to get the correct radius, which must determine the number of teeth in the new one.

Being back at shop, the wheels are to be struck out to full size. The sheet with the rubbing is pinned down upon the board, and the pitch-circle located and struck. Internal and external templets are made in thin wood to the curve of the pitch-circle, and laid in turn upon it. Then generating circles are taken at random, and rolled round on the internal and external curves until a striking-point in the circumference of some

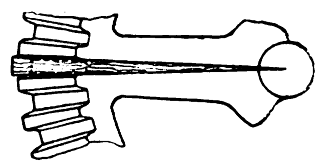

FIG. 155.

circle or circles traces the tooth curves. Then those are the circles with which the curves of the teeth of the new wheel will be struck. Very probably there will be found to be a difference in the diameters of the circles, which suit the flanks

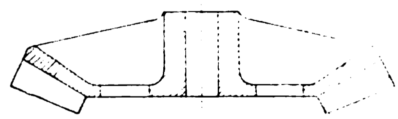

FIG. 156.

and faces respectively. Then the circle which suits the flanks of the old wheel must strike the faces of the new one, and the circle which strikes the faces of the old wheel must strike the flanks of the new one. To apply the circles to the new

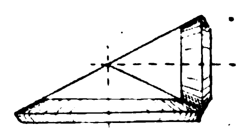

FIG. 157.

wheel, sweeped templets, inside and outside, must be cut to the pitch-curve of the new wheel, and the circles rolled upon these.

So far, the method is identical with that for obtaining the curves of the teeth of spur wheels. But in the case of a bevel wheel the shapes of the teeth will be laid down, with circles on the major diameter only. Having obtained them thus, they are transferred to the minor diameter by drawing lines representing widths and striking centres to the common centre of the two wheels.

Bastard bevel wheels have to be fitted sometimes

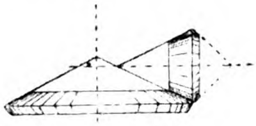

FIG. 158.

to existing ones. Fig. 157 illustrates correctly-formed wheels, correct because the pitch planes of both run to a common apex. Figs. 158, 159 illustrate bastard wheels, so-called because their pitch planes do not meet in a common apex. Such a departure from correct form is necessary when a new wheel has to be fitted to an existing one, but in which the relative velocities will not permit of the right number of teeth and right diameter being used, or in which the original wheel is found to be incorrect. The teeth may be less or greater in number, causing the apex of the new

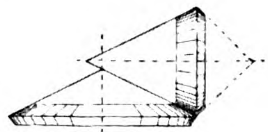

FIG. 159.

wheel to fall short of, or to run beyond that of the existing one. Such wheels, though incorrect in principle, run well if their angles and their tooth shapes are made properly.

To set them out, strike the pitch cones suitably to the number of teeth. Take a templet of the teeth of the old wheel, and find the circles by which its curves were generated. Then strike the teeth of the new wheel to suit, projecting the pitch diameters, in the manner shown, by the method which is well understood. **J. H.**

ORNAMENTAL TURNING.—XXXV.

By J. H. EVANS.

PROCEEDING with our considerations of the various apparatus connected with ornamental turning, we now approach a very important addition — viz., the spiral apparatus. I have heard it argued that all screws are spiral: consequently all spirals can be no other than screws, in the strict sense of the term; but it will be readily understood that, beyond certain pitches or twists, the word "spiral" or "helix" is more applicable, especially for the purposes of ornamental turning and decoration. It is not my intention to deal now with screw-cutting, only as applied to our particular purpose; at the same time the relation between the movements of the mandrel and guide-screw are practically the same—both in the screw-cutting lathe and the spiral apparatus we are now about to consider.

In the case of the former (the slide or traversing lathe), the revolutions of the mandrel are connected with, and derived from, a train of wheels which gear to a similar wheel attached to the main screw of the lathe, which engages with the sliding saddle, and so carries it along the bed of the lathe. Now, as I have already stated, the principle of the apparatus we are now about to deal with is identical, the revolution of the mandrel being conducted by means of a set of change-wheels, which connect to a wheel on the main screw of the ornamental turning slide-rest. This, it will be at once evident, is in every way more suitable to our present purpose, and meets all the conditions likely to be required in the production of ornamental spirals; and many other adaptations we shall find necessary as we proceed. There are two ways of attaching the spiral apparatus to the lathe—either at the front or back of the mandrel frame. This being the case, it will be necessary to go fully into each, so that whichever is deemed the most suitable may be adopted. Again, it may transpire that the lathe

to which it is to be fitted will not have a traversing mandrel; if this is so, there is nothing for it but to have it in the front.

Having thus decided this point, the first thing to do will be to cut out a circular groove in the front of the headstock. I have shown this in Fig. 1, on which also I have illustrated the radial arm in dotted lines, as fixed on the mandrel frame. The circular slot should be about 2in. in diameter, and $\frac{3}{16}$in. wide. The exact dimensions, however, to which it is made, must be governed by the shape and size of the mandrel frame to which it is to be fitted. It must be cut concentric to the mandrel (vide A, Fig. 1) in order that it may partially rotate to suit the requirements of the various trains of wheels which from time to time are to be employed. At the lower extremity of the arm a curved slot B is made, and through this passes a screw into the hole C, which is tapped into the mandrel frame. It is this screw which fixes the arm securely, when the necessary position to sink the train of wheels in use is obtained.

An elongated slot, or mortise 7½in. long, as seen at A, Fig. 2, is made in a line with the axis of the circular fitting A, Fig. 1, and it will be at once seen that although the semicircular slot B is of no considerable length, the amount of elevation and depression of the arm is sufficient for all purposes.

In order to facilitate the manipulations of the fixing screw, a curved spanner, as shown in Fig. 3, is the most suitable. The screw should be made

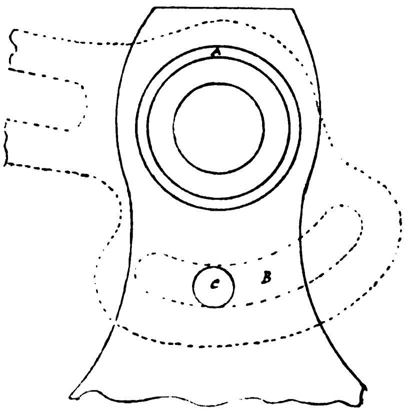

Fig. 1.

one inch across the flats, and for further convenience a hole is drilled in each, so that when required, a tommy, at the opposite extremity of Fig. 3, may be employed.

The mortise A, Fig. 2, must be carefully set out and accurately filed to fit a gauge, which must be made; the usual width being ⅝in. It must be parallel from end to end, also square to the face. The object of this aperture is to receive the fitting attached to the bodies of the arbors, which, when fitted, move throughout its length, and are fixed in the position found to be that which will accommodate the various trains of wheels. In Fig. 2 the radial arm is shown in full with dimension marked. Reference to this engraving will more fully bear out the remarks concerning the same as applied to it in Fig. 1.

We will now proceed to the making of the arbors. Of these there are three—viz., the single, double, and intermediate arbor; the latter being essential to the reversing of twists or spirals from right to left. First let us take the metal body. This is illustrated by Figs. 4 and 5. It is, in the first place, cast in circular form. It is then held in a jaw chuck and bored out at the centre A (Fig. 4). This hole should be slightly taper, as it is for the purpose of receiving the steel spindle A (Fig. 7). The external diameter is then turned all over from this fitting, it being placed on a steel mandrel for the purpose. The next thing to do will be to cut the screw B (Fig. 4). This should be a rather fine thread, but although preferable, it is not actually imperative. Proceeding, we come to the tubular nut (Fig. 6). This must be turned and screwed to fit B (Fig. 4), as it is to be employed to hold it securely to the radial arm when in use. We may now file away the two sides to pass into the mortise slot of the arm. This is seen in A (Fig. 5), and it must be accurately fitted to slide throughout the length of the slot. The nut (Fig. 6) is turned to a cylinder externally, the extremity being filed to a hexagon

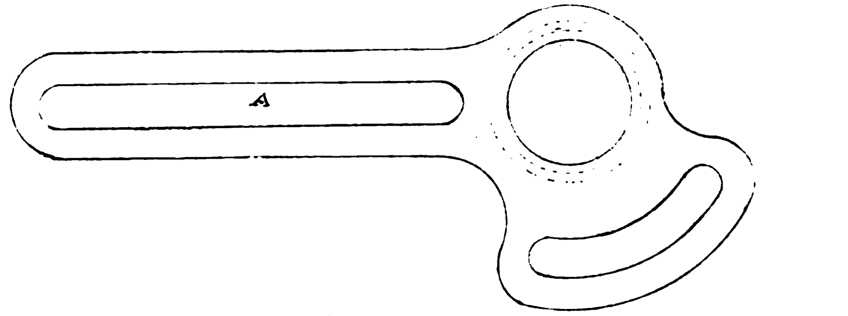

Fig. 2.

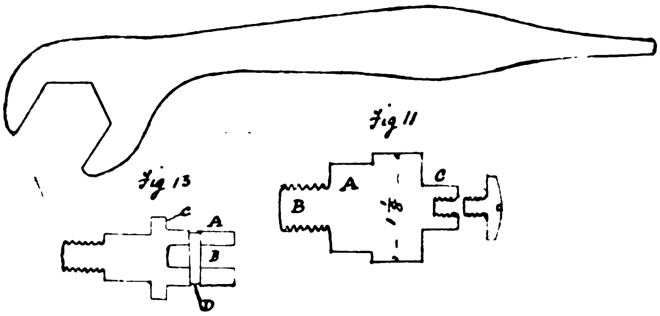
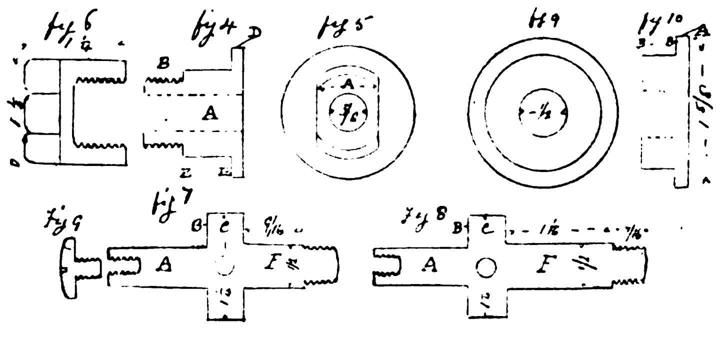
one inch across the flats. It is, of course, necessary to make two of each of these—one for the single and one for the double arbor. Further illustration will, however, be quite unnecessary, as they are identical.

We come now to the steel spindles which revolve within the parts just so far finished. Figs. 7 and 8 give a clear view of these in all parts. They are each accurately fitted at A to revolve in the aperture A (Fig. 4), and retained in position by a screw fitting in the end at B (Figs. 7 and 8)—a screw with head extending beyond the diameter of the fitting, as shown in Fig. 9, in order that it may form an opposite bearing to the face of the collar on spindle, B B, Figs. 7 and 8. The end of the spindle must be in exact accord with

Fig. 3.



that of the face B (Fig. 4), and when the screw is in its place, and the fitting finished, there should not be any movement between the two, but a smooth revolution must be the result. The width of the collars C on Figs. 7 and 8 is about $\frac{3}{16}$in. I say "about" in this case, because the precision must be determined by the dimensions of other parts when fitted. Fig. 4 at D is ¼in. wide, and from E to E the width must be just under that of the thickness of the radial arm. The collar of Figs. 7 and 8 have four holes drilled through each for the purpose of holding them firmly, while the wheels are tightened on to the fitting. This it will be at once recognised as necessary, as there



is no other means of resisting the force required to be exerted by the spanner on the hexagon nut at the end.

I have in this case shown both spindles, as they differ in their actual length at that part, F F, 7 and 8, the former being the single arbor, the latter the double one, the meaning of the term as applied being, on the one, a single wheel only is employed, and on the other, two are placed—that is, a wheel and pinion, the latter being one of those of smaller diameter, and having a hole of ¼in. diameter, and its width the same.

The larger wheels are bored out to 1¼ diameter, and the width when finished is ⅜. The increase in the size of the aperture necessitates the employment of an auxiliary boss or filling piece; this is made as shown by Figs. 9 and 10. A gunmetal casting must be used, and when bored at the centre to ¼in. to fit E F, Fig. 7 and 8, it is placed on a mandrel, and the exterior turned to fit the apertures on the wheel, the total width of fitting and collar, A, Fig. 10, being half, the same as the pinions. These dimensions are necessary to be studied, as any error will affect the trains of wheels running in the same plane, and if this should occur it will cause much trouble and inconvenience. The fitting B B, Fig. 10, must be just under the thickness of the wheel, so that the washer which covers the space of the aperture may take full effect when all is tightened for use, the collar A making up the width to the required dimension.

Continuing, we now come to the intermediate or reversing arbor. This is made entirely of steel. Reference to Fig. 11 will show clearly the shape and manner in which it is made—in the first place of circular form. It is then filed at A to fit, and slid in the radial arm in the same way as those we have just considered, the screw B extending as seen on the one side is provided with a hexagon nut to fit the spanner, Fig. 3, having before it a thin steel washer. On the front extension C a wheel of 30 teeth is fitted to revolve thereon, the front being countersunk to receive a screw, the head of which must be made sufficiently large to form a bearing, by which the wheel is kept in contact with the face of the collar.

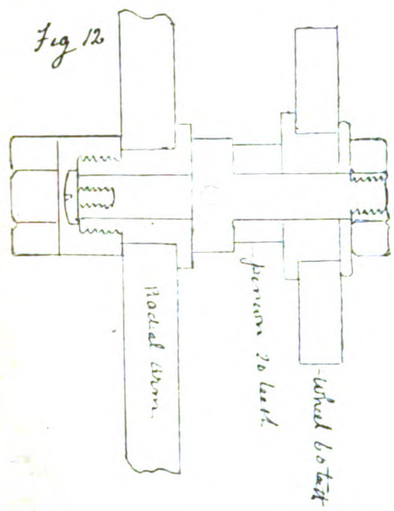
This wheel is simply an idle wheel, or one of communication, used for the purpose of reversing the direction of the spiral, which has been previously cut without its intervention. An important point to study, when fitting up the arbors, is to take care that the diameters of the various parts do not prevent the 30-wheel on the intermediate one being placed in gear with the small pinion. Should it be found that a reduction in any part is required, it may be done by filing a

flat on the intermediate arbor to allow it to pass further along the arm, free of the projection on the double arbor, which carries the wheel and pinion.

It may occur to some of my readers, especially those quite uninitiated in this particular apparatus, to wonder why the larger wheels are bored out to an increased size. It will be seen that many of them have to be employed upon the dividing chuck, which, having to attach to the mandrel nose, must of necessity be left of sufficient substance for strength: hence the increase in the aperture of the wheels which fit over the chuck, and are there fixed, thus forming the connection between the screw of the slide-rest and the mandrel. Being possessed of the filling piece, Fig. 10, we are enabled to employ all the wheels upon either of the arbors or slide-rest screw.

I have shown in Fig. 12 the double arbor as fixed to the radial arm, having both a wheel and pinion attached. This being in sections fully explains the other detailed parts, and will, I hope, be of considerable service in the construction of these parts.

We have still to provide a means of attaching the wheels to the main screw of the slide-rest, and this is done in the following way:—In Fig. 13 will be seen the illustration of a steel rocket, which is fitted in at A into a hole bored to receive it in the left end of the slide-rest, that is, of course, opposite the winch-handle. The best way to insure perfect truth is to make a pin-bit, he pin of which must accurately fit the hole already there, which receives the end of the main



screw. The socket must then be bored at B to fit over the end of the screw, when the face of the socket C bears against the end of the slide-rest. When these fittings are made, a hole must be bored through the slide from top to bottom, in order that the pin D, by which the socket is held to the screw, may be inserted and withdrawn. It will be seen, by reference to the engraving, that the pin D is made of less length than the diameter of the fitting. This is for the convenience of insertion, as it is a difficult job to get it so exactly in position that it will not interfere with the smooth rotation of the screw and socket when in action. Moreover, although it is seldom removed when once placed, it sometimes has to be; and each time the pin is reinserted it may go slightly beyond its previous position; therefore it is better to shorten it off as seen. The opposite extremity of the socket is made to fit the wheels of smaller size—viz., ½in., a second filling piece being employed when it is required to use a wheel with large aperture; the extreme end is provided with a hexagon nut of the same size as those belonging to the arbors. Formerly the nut used for this socket was made of circular form, with a series of holes drilled in the face, and a double-pin wrench made to fit the same. This I found inconvenient, and as the hexagon nut is more readily manipulated and less trouble to make, I have discarded the circular one in favour of it.

With the foregoing details I do not think much trouble will be experienced by any amateur of mechanical ability in the manufacture of it. It is practically straightforward work, and with care there need be no failure. I may mention that it will be as well when preparing the pattern to make those for the wheels. It is always an advantage to have the whole of the castings for such work done at the same time: it insures uniformity of colour and texture. Having said so much, I had better now give the dimensions required for the full set, also the number of teeth in each, which are as follows:—

No. of teeth—

144 120 96 72 60 60 53 50 48 36 30 24 20 18 16 15

Diameter in inches—

$7\frac{1}{4}$ $6\frac{1}{8}$ 5 $3\frac{3}{4}$ $3\frac{1}{8}$ $3\frac{1}{8}$ $2\frac{3}{4}$ $2\frac{5}{8}$ $2\frac{1}{2}$ $1\frac{7}{8}$ $1\frac{5}{8}$ $1\text{-}\frac{5}{16}$ $1\frac{1}{8}$ 1 $\frac{15}{16}$ $\frac{7}{8}$

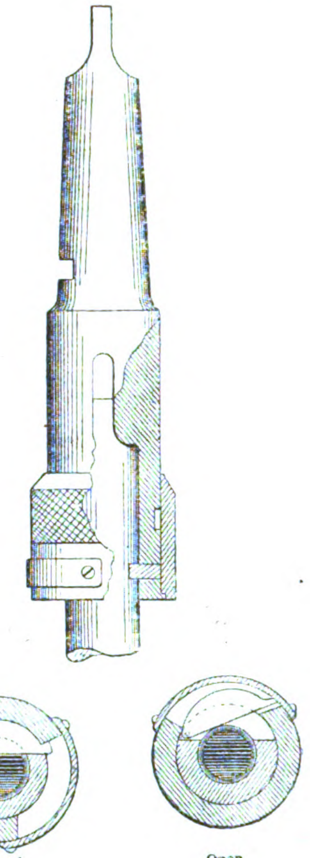
I should strongly advise those who desire to make this apparatus to turn the wheels, and send them to a wheel-cutter to be cut. My next will treat with the dividing chuck, &c.

WIRELESS TELEGRAPHY.

THE promised discourse on wireless telegraphy was delivered at the Royal Institution last Friday by Sig. G. Marconi, M.I.E.E. After describing the principal features of the invention, he referred to its practical uses, and stated that the experiments between the South Foreland and the Goodwin Sands Lightship had demonstrated that wireless telegraphy was trustworthy and certain in operation. He expressed the hope that before long the necessary funds would be found to enable Trinity House to establish communication all round the coast with lightships and lighthouses, by means of which a vast amount of property and many lives might be saved. When coming back from America he established an installation on the *St. Paul*, and by that means all the important news relating to the war was transmitted a distance of about 66 miles, while the vessel was steaming 20 knots an hour. The news thus collected was printed aboard in a paper called the *Transatlantic Times* several hours before the arrival of the steamer at Southampton. This rather pointed to the probability of voyagers being able to keep up communication by means of wireless telegraphy with the land they were leaving or going to. At the tardy request of the War Office he sent out one of his assistants, Mr. Bullock, and five others to South Africa. It was the intention of the War Office that wireless telegraphy should only be used at the base and on the railways; but officers on the spot realised that it could only be of any practical use at the front. Accordingly the assistants volunteered to go to the front, and on December 11 got up to the camp at De Aar; but when they arrived there they found that no arrangement had been made for the supply of poles, which were essentially part of the apparatus on which to erect the screens, and had to be obtained on the spot. To get over the difficulty they manufactured some kites, and in that had the hearty assistance of Major Baden-Powell, a relative of the gallant defender of Mafeking, and Capt. Kennedy. The results obtained were not altogether satisfactory, for the variability of the wind often rendered the kites useless for the purpose. The partial failure was due to the lack of proper preparation on the part of the military authorities, and had no real bearing on the practical utility of the system when carried out under normal conditions. It was reported that the difficulty of getting through from one station to the other was due to the iron in the hills. If it had not been telegraphed from South Africa it would hardly be credible that anyone should commit himself to such a statement. [It is probable that some error was made in confusing wireless telegraphy with the difficulty in making compass surveys.] As a matter of fact, iron would have no more effect than any other metal on the "waves," and signals have been sent across New York, where the tall houses have steel frames. During the naval manœuvres signals by means of wireless telegraphy went through a fleet of thirty ironclads and the apparatus was not affected thereby. However, on getting the kites up, communication was easily established between De Aar and the Orange River over a distance of 70 miles. Poles had now been obtained, and although not quite high enough for conveying messages long distances, yet they were sufficiently high to be useful. Stations were now established at Modder River, Belmont, Orange River, and De Aar, and had worked well, and would be invaluable in case the field-lines should be cut by the enemy. It was also satisfactory to know that the military authorities had arranged to supply small balloons to his assistants for portable installations on service wagons. While he admired the determination of his assistants to do the best they could with the most imperfect local means, if he had been on the spot he should have refused to open the station until the officers had found means to obtain poles for elevating the wires which were necessary for success. In concluding his discourse, Sig. Marconi expressed the opinion that by means of wireless telegrams would soon become as common on the sea, and as much in daily use, as they are upon land. It was stated that the War Department is now sending out a number of small balloons for taking up the "screens," and these, being portable and practically independent of the wind, will probably be found of great utility.

A NEW DRILL-SOCKET.

THE newest thing in the way of a drill-socket, designed to prevent twisting off the tangs, is shown by the accompanying engraving. The new feature consists of cutting a rectangular notch across the taper shank, as shown, into which a hinged steel plate is locked by rotating upon the collet a collar, the construction of which is shown very clearly by the engravings, and which, when in one position, allows the plate to swing outwards and free the drill, and when rotated to another position, forces the plate into engagement. It is stated that



Closed Open

this device has been used sufficiently to show that it is practical, and that it prevents broken drill-shanks. It is made by J. L. Cook, Springfield, Ill.—*American Machinist*.

ANIMALS IN KHAKI.

THOSE who doubt the rationale of khaki as prescribed for the gentlemen ordered South, should pay a visit to the Natural History Museum in Cromwell-road, says Mr. F. G. Aflalo in the *Morning Leader*. Inside and out the building is a study in the fashionable colour, and even the presiding statue of Darwin wants only a few weeks of neglect to blend in ghostly fashion with the khaki tiles behind. It may be objected that these are not true khaki colour, and indeed the objection has some weight. But it must be remembered that several shades have lately been included in the term, and some of the wools in which charitable ladies have knitted socks and caps for the absent troops bear little resemblance in colour to the peculiar Indian material associated with the name. In order to guard against confusion on a recent quest of khaki animals, I furnished myself with a khaki belt that of yore encircled my slender waist on Afric's plains. For—I confess it—my eye for colour resembles the ear for music of the man who knew only one tune, the one that was not "God save the Queen!"

Given a little latitude in shade, however, it is amazing how many of earth's creatures are clad in khaki or in some useful tint closely approaching it. The very first case in the museum entrance hall, the remains of the giant sloth, is full of khaki, and on the same floor is a still more striking group from the Egyptian desert, khaki jerboas and birds and reptiles hiding against a background in harmony. Look, again, at the stony soil in a beautiful case of cream-coloured coursers in one of the bird galleries,

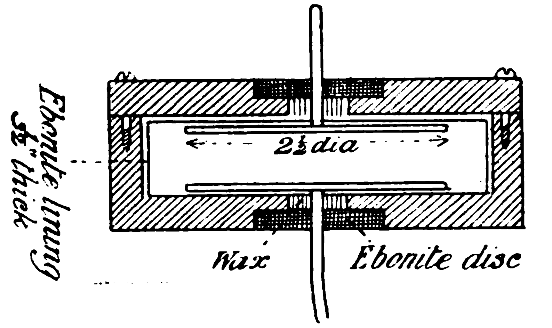


FIG. 1.

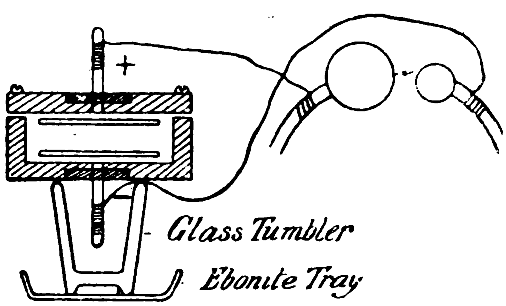

FIG. 2.

or, in another, at a fragment of sand-pit peopled with martins.

The colour protection achieved by khaki comes midway between the melanism and albinism so strikingly figured in that same entrance hall; and, ascending the great stairway, the visitor, turning to the left and resisting the seductions of the Gould humming birds, finds himself in an avenue of South African gentlemen in khaki, antelopes of every size, the gemsbuck, beisa, lichi, and—most striking of all—the puku and hartebeest. These timid and defenceless creatures, that must often trust wholly to colour protection when swift flight would but attract notice, are in khaki uniform from head to foot, but there are shades of the prevailing colour on the lions, river hogs, wild asses, and giraffes; there are khaki seals and sea-lions, khaki monkeys and otters and foxes, hunting dogs and wolves and hyænas.

Against the sandy soil of Natal the protection of khaki raiment is invaluable. Nature knew this before the War Office, as witness some of the local spiders and centipedes and grasshoppers, or the moths and butterflies. Every continent has its gentlemen in khaki; Australia its kangaroos and thylacines, North America its wapiti, South America its guanaco, Asia its camel, swamp deer, and markhore. Even the British gallery gives us, among prudent sand-dwellers, hares and rabbits and adders.

Search below the waters of the seas, and we shall find the upper surface of many flat fishes that pass their time on a background of khaki sand, uniformly khaki, in some variegated with red spots. Some of the mountain dwellers, whose homes are white with winter snows, themselves assume a white coat to assimilate with their altered surroundings. Of such are the stoat and the mountain hare. Even here nature has her lesson for those whose campaigns may extend far into the snows of winter. That horror, however, we are spared in our present trouble.

ON MAKING TRANSPARENCIES BY ELECTROSTATIC INDUCTION.*

IN following up the line of research indicated by my former paper in the *Photogram* of December, 1897, I have succeeded in obtaining some interesting results upon photographic plates; the energy emanating from a condenser plate which is subjected to a series of rapidly recurring electrostatic charges, is made to do the work of light, when allowed to act through an ordinary photographic negative or positive on glass. Some of these results I now record.

In order to produce a transparency on glass from a photographic negative, the apparatus required is of the same general construction as that described in my former paper only somewhat better insulated. Without going into unnecessary details of construction, Fig. 1 will fully explain matters.

The apparatus consists of a wooden box of rectangular shape, about 6in. by 5in. by 2in. (external measurement), and having inside a chamber of such size as to allow an ordinary ¼-plate negative to lie inside, and to leave a ⅛in. margin all round; this, to allow of strips of $\frac{1}{16}$in. ebonite being cemented round the sides—a precaution which I find necessary to prevent stray discharges taking place between the charged conductor inside and the wooden sides of box through ebonite discs or squares, let into suitable cavities in the upper and lower portions of chamber respectively, such that the disc of ebonite shall lie flush with the surface of wood. It is also desirable that a considerable portion of wood be removed from the centre of both top and bottom of the apparatus in the shape of a round hole about 1in. in diameter, passing right through the thickness of the wood. This is to allow a clear annulus of air all round the copper rods which form the electrodes. For purposes of insulation these might with advantage be filled in with paraffin wax. This is preferable to anything harder, because the rods must, by slightly twisting, be able to slide through the wax so as to bed the copper discs attached thereto evenly upon the negative.

Through these ebonite centre-pieces pass, fairly stiffly, pieces of ⅛in. copper rod about 2½in. long, and having attached, exactly at right angles, copper discs about 2½in. diameter one to each rod (on the ends which come inside the chamber). These discs may be cut from fairly flat and stout sheet copper, but are better turned in the lathe from thicker material which has been cast into thick discs, so as to be about ⅛in. thick when finished.

On the bottom of the chamber there is cemented a sheet of $\frac{1}{16}$in. ebonite (the disc and rod being removed for the purpose) of such a size as to exactly fit the rectangular space—i.e., before the strips of ebonite forming the side lining have been attached. Next attach the latter and finally fix to an area of the removable lid which is equal to and faces the bottom piece of ebonite (when the apparatus is screwed up for working), a piece of such size as will just fit into the diminished rectangle which results from attaching the ebonite side strips. Each of these ebonite bottom and top pieces must have in their centres a hole slightly exceeding in diameter the copper rods. These must be inserted from the inside and pushed right through until the copper disc rests upon the ebonite surface. They should fit just so tight as to remain in position until pressure or a twisting action be applied to the projecting extremity outside for purposes of adjustment.

It will be seen by reference to the diagram (Fig. 1) that the cover is removable and screws down upon velvet surfaces at the joint so as to be light-tight.

In order to produce transparencies on glass with this apparatus, take into the dark room and lay upon the bottom copper disc, film-side upwards, either an "ordinary" or "special rapid" plate, above this, film side downwards, a clear photographic negative. I find, curiously enough, that only wet plate collodion negatives can be relied upon for a good result. Upon the upper side of this negative arrange a (*metal, preferably*) ring of the same exernal diameter as the copper disc and about ¼in. to ⅜in. wide and made from $\frac{1}{16}$in. sheet metal. This ring may be cut from ebonite and may be covered neatly with tinfoil (a metallic rim seems to give the cleanest-cut edges to the transparency). Now screw on cover in such a manner as not to disturb the metal ring, which must be fairly central. Things being arranged thus, gently push inwards by twisting the rod projecting from the cover until it just presses the metal or ebonite ring evenly into contact with the negative (this is somewhat a matter of guesswork, but can generally be managed sufficiently well). Now connect up to a Wimshurst machine, as shown in Fig. 2, being particular to see that the positive terminal of machine goes to the copper rod projecting above the cover of the apparatus (i.e., the plate or disc of copper which lies above the negative becomes positively charged). The terminal balls must now be placed so close together (somewhere about ⅛in. or ¼in.) that, upon working the machine, the copper discs inside the apparatus immediately become charged, and at once discharge themselves across the small air gap between the balls of the machine. Sometimes, in damp weather, this sparking is obtained with some difficulty; for the best results it must take place rapidly with a decided clicking sound. Keep this sparking up for from half to one minute, according as you are using a rapid or ordinary plate.

It is important to note here that the time necessary is purely a matter for trial, and varies with the weather and the total thickness between the copper discs of the apparatus—that is, if the negative and dry plate be of specially thin glass the action is quicker than if of thick glass. In all probability, if both negative and sensitive plate were in the form of celluloid films the action would be much quicker, owing to the diminished distance between the charged discs. This I have not, however, tried. Should other readers try films in place of glass and get good or bad results, they might report their experience to the Editors.

In the dark-room the cover is removed, the dry-plate is taken out and placed in the developing dish with any ordinary developing solution, somewhat less alkali than usual being added. There should now appear very quickly an image of the photographic negative equal in area to the copper discs (that is, about 2½in. diameter) nearly large enough if cut down to make an ordinary lantern-slide.

My idea of how the latent image (in this case) is formed, is that the silver bromide molecules are normally arranged in such a condition that the bromide atoms lie in some other plane than that in which the film lies (and in this condition are undevelopable); that, after presenting to such a sensitive film a positively charged plate of metal, the bromine faces of the molecules either immediately turn into the plane in which the film lies, or partly so, and under the action of a succession of these efforts completely so; that they are developable only when turned into this plane. A photographic negative is really nothing more than a sheet of glass or celluloid having either clear glass or metal deposits of varying thickness. Where metal exists of sufficient thickness to obstruct light, it also cuts off completely the directing energy of the charged plate above it: where deposits of metal exist able to transmit a little light they also transmit a little energy of the plate; and lastly, where clear glass exists, the greatest transmission of plate energy takes place. The formation of the image results from a corresponding number of silver bromide molecules being turned into the plane in which they are most easily attacked by the developing solution which has the power, when rendered alkaline, of removing the bromine from the silver bromide molecules. Or something of the above kind takes place, and the bromine is then pulled so energetically from the silver with which it is combined that it, as it were, partially lets go of the silver, and is about to enter into some loose combination with the gelatine or other organic support, with which bodies bromine and iodine seem to be able to combine either physically or chemically. At all events, these combinations can easily be upset by the application of heat, as, for instance, iodide of starch is decomposed by heat. Reduction to the metallic state would in this case take place with great facility by applying some halogen-absorbing substance such as alkaline pyrogallic acid.

This seems to me to be the best way to look at the production of the latent image (at all events under a succession of electric induction charges), if not in the case of light itself which is a physical agent like electricity.

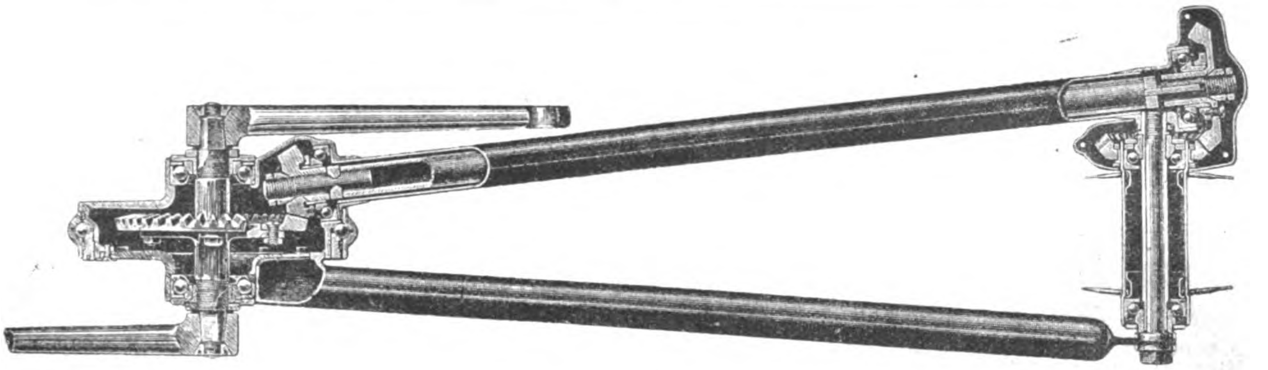
The editors of the *Photogram* append a note: "Mr. Whitworth's article touches a field of experimental photographic work which contains much that is obscure, and probably much that is likely to prove important. In the present state of our knowledge, facts are the things needed, the dearth of which makes theorising a tempting but rather profitless task. We shall be glad to hear from any readers who may repeat or extend the experiments here described."

* By JOSEPH WHITWORTH, in the *Photogram*.

THE PIERCE CUSHION-FRAME CHAINLESS BICYCLE.

IN order to relieve the rider of the shock due to inequalities in the road, many bicycle manufacturers have provided their wheels with cushioning devices, the most common form of which is a coil-spring located within the rear tube, and yielding under the weight of the wheelman. But the spring-supported saddle has the defect of changing the distance between the saddle and the crank-hanger, and thereby causes a loss in the application of power. With the object of providing a cushion-frame which would yield under the rider, but which would constantly maintain the distance between the pedal and the saddle, the George N. Pierce Company, of Buffalo, N.Y., have devised a novel arrangement which has very successfully withstood tests far more severe than those to which a bicycle is ordinarily subjected.

In the Pierce chain-driven wheel the usual spring is supplemented by a hinge-joint at the lower extremities of the rear forks, and by a flat plate-spring connecting the crank-bracket with the lower



rear tubes. From this construction it follows that, under the rider's weight, the entire frame will yield, and not merely the saddle, with the result that the distance between the saddle and crank-hanger will always be constant.

In the chainless bicycle it is evident that the flat plate-spring between the crank-bracket and lower rear tubes cannot be used, and that some arrangement must be employed essentially different in construction, but like in function.

With this end in view, the driving-shaft bevel-gear is mounted within a crank-bracket composed of two side-pieces firmly fastened together. In a central raceway on the outer periphery of the bracket, balls are placed which are received by a corresponding raceway in a bearing-ring rigidly connected with the lower front tube and the seat mast. The two side members of the crank-bracket, being firmly fastened together, rock on this bearing, and, acting in conjunction with the cushion and rear hinge joint, serve the same function as the flat plate spring previously mentioned.

Besides taking up the shock caused by obstructions in an uneven road, the cushion frame, with its rocking bearing at the crank-hanger, possesses the merit of relieving the wheel of much of the strain to which a bicycle is subjected, both in climbing hills and in riding over rough surfaces.—*Scientific American.*

THE ACTION OF STEAM IN THE CYLINDER.

FEW subjects connected with the steam-engine have produced more discussion, not to say wrangling, than the fall in pressure between the cylinder of a compound or triple-expansion engine, known as "drop," and represented on combined indicator diagrams as "gap," says *The Engineer*, commenting on a paper read before the North-east Coast Institute of Engineers and Shipbuilders by Prof. B. L. Weighton. The very title of Prof. Weighton's paper suggests a fray. He has, however, been careful to express no opinion whatever on this matter. He has prudently contented himself with setting before his hearers the results of his experiments, leaving them for the most part to draw their own general conclusions. He confines himself to particularities. His engine trials were made with a view to determine the most economical point of cut-off in the larger cylinders of multiple-expansion engines—that is to say, in the low-pressure cylinder of double-expansion, in the intermediate and low-pressure cylinders of triple-expansion, and in the two intermediate and low-pressure cylinders of quadruple-expansion engines. The specific object of the trials was to determine the receiver drop, "often referred to as free or intermediate expansion," between any two cylinders, with which was associated maximum economy; and incidentally to discover, in addition, the general effects of varying amounts of receiver drop in given conditions. We commend Prof. Weighton for his cautious use of the words quoted in the preceding passage. The triple-expansion engine tested has cylinders 7in. + 15½in. + 23in. × 18in. The trials were carried out with steam in jackets and without it. The steam-chest pressure was about 201lb. Experiments were also made with a compound engine. The general results of the trials as set forth by Prof. Weighton, are that for maximum economy of consumption, steam must be cut off at a certain point of the stroke in the larger cylinders of multiple-expansion engines. For any given cylinder this point depends solely upon the ratio between the capacities of that cylinder and the preceding cylinder R, and is expressed as follows, viz.:—

$$\frac{\text{Maximum-economy cut-off}}{\text{stroke}} = \frac{R + 6\cdot 6}{6\cdot 6\,R}$$

The cut-off in the larger cylinders, once fixed, should never be altered, whatever may be the cut-off in the high-pressure cylinder, or the steam pressure employed. This means that automatic-expansion governors, or linking-up gear, should act upon the high-pressure cylinder only, if maximum economy at all powers is to be preserved. The cut-off in the larger cylinders affects materially the total horse-power developed by the engines. As regards the low-pressure cylinder of triples, and the second intermediate and low-pressure cylinders of quadruples, maximum power cut-off in these cylinders coincides with the cut-off of maximum economy. As regards the second cylinder of triples and quadruples, maximum power cut-off is very considerably later than that of maximum economy. In compounds the maximum power cut-off in the low-pressure cylinder is only slightly later than that of maximum economy. Jackets have no material effect upon the cut-off of maximum economy; variation in vacuum capacity within practical limits has no effect upon the cut-off of maximum economy. Here is plenty of food for reflection. We may add that the brake-power of the engines, making about 140 revolutions per minute, was about 141 horses, the indicated power about 152 horses, and the consumption of water varied between about 14·4lb. and 15·98lb. per brake horse-power per hour.

Now, we venture to say that the formula quoted above will not necessarily hold good of any other engine working under somewhat different conditions. Furthermore, there are several points which are worthy of attention—one of these is the practical inefficiency of the jackets. It made next to no difference in the consumption of steam whether they were in use or not. Another is the small effect of wide variations in the points of cut-off on the economy of the engine. But, perhaps, nothing about the whole trials is more suggestive than the statement that cylinder capacity has next to no effect on the point of cut-off giving maximum economy. It is only the difference in capacity that operates. At the end of his paper Prof. Weighton gives the usual expanded combined diagram, and the saturation curve, in which "drop" is set forth graphically, and just in the right way to elicit discussion. We have more than once said in these columns that these combined diagrams are misleading, and it may be worth while to say so much once more. The gaps in such diagrams are very easily mistaken as representing losses of efficiency—dead loss, in fact—while, as a matter of fact, they merely represent losses of pressure, accompanied by augmentations of volume. That is say, we have so many cubic feet of steam at a given pressure, instead of a smaller number at a higher pressure. Of course, it must be understood that we except that element in drop represented by the actual condensation of steam. But for the moment we may neglect this. To make our meaning clear, let us suppose a single cylinder of considerable length in proportion to its diameter; on the side of this cylinder let a receiver be secured, and the communication between them effected through a valve, which can be closed or opened. Let, now, steam be admitted on the piston supposed to be at the end of the cylinder. After it has made a few inches of its stroke, the steam is cut off, and expanding, drives the piston before it. When the piston has passed the port opening into the receiver, steam rushes into the receiver from the working cylinder. The result is an immediate fall in the pressure behind the piston. This is "drop." The piston then goes on to the end of its stroke, when the valve of the receiver is closed, bottling up in it a certain weight of steam of the terminal pressure in the cylinder. The exhaust is then opened, and steam admitted at the other end of the cylinder. As soon as the piston passes the receiver port again, steam will, as before, rush in, and raise the pressure in the receiver at the expense of that in the cylinder. Again we have drop, and so the process is repeated stroke by stroke. Leaving, as we have said, all question of condensation on one side, a moment's thought will show that no matter what the size of the cylinder in proportion to that of the receiver, the whole weight of steam coming from the boiler must in all cases be available for work; and although it is quite true that the indicator card will show a drop at, say, half-stroke, yet it is certain that the diagram will be flattened near the end. According to all known laws of physics, the free expansion of the steam into the receiver cannot represent a loss, since no waste work is done; and it follows that the only source of loss is that represented by the circumstance that the steam is finally exhausted at a rather higher pressure to the condenser than would be the case if there was no drop.

Now, the receiver on the side of a single long cylinder gives conditions quite analogous to the two cylinders of a compound engine with a receiver between them. Prof. Weighton does not say what the condensation in each cylinder of his experimental engine was; nor does he give the distribution of power, so that we are unable to state what amount of work a pound of steam did in each of the cylinders. But it is known that in any good triple-expansion engine the available efficiency of the steam per pound is about the same in all the cylinders. It is further known that the capacity of the receiver has next to nothing to do with drop; that the amount of drop is settled mainly by the point of cut-off in the second and third cylinders, and that drop may, indeed, be wholly eliminated. Furthermore, in Woolf engines gap almost disappears, there being no intermediate receiver, yet it is well known that the Woolf engine is not so economical as that with an intermediate receiver. But the combined diagrams of a Woolf engine will show to much better advantage than those of receiver engines. In a word, the significance of a combined diagram is very small, and may, as we have said, be easily misleading, and we have further to remember that none of the diagrams show, or can pretend to show, what is the actual work done by the steam in the particular cylinder to which the diagram refers. Thus the high-pressure diagram only gives the net horse-power exerted, and not the total horse-power. But we have insisted on the importance of this point very often, and will not dwell on it now.

It is matter for regret that Prof. Weighton has said nothing to guide us as to the reasons why his experiments have given the stated results—why should the point of maximum economy for a cut-off depend solely on the capacity of the preceding cylinder? Perhaps Prof. Weighton has not yet made up his mind. The question is one of very great interest. We confess we do not see our way to answering it. Prof. Weighton contents himself with the bare statement, that "An examination of the whole of these results shows that the one and only factor which affects materially the cut-off of maximum economy in any one of the cylinders following the high-pressure cylinder is the ratio between the cylinder in question and the immediately preceding cylinder. In other words, the ratio between any two successive cylinders is the one factor which determines the point of maximum economy cut-off in the second of the two cylinders." It is fair to the author to give the following explanation in conclusion:—"This paper does not profess to deal with the questions of the best cylinder ratios or the best total number of expansions for steam of different pressures. The particular values of the cylinder ratios used in these trials are, therefore, of no economic significance, except in so far as they are associated with the best cut-offs in the larger cylinders of the engines."

THE EXPLOSIVE SIDE OF ACETYLENE.

IT is well known that acetylene gas when mixed with air is explosive, and Mr. F. A. McGahie, in the *Scientific American*, says that the experiments have given the limits within which the new illuminant must be produced and utilised to avoid dangerous and uneconomical conditions. Some cases deviating from those treated possess much interest in having found practical application, and having been studied from the point of view of possible explosion. Special burners have to be used with pure acetylene, as the ordinary ones do not give satisfaction with regard to illumination or economy. There is a deficiency in the supply of oxygen afforded by their construction, and combustion with them is not sufficiently complete to

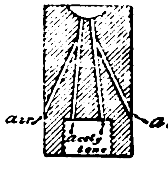


Fig. 1.

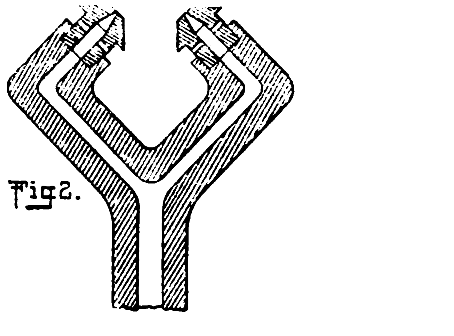

Fig. 2.

give rise to the temperature needed to carry to incandescence the large amount of carbon contained in acetylene. The first solution consisted in making the burners with holes, permitting air to be drawn in and mixed with the acetylene just before combustion (Fig. 1). Such would act satisfactorily for a time, and then begin to clog up and give a weakened, smoky flame. By adding 15 to 30 per cent. by volume of nitrogen to acetylene, Bullier was able to employ ordinary burners. Others have proposed carbon monoxide, carbon dioxide, hydrogen, water-gas, as diluting-agents. Of these, Prof. V. B. Lewes, Gas Engineer for the City of London Authorities, has stated :—The great trouble which has presented itself in diluting acetylene with any cheap diluent is that the illuminating power of acetylene is reduced to an enormous extent, and it has been found that hydrogen, carbon monoxide, and water-gas are useless for this purpose, as 10 per cent. of acetylene mixed with either of them gives a practically non-luminous flame, while if the acetylene is used in sufficient quantity to give a satisfactory light, the percentage of acetylene needed is too high to be commercially possible."

Prof. Lewes made a long series of experiments to discover a cheap diluent that "would maintain the enrichment value of acetylene at something near the value of the gas when burned alone. His conclusions were that "methane was the only gas that would do the work required, and further, that the presence of 30 per cent. of methane when mixed with hydrogen, carbon monoxide, or water-gas, converted it into an excellent diluent, with which 10 per cent. of acetylene gave a 20 candle-power gas, capable of being burned in ordinary gas-fittings." He found that each 10 per cent. of diluting gas mixed with acetylene raised the temperature necessary to originate explosion 180° Fahr. The practical value of this investigation lies, from our point of view, in the fact that a mixture containing enough acetylene to make a brilliant illuminant for railroad lighting can be compressed and utilised safely, since the temperature needed to cause explosion is high enough to melt the metal cylinders carrying the compressed gas. Such a system has been introduced with satisfaction on the street railways in Prussia. The preliminary tests were made by the Julius Pintsch Company, of Berlin, and the Prussian railway management in common. The conclusions of Berthelot and Vieille in regard to the explosiveness of acetylene were confirmed by these experiments. A tank was filled with acetylene at six atmospheres pressure, and a small pipe entering the tank was brought at a point 59in. from the tank to a red heat by a gas-flame. A violent explosion followed. Another tank was filled with acetylene at a pressure under two atmospheres, and a pipe heated as before at a point 59in. from the tank to a white heat. Local decomposition took place in the pipe, but no explosion occurred. With mixtures of 30 per cent. acetylene and Pintsch oil-gas, or coal-gas, compressed to as high a degree as was desirable, it was found that the fusible solder used in the joints of the tank would melt long before a temperature involving explosion of the compressed gas could be reached, and, further, that explosion did not result from heating highly the pipes leading to the tanks so filled.

For the small generator involved in the lighting of country houses by acetylene, the above methods are not available, and pure acetylene must be burned to secure a maximum simplicity of system. There are now satisfactory burners based on the principles of the one shown in Fig. 2. The escaping acetylene draws in air for mixing with itself, and the two jets impinge upon each other to form a vertical flame at a distance from the burner sufficient to avoid the overheating of the tops, with the consequent formation of the condensed polymers of acetylene, such as C_6H_6, C_8H_8, that causes smokiness and clogging-up with the burners of Fig. 1 type. It has been proposed to mix air in proper proportions for good combustion in usual gas fixtures with the acetylene after its generation, and a simple apparatus to this effect has been patented by Dickerson. But it involves an element of danger in introducing an explosive mixture into the distributing part of the system. The air can be mixed with the acetylene all right in the small passages of the burner, since the explosive laws of large masses do not hold in small tubes. Le Chatelier found that in tubes with diameter not exceeding 0 02in. any mixture of air and acetylene would not propagate explosion. The influence of the diameter of tubes is shown in this table determined by him :—

Diameter.	Inferior Limit of Inflammability. Percentage Acetylene.	Superior Limit of Inflammability. Percentage Acetylene.
0·03in.	7·7	10
0·08in.	5 0	15
0 78in.	3·5	55
1·57in.	2·9	64

There are some who hold that compressed, and even liquefied, acetylene, has a future. For compressed acetylene gas Claude and Hess have brought forward a method possessing distinct advantages, that of dissolving acetylene in acetone. At 60° Fahr. acetone dissolves about 26 grammes of acetylene per litre for each atmosphere of pressure, the factor decreasing with elevation of temperature. Berthelot and Vieille investigated this case to determine the conditions of explosion. They found that the acetylene gas above the liquid acted the same as pure acetylene, and would, therefore, detonate by a spark at two atmospheres and above. At pressures up to 10 atmospheres the acetylene dissolved in the acetone will not explode either through the detonation of the free gas or through the action of a highly incandescent wire placed in the liquid. Above 10 atmospheres a danger region is approached. In experiments at 20 atmospheres pressure inflammation of the free gas gave rise to an explosive pressure of 550 atmospheres. Since the decomposition of acetylene at 20 atmospheres would give a round 200 atmospheres pressure, it is evident part of the dissolved acetylene participated in the action. When the inflammation was provoked by an incandescent wire in the liquid part, a pressure of about 5,000 atmospheres was observed. In using cylinders charged according to this system it is imperative to take into account the fact that the pressure increases rapidly with the temperature In the charged cylinder experimented with a pressure of 6 5 atmospheres at 57° Fahr. became respectively 8·4 atmospheres at 80° Fahr., 10 2 atmospheres at 96° Fahr., and 15·8 atmospheres at 140° Fahr. It is desirable, then, in using acetylene dissolved in acetone to fix the charging pressure at 7 to 10 atmospheres, calculated for 60° Fahr., in order to obviate the danger of charged cylinders reaching, through exposure to the sun, or through being in the vicinity of some source of heat, a pressure at which the dissolved acetone would take part in any explosive decomposition. These figures have been given to exhibit the great increase of storage capacity afforded by the system. A cylinder of one litre capacity, carrying 0·7 litre of acetone saturated with acetylene at 7 atmospheres pressure, will carry 127 grammes of acetylene. The same cylinder will contain but 11 grammes of acetylene gas compressed to 10 atmospheres. If explosion should occur in the free gas of a cylinder properly charged, the maximum press obtainable would be below the safety limit of the cylinders employed, and the dissolved acetylene would be still available. The advocates of this acetone-acetylene method hold that it gives an excellent solution of the problem of storing acetylene in a condensed state in cylinders for subsequent transportation to any place where it is desired to feed a receiver, that it is more economical and safe than acetylene compressed in the ordinary manner, and that it is practically free from all danger in the hands of the skilled workmen who would handle the cylinders. Those who believe in the possibilities of liquefied acetylene have invented valves which make it impossible for ignorant workmen to open them too quickly, and to bring about thereby the danger of adiabatic compression in the gaseous column to a degree involving explosion.

THE *Cambrian Natural Observer* is the quarterly Journal of the Astronomical Society of Wales, and, as usual, is full of useful and interesting notes.

A LAKE of boiling mud exists near Grobogana, Japan. It is about two miles in circumference, and columns of steaming mud are constantly arising and descending.

SCIENTIFIC SOCIETIES.

BRITISH ASTRONOMICAL ASSOCIATION.

THE third ordinary meeting of the tenth session of the British Astronomical Association was held on Wednesday, Jan. 31, at Sion College, Thames Embankment, Mr. W. H. Maw, F.R.A.S., the President, in the chair.

The names of eleven candidates for membership were read and passed for suspension, and the election by the Council of seven new members was confirmed.

Mr. Holmes read a paper in which he first referred to the investigations of Prof. Schaeberle in regard to the defective definition of the Crossley 36in. mirror, and expressed his opinion that Prof. Schaeberle's grounds were sound and mathematics irrefutable, but thought there was an underlying misconception of the manner in which a mirror acts in producing an image. After describing the results of considering a mirror as made up of many small circular mirrors, and referring to the size of star discs from the various portions, as well as the many various planes in which they would exist, and after further describing the results of decreasing and increasing the size of the small mirrors of which the large one was supposed to be made up, Mr. Holmes went on to argue that this conception of a final image built up of superposed images in many planes and of many sizes was a mistaken one, and that the image of a star at the focus was not the result of such piling up, but was an interference phenomenon, the effect of the mirror taken as a whole, and not the effect of an assemblage of parts working more or less discordantly. The image of a star is not a composite image, not an accumulation of images, but is one only, and in one plane only. But the discussions upon the subject have treated a mirror as made up not of small mirrors, but as consisting of zones. This did not affect the reasoning. We are told that with a ratio of aperture to focus of 1 to 14 no discernible defect occurs. If we take a 12in. mirror of 80in. focus, the central 5½in. will give a practically perfect image, and, as we know, will result in a spurious disc about 0·8" in diameter. Now, according to Prof. Schaeberle, a zone ½in. wide round this will make a larger image and superpose on the original 0·8", and so on to the outer 12in. zone, which will produce the largest disc of all. Now, every one of the zones produces a larger spurious disc than the central aperture, and therefore their superposition cannot reduce the size of the disc produced by that central aperture, but must increase it, and therefore the larger the aperture the larger must be the star disc. This we know to be contrary to fact, and the reasonable inference is that the mirror acts as a whole in producing the focal image, and not piecemeal, and that the image is one only and not a composite of superposed images. If we study any zone alone the action is rather peculiar, for (still supposing it can produce a disc), then the rays from opposite ends of any diameter of an outer zone would produce discs in planes at an angle of 8° or 9° to each other, and every point of the annulus would make an image in a different plane to any other, and the sum of the action would be an image in a multitude of planes. But a narrow annulus of wide diameter has very little effect in producing a spurious disc at all. It throws most of the light into a ring with fainter rings both inside and outside it. These are mostly broken up by atmospheric unsteadiness, and the unsteadiness causes the flares and spikes, with which everyone is familiar who has experimented with narrow zonal stops. This failure of image is quite irrespective of the goodness of the figure of the annulus employed. I have so far referred only to a single or close double star in the optical axis. There must be some deformation of figure of disc as we depart from the axis of the telescope; but except for this the same considerations apply to other stars in the field as to one in the centre. They are equally the effect of the action of the entire mirror, and the definition of the stars in the outer portion of a star cluster would not be spoiled by the superposition or partial superposition of discs in different planes any more than the central star. And as the focal image of a body of sensible size, like a planet or the moon, is made up of points, and each point, like the image of a star, is the product of the whole mirror, and also, like that of the star, is as perfect as the slight inclination to the axis permits, the entire image is not made up of superposed images of different sizes and in different planes, but is one only. I think we must seek elsewhere for the cause of failure of large reflecting telescopes.

Mr. Seabroke said he had not had an opportunity of reading Prof. Schaeberle's paper, and, therefore, hardly liked to say he differed from the gentleman, or that he was in any way wrong; but from what Mr. Holmes said, it appeared that to treat a mirror for the purpose in question as consisting of a number of smaller sections or parts of a mirror was entirely wrong. The only proper method was to consider what took place when a wave of

light fell upon the surface of the mirror as it existed. It did not do to treat the matter simply geometrically—it was not a matter of geometrical optics—but one which should be treated from the point of view of a wave falling on the surface, and Mr. Holmes had certainly taken quite the right view of the matter. It was obvious that the image did not lie in an infinite number of planes just as they divided up in their own minds the surface of a mirror; but it existed in probably one surface only, and as to what Mr. Holmes had said with reference to the sizes of the several spurious discs, although he would not go so far as to say that, if they took a very small surface, the size of the spurious discs would be infinite, still it would be very large. If Mr. Holmes would consider those question from the wave-theory point of view, perhaps he would on another occasion give them a futher exposition of the matter.

Mr. Holmes, upon invitation by the President, said he could add something to what he had written. Prof. Schaeberle tested the 36in. mirror, he relates, by having a disc made 34in. in diameter, with a 12in. aperture in it. He placed the disc upon the mirror, and, having got the best focus he could, he found the 12in. central aperture with 8in. stopped out by the flat gave him only a fair image, and not a very good one. He examined the in-and-out focal planes with an eyepiece, and found he got a larger blurred image from the outer zone, and, on withdrawing the eyepiece, the image sprang into two rings, one larger than the other. This is what would be expected without any experiment at all, but Prof. Schaeberle appeared somewhat surprised at it. Then he found that the marginal 2in. ring (though if the mirror were 36in., and disc 34in., there would only be a 1in. ring left, and even if the mirror were 37in., which he understood was originally the case, it would only leave 1½in. ring) gave an image many times less bright than the central ring, although he says the outer reflected more than twice the light of the central portion. But he further tells us that the tube cut off some of the rays from this marginal zone, and the flat allowed more of what he calls the injurious rays to pass by it, so that, taken also with the larger image formed, he thought the result just what might be expected. A narrow annulus could not give a neat disc. If we wish to understand how it acts, we have only to consider the diffraction effects of a narrow straight aperture. This makes a straight bright line, with diffraction fringes on both sides. Now, conceive the straight line curved into a circle, and the result will be a bright ring with fringes inside and outside. Each annulus, in the experiment, made its own focal image, which images sprang apart on withdrawing the eyepiece as separate rings. The bad definition of the outer ring, taking the small tube and flat into consideration, would come from diffraction at the mouth of the tube acting as a stop, diffraction at the outer edge of the annulus, diffraction at the inner edge of the annulus, and diffraction at the edge of the flat—the result being a mass of diffraction fringes broken up by air currents, and not a disc at all. The central image being also the product of a narrow 2in. ring accounts for the merely fair disc that resulted from it.

Mr. Seabroke said Mr. Essam, of Billingborough, had sent him a drawing of Saturn, carefully executed, which was on the table for the inspection of members. Unfortunately, Mr. Essam did not give the date on which he made the drawing—it would probably be in May or June last. Mr. Essam informed him he was able to trace Cassini's Division just below the North Pole, and this remark, he says, corroborated Mr. Townsend's observations, which were, in short, to the effect that the fact of seeing Cassini's Division where he saw it showed that the measures of the diameters of the rings or globes of Saturn could not be exactly the measures of those diameters: either the measures, or the inclination of the plane, or something or other was out, or Cassini's Division could not have been seen in the place where he saw it. The drawing was made with a 12in. Newtonian reflector. Mr. Essam desired his name to be added to the list of members of the Saturn Section, and he (Mr. Seabroke) hoped other members of the Association would follow his example.

Mr. Crommelin read some notes on the total solar eclipse of 1900, May 28, which were accompanied by two diagrams; the first showing the position of the more important reference lines on the sun's disc at the time of the eclipse, and the second showing the stars and planets in the neighbourhood. The sun, he pointed out, would be in Taurus not far from Aldebaran. The 4th and 5th magnitude stars κ^1, κ^2, Tauri would be within the corona. To the left of the sun, Orion and Sirius; above, Auriga and Gemini; to the right, Perseus; while Mercury would be some 2° below and to the right of the sun, and as its disc would be fully illuminated and it would also be near perihelion, it would be quite a conspicuous object. In fact, the possessor of a good instrument might do worse than devote totality to a critical examination of Mercury. Venus at its greatest brilliancy in the middle of Gemini would be visible with the naked eye before the beginning of the eclipse, and would be resplendent during totality. There would be an unusual number of bright stars round the sun, and it would be interesting to see how many of them could be detected with the unaided eye. The Zodiacal Light might be visible during the expedition, though not to such advantage as it would be earlier in the year, but the probable clear skies and shorter twilight would be in its favour. Venus, Jupiter, and Saturn would be very favourably placed for observation. They might probably reckon on having sixty-four seconds of totality at Algiers. The *Nautical Almanac* data gave sixty-seven seconds; but from the experience of 1898 it would probably be less than this.

Mr. Maunder said that in 1895, when they were preparing to go to Norway, a number of papers were contributed to the *Journal* in the way of suggestions for observations that might be undertaken, and, thinking it would be found useful to follow a similar course in regard to the approaching eclipse, he had sought the co-operation of several of those who went to Norway in 1896 or India in 1898—viz., Miss Bacon, Mr. Johnson, Mr. Gare, and Dr. Downing. Proceeding to review the suggestions which had been made, Mr. Maunder said the observations of first importance which could be undertaken by those who had no large instruments at their disposal were first photographic, and next with the telescope. Photographs of the corona could be taken on a sufficiently satisfactory scale with fixed cameras, and therefore they need have neither equatorial nor driving clock. Instantaneous exposures might be given, and exposures up to one second, if they had the image of the corona on a scale of not more than half an inch to the sun's diameter, would be quite permissible, and would secure a very fairly dense image even to a considerable distance out. Then there were a large number of miscellaneous observations that a photographer could make. Miss Bacon, in 1898, in India, took a series of photographs of the landscape at regular intervals before the eclipse, and the result was to give a very striking picture of one way in which the illumination was diminished as the eclipse came on. It seemed to him that that experiment needed to be repeated, and with a very much larger number of photographs on the next occasion; and it would be as well if this were done at three or four stations, if so many were occupied. Then he would like to see repeated the experiment (for which Mr. Gare and Mr. Johnston prepared the plates, exposures being made by Mr. E. W. Johnson) on the brightness of the general corona; that was to say, a photographic plate was exposed for a graduated series of seconds or else under a sensitometer to the full light of the corona, not in the camera but simply by exposing the plate. In that way they might get a useful record of the total brightness of the corona from eclipse to eclipse, such as, before the Indian eclipse, had never been secured. Then with small telescopes a good deal of useful work could be done—telescopes with an aperture of from 2in. to 4in., and with an ordinary tripod stand. Perhaps the most important work that could be done with a telescope of that description would be the drawing of a small isolated portion of the corona. That had never yet been satisfactorily attempted; and certainly a good draughtsman, confining himself to a small portion of the corona, could add considerably to their knowledge of its structure. It was not the slightest use for a draughtsman to entertain the idea of sketching the whole corona. One small section alone, and that a typical one, would be of very great value. Probably the most important thing to do would be to pick out a bright prominence and sketch the corona in its immediate neighbourhood, because the particular region of the corona could be determined from the photographs. Next to that, one of the polar plumes would be a very good object for scrutiny. A telescope of the size he had mentioned would be very useful in order to give them the times of contact, and there were a number of small phenomena that it would be interesting for the observer to watch; for instance, the appearance of Baily's beads, the distance to which the moon's limb could be detected on the background of the corona, and away from the sun, and a number of similar small details. One very important point which the possessor of a small telescope could determine would be to forecast beforehand, within a few seconds, the actual beginning of totality. Having explained various ways in which this could be done, Mr. Maunder proceeded to say that shadow-bands had been observed for a great number of years; but more observations were needed, and these should be conducted at each of the stations. It was distinctly advisable that they should be observed both on the horizontal plane and in the vertical plane, and that the observation should be made in such a way that the exact direction of the motion of the shadow bands should be determined. Remarking that in shadow-band observations the direction of the wind was a very important point, Mr. Maunder said this would lead to the question of meteorological observation. In Norway their one successful observer was Mr. Mitchell, who took a number of meteorological observations, and he hoped that at each station next May one person would imitate Mr. Mitchell's example. Then, Mr. Crommelin had already pointed out how very favourable this eclipse would be for the observation of stars. The sun could not well be in a richer portion of the heavens, and those who had no instruments at all could well occupy themselves during totality in identifying as many stars as possible. They should study Mr. Crommelin's map well beforehand, so that they might know exactly where to look for stars and planets. The sun, of course, would be one point of reference. Venus would form another, for she would be visible no doubt before the beginning of the eclipse, and certainly very early in the partial phase she would be a brilliant, unmistakable object, so that they should be able very easily to get the bearing of the other stars with relation to those two points. Mercury would probably also be quite a conspicuous object. Usually only two or three stars were noticed during a total eclipse, but in the present case he expected they would have a great many more. Mr. Shackleton had suggested to him that there was one kind of photographic observation that it would be well for some photographer to undertake—viz., to photograph the corona with light as nearly as possible monochromatic, by the use of a special sensitive plate and a coloured screen. The active rays on the plate should be cut down as nearly as might be to the green given by the coronium gas. It would be a matter of very great interest if that could be done. It would be very much cheaper than to arrange for a heavy spectroscopic battery, and probably would give the distribution of coronium pretty nearly as effectively as would the spectroscope. The same could be done perhaps more easily for the line of hydrogen by selecting, partly with a coloured screen and partly with a special sensitive plate, just the region that corresponded to the blue line of hydrogen. During the eclipse of 1898 it occurred quite independently to two or three observers—Mr. Backhouse, a friend of his, and himself (the speaker)—in different places to try and compare the twilight illumination in the evening with the illumination during totality, and their attempts, made without the slightest knowledge of what the others were doing, gave an extremely gratifying concord. Of course, Spain not being in the Tropics, the twilight would not be so rapid as in India; but he thought this experiment was worth trying, and he would be glad if everybody who was fortunate enough to view the eclipse would remember this on the evening after the eclipse, and try and fix accurately the time when the illumination in the sky corresponded to the illumination during totality.

Mr. Seabroke desired to ask Mr. Maunder the proportion of focal length to the aperture of the camera lens to which he had referred when he said the exposure might approximately be taken at 1 sec. for the corona. It occurred to his mind while Mr. Maunder was speaking, that in 1870 Prof. Thorpe made some experiments on the change of general illumination; but in those days only sensitive paper was used—dry plates not then being known—and this was passed under circular apertures and exposed for a certain time.

Mr. Crommelin wished to ask Mr. Maunder how nearly he thought the screens to which he referred could be made to only transmit a light of one colour. He understood that the light of the corona was made up of two elements—one a continuous spectrum, and the other bright lines. Unless they could make their colour screen to transmit practically only one colour, the continuous part of the spectrum might get mixed up with the one colour they were trying to photograph, and might lead to confusion in the result.

The President said a good deal had been done in the way of getting monochromatic screens for microscopic work, and he thought some of the screens produced did admit light of a very limited range of wave-lengths, but, possibly, not confined to the part of the spectrum which Mr. Maunder desired to deal with.

Mr. W. H. Wesley said that he warmly endorsed Mr. Maunder's recommendation to those who drew to restrict themselves to small portions of the lower part of the corona. He had long urged upon those who proposed to make hand drawings; the uselessness of attempting to delineate the whole. The only further service that a draughtsman could render had been in drawing the extreme extensions of the corona, but since the remarkable photographs that Mrs. Maunder took during the eclipse of 1898, it seemed evident that photography would do that perfectly. Those who make hand drawings should therefore take some portion of the corona near the limb. We shall not advance in building up the corona from the projection of it seen during an eclipse without an exhaustive study of the lower coronal rays.

In reply to Mr. Holmes, who asked what would be the probable temperature at Algiers at the time of the eclipse, Mr. Crommelin said a guide-book he had consulted stated that the temperature varied very little throughout the year. It was 14° C. in January, and 24° in August, which was a range of 10° C. or 18° Fahr. during the whole year. The mean between January and August would be 19° C. or about 66° Fahr.

Mr. Downing: That does not represent the temperature at three o'clock in the afternoon.

Mr. Crommelin: No; that is the mean of the day. (Another guide-book gives 69° Fahr. as the mean temperature in May.)

The President, referring to what Mr. Maunder had stated as to the use of a screen, said that if he could determine a range of wave-lengths that he thought would be useful, and would give particulars of it at the next meeting, some of the members who had been paying particular attention to the construction of screens for monochromatic work would very possibly go into the matter, and probably they might be able to evolve a standard screen suitable for employment in the way Mr. Maunder had suggested. It would be very desirable not only that a screen of approximately the true colour should be used, but that all screens should be very closely alike. Mr. E. M. Nelson and Mr. Curties had made a great many experiments on the production of a standard screen for microscopic work, and probably they would aid in the matter if asked.

Mr. J. J. Vezey said that Mr. Giffard, of Chard, had devoted great attention to lens subjects, and had been very successful in producing screens for transmitting monochromatic light.

Mr. Maunder said, with regard to Mr. Seabroke's question as to the relation of aperture to focal length, he had in his mind such a ratio as 1 to 15 or 1 to 16. Of course, if the aperture were relatively greater to the focal length, the exposure might be shorter. With regard to the question of the screens, his notion was that one might work in two directions—one by limiting the sensitiveness of the plate, and the other by limiting the quality of light transmitted by the screen. He thought the combination would give them greater control of the exposure than the one alone would. Practically, the hydrogen line, in his opinion, would be far easier to compass than the coronium line. He ought to have mentioned amongst the eclipse suggestions the drawing of the corona with the naked eye, which was carried out so successfully in India in 1898; but he was more impressed to lay stress on the drawing of the corona at the telescope because it had been so entirely neglected on former occasions, and he would be glad to see it restored to a place in regular eclipse observations. With reference to the proposed expedition to view the eclipse, the committee had made a provisional arrangement with the Royal Mail Steamship Company for the conveyance of the party by one of their finest vessels, the *Tagus;* but at present the number of members who had actually engaged their berths and paid their deposits was only about half that required to make the expedition a success. He hoped, therefore, members who were thinking of doing so would send in their names and their deposits without further delay; otherwise, the proposed expedition would have to be abandoned. The Association, of course, could not enter upon a speculation in the matter, and as they were not providing for making any profit in the matter, they could not take any definite step until they were perfectly certain of such an amount of support as would insure the Association against the risk of loss. The Royal Mail Company had extended the time for signing the contract to Feb. 12. If by that date a sufficient number of passengers had actually engaged their berths, the steamer would be secured. If not, the idea of engaging a steamer must be entirely abandoned. He (the speaker) felt sure that if this was the case, a good number who were now holding back would, when they found how difficult it was to make satisfactory arrangements, regret exceedingly that they had let so good a chance fall through.

The President said it would be a very serious thing for the Association if the proposed expedition were to fall through, and he hoped members would do their best to get their friends to make up their minds immediately, and communicate with Mr. Maunder on the subject. The support the committee had received up to the present time was only about half large enough. The matter had been thrown back a good deal by the war in S. Africa, which had affected a great many people, and had been the means of crippling the Irish expedition, which was to have been organised on the same lines as that of this Association. The Royal Dublin Society, the Irish Academy, and two other societies had expected to send out an expedition of 140 members; but this number had dwindled down to six, who intended, under the circumstances, to take part in this Association's expedition. They had themselves been affected in the same way, and although things did not look very rosy at present, he hoped they might yet organise a successful expedition.

In a paper on "Where the Day Changes" Dr. Downing pointed out that when it was six o'clock of the afternoon of Wednesday in London, to the eastward-going traveller, upon reaching the 180° of longitude, it was six o'clock of the morning of Thursday; whilst to the westward-going traveller reaching that point it was, at the same time, six o'clock of the morning of Wednesday. To set things right, therefore, it was necessary, in the first case, for the traveller to call two successive days "Thursday," and in the second case, omitting the Thursday altogether, to pass from Wednesday to Friday. This was the practice observed in ocean-going ships, when crossing the 180° of longitude. Dr. Downing proceeded to deal with the question of where the day changes for the portion of continents and the islands contiguous to the 180° of longitude, or, in other words, the course of the date line, as it is called, from the Arctic to the Antarctic regions. With the aid of a map he dwelt upon the strange disagreement which exists at the present time in the position of the date line laid down by the different authorities, pointing out, however, that Wharton and Davidson only differed in one particular, affecting a small group of islands.

Dr. Downing added that a good deal had been heard recently about when the century began, and he had been amazed at the ignorance of history and arithmetic which had been displayed. It was declared by some that the century began on Jan. 1 last; but, as a matter of history, that is quite wrong. Proceeding to deal with the history of the subject, the speaker said that about the middle of the 6th century of our era—in 530 A.D.—the Roman abbot Dionysius looked into the question, as there was considerable confusion at the time, and the Christian community, which was then becoming large and powerful, wished to reckon time from the birth of Christ, and not from the foundation of the city of Rome, as was the practice in those days. Dionysius investigated the question as far as it was possible to do in those days, and he decided that A.D. 1, the first year of the Christian era, coincided with a certain year of the City of Rome, and, according to his calculations, our Lord was born on the 25th Dec., B.C. 1, but he did not wish to upset the Roman usage of beginning the year on Jan. 1, so that it was settled then, and the practice had continued ever since, of calling the first year of our era A.D. 1 and beginning the year on Jan. 1. It was a mere matter of arithmetic to conclude from that that the 20th century must begin on 1901, Jan. 1. The little map, therefore, which he had prepared would show where the day began, and the historical sketch he had given would, he hoped, show when the century began.

Mr. Crommelin remarked that Dr. Downing's very interesting paper cleared up in a most lucid manner a question one was often asked. It had hitherto been difficult to give a very definite answer to the question; but they could now simply point out the exact place where the day began. It was rather a curious anomaly that for twenty-four hours a portion of the earth would be in one century and another portion in another. He might even go so far as to say for thirty-six hours, for there were two different methods of reckoning the beginning of the day, the civil day commencing at midnight and the astronomical day at noon, so that at Greenwich they were accustomed to using the date of the old year until noon on January 1st. There would thus be twelve hours when for one purpose one would be in the 19th century and for another in the 20th century; and if they extended that right round the world and added the twelve hours to the twenty-four hours' rotation, it would make thirty-six hours of ambiguity.

Mr. Kennedy asked whether it was not perfectly true that the birth of Christ was three years B.C.? If so, that rather added to the difficulty. They had also to take into consideration the Old Style, in which there was a difference of thirteen days as compared to present-day reckoning; so that, quite apart from the three years, the 19th century would go on for another thirteen days if they took the Old Style into account.

A Member remarked that in the East they did not hold to Dec. 25 as the date of Christ's birth. He had been told by missionaries that it was reckoned to be somewhere near March.

Dr. Downing agreed with Mr. Kennedy that it was quite probable the reckoning of Dionysius was three, or even five, years wrong; it depends on the identification of the Governor of Syria, mentioned by St. Luke; but that, he submitted, did not affect the question at all. The first year of our era was called A.D. 1, and we still called that year A.D. 1, and counted on from it. Neither did it matter, in this connection, whether Our Lord was born on Dec. 25 or not. He (the speaker) did not hold to that himself—but it did not affect the question at all. The point was that Dionysius decided that the birth of Christ took place on Dec. 25, B.C. 1, and therefore the Christian era was to commence from the following Jan. 1.

Mr. Goodacre read a paper by Mr. C. F. Smith on "The Palus Nebularum Region of the Moon," in which, in the light of recent views regarding the origin of lunar surface features, he explained some of the formations of the Palus Nebularum, dealing also with many similar regions in different portions of the surface. The paper was accompanied by an illustration of the region taken from an oil painting in monochrome, copied from pastel drawings made during the spring of last year. Dealing with the question of the probable history of the region, judging from its various features, the author said:—"In the first place, this part of the moon's surface was at one time completely covered with mountains and crater-formations, the latter of a size not less than Theætetus. In course of time, a large area became depressed (probably through contraction of the cooling interior), and liquid material welled up through cracks and rents in the surface. This gradually spread, covering many formations entirely, almost wrecking Cassini, and reaching the northern and western walls of Archimedes in a viscid state, but ceasing to rise before breaking down the massive ramparts of that crater. Although upheavals and elevations on the most gigantic scale were now at an end, internal activity continued to manifest itself in the formations of the craters Theætetus, Kirch, Piazzi Smyth, and the numerous smaller openings freckling the surface of the *mare*. The interiors of Autolycus and Aristillus filled with liquid which flowed through the cracks and gorges in their walls, and spread in radiating streams far over the surrounding plain, while, again, the form taken by the escaping fluid was that of an 'exudation cone,' which gradually and quickly built itself up. To put in concise form the fourth order of formation, we have:—(1) The Caucasus and Alps. (2) The craters Archimedes, Autolycus, Aristillus, Cassini, and others now buried. (3) The dark plain of the Palus. (4) The craters Theætetus, Kirch, and Piazzi Smyth. (5) The mountain mass Piton. (6) The minute craters on the surface of the *mare* and elsewhere. The most doubtful date is that of Piton, which may possibly be a protruding peak from an early mountain range; but, on the whole, it is more probable that it was formed after the sea."

Mr. Goodacre said that in the main he was rather inclined to agree with what Mr. Smith said as to the chronology of the various formations. He had some doubt, however, as to whether Mr. Smith's theory to account for the radiating ridges was one which could be altogether accepted. It appeared to him that they were not ridges of lava which had overflowed from the rim of the crater, for, as far as his own observation went, there was no appearance of cracks or gullies in the walls which would form apertures through which the lava would flow. This was a phenomenon which was accounted for by the sudden upheaval of the mountain ring itself.

Two slides were then thrown on the sheet which had been prepared from instantaneous photographs of a boiling mud crater in the N. Island of New Zealand, within twenty miles of the well-known volcano whose eruption some time ago destroyed the beautiful terraces of pink and white. As Mr. Goodacre remarked, these slides showed details very similar in appearance to what was seen on the moon, and the study of such terrestrial features might throw a considerable amount of light on the way in which the lunar craters had been formed.

Mr. Hardy said some lunar formations were described as being 7,000ft. high, and other parts of moon's surface 10,000ft. deep; but, in the absence of anything similar to ordnance data, no one knew what the depth and height were from the mean level of the moon. If such ordnance data were taken—and it did not appear to be impossible—they would be able to speak of the heights of the mountains above that surface and the depths of the hollows below it.

Mr. Crommelin said there would be great difficulty in ascertaining the difference of level between two distant plains on the moon. There was on the moon no liquid surface to give a uniform standard of measurement as we had on the earth. They could only measure heights by the shadows, and where the surface had so slight a slope as to throw no shadow he did not see how they were to get the relative heights of two flat regions some distance from each other. The only way in which to do this would be to take advantage of the libration of the moon and take two photographs at extreme libration, and compare the forms in one and two. Some result might be obtained by that means; but it would be a laborious and difficult task.

Mr. S. A. Saunder said that our knowledge of lunar altitudes was very insufficient—we did not know the heights of the mountains within 20 or 30 per cent. If anyone would open Schmidt's book at random, and take any mountain he had measured ten or a dozen times, it might be found that its greatest height was double its smallest—it would very frequently be 50 per cent. greater, so that there was little or no possibility of their getting any accurate measures of levels as yet, and he thought it would be exceedingly difficult to compare the level of one plane with the level of a distant plane. Dr. Weinek, a short time ago, published a pamphlet in which he described how he found the height of Pico by measurements made on photographs, deducing the sun's altitude from Mädler's position of Pico by computation. He measured it on three or four photographs, and obtained very consistent results, very much more consistent than those obtained by Schmidt. As the position of the mountains of the moon became known more accurately, so that the altitude of the sun could be computed, they would have a very good chance of arriving at the height of the mountains. He doubted whether Mr. Smith was accurate in saying that MM. Lœwy and Puiseux placed the date of the formation of such craters as Autolycus and Aristillus previous to the

formation of the seas. His own idea was that they placed the date later. MM. Loewy and Puiseux divided the history of the formation of the lunar surface into five periods, and he was almost certain that Copernicus, which was a mountain much like Aristillus, was placed in the last period as having been formed after the plain. They said some of the ringed mountains were formed in an early period, and some after the large plains, and that the formations in the latter period could be distinguished by the regularity of the formation of the wall, by their isolated situation.

The meeting adjourned at 7 p.m.

ROYAL MICROSCOPICAL SOCIETY.

AT the annual meeting, Mr. E. M. Nelson, the President, in the chair, the President said it was with very great regret that he had to announce the death of the Treasurer, Mr. W. T. Suffolk. He was an old member of the Society, having joined it in 1863. In addition to acting as Treasurer for some years, he had examined and catalogued the slides, about 7,700 in number, in the Society's cabinet, and had remounted a great number of them which had been found to be leaking, or otherwise imperfect. A resolution expressing the great sympathy of the Council with Miss Suffolk, and also acknowledging her gift of her uncle's cabinet of slides, was read to the meeting, and at the request of the President the Fellows present endorsed the action of the Council by show of hands. After the report of the Council for the past year and the statement of accounts had been read and adopted, the President announced that the following had been elected as officers and Council for the ensuing year:—President: Wm. Carruthers; Vice-Presidents: A. W. Bennett, G. C. Karop, A. D. Michael, E. M. Nelson; Treasurer: J. J. Vezey; Secretaries: Rev. Dr. W. H. Dallinger, Dr. R. G. Hebb; Ordinary Members of Council: J. M. Allen, Conrad Beck, Dr. R. Braithwaite, E. T. Browne, Rev. E. Carr, E. Dadswell, Sir Ford North, H. G. Plimmer, T. H. Powell, C. F. Rousselet, Dr. J. Tatham, G. Western; Curator: C. F. Rousselet. The President then delivered the annual address on the work done during the past year in connection with the Society, including the standardisation of the substage and eyepieces, and concluded by reading a paper, which was a continuation of the optical subjects dealt with in his previous addresses, and had special reference to the aplanatic oil-immersion front and the construction of the Huyghenian eyepiece. Mr. Michael proposed a vote of thanks to the President, not only for the address which they had just heard, but also for his eminent services to the Society during the time he had occupied the chair. In this period he had given a series of addresses which will form an admirable record of the practical application of the principles upon which the optical part of the microscope was constructed. Dr. Braithwaite having seconded the vote of thanks to the President, it was put to the meeting and carried unanimously. The President then introduced his successor, Mr. Wm. Carruthers, who, having taken the chair, made a short address to the meeting. Mr. Rousselet exhibited a mounted specimen of *Stephanoceros Eichhorni*, a rotifer which is very difficult to kill with its cilia fully extended; but, after many trials, Mr. Rousselet has succeeded in overcoming the difficulty, and the specimen exhibited presented a very life-like appearance.

LOCKWOOD'S BUILDER'S, ARCHITECT'S, CONTRACTOR'S, AND ENGINEER'S PRICE BOOK for 1900, edited by Francis T. W. Miller (London: Crosby Lockwood and Son), is the new edition of a well-known annual which all interested must have this year, as prices fluctuated considerably during the last.

FOURTEEN ten-wheel two-cylinder compound locomotives have been built at the Schenectady Locomotive Works, for freight service on the Northern Pacific Railway. These engines weigh 78½ tons, of which 60 tons are carried by the six-coupled drivers. The heating-surface is 3,012·7sq.ft., and the grate area 34·22sq.ft. The boiler is of the extended waggon-top type, the first ring being 70in. in diameter. The driving-wheels are 63in. in diameter, and the cylinders 22in. and 34in. by 30in. The high-pressure cylinders have piston-valves.

Lightning and Trees.—As a result of observations carried out by the German Government on lightning and its effects on trees, it has been found that the oak tree is by far the most susceptible to the attacks of lightning. The observations were made by the overseers of nine foresting stations scattered throughout an area of 45,000 acres in the dukedom of Lippe. The percentages of the various species of trees in the forest are as follows:—Beech, 70 per cent; oak, 11; pines, 13; and firs, 6. During a period of several years 275 trees were struck, of which 159, or 58 per cent., were oaks; 59, or 21 per cent., firs; 21, or 8 per cent., beeches; and only 20, or 7 per cent., pines; the amount of damage sustained by other species being still smaller.

SCIENTIFIC NEWS.

AT the annual general meeting of the Mathematical Association it was announced that the Mathematical *Gazette* will in future be issued six times a year instead of three. As the aim of the Association is to supply a serial of direct and special interest to teachers of mathematics, it is intended that amongst the special features of the *Gazette* there shall be articles suggestive of improvements in methods of teaching, or covering ground not satisfactorily treated in textbooks, with reviews of books of the first importance, or giving an elementary presentation of the history and treatment of their subject.

With the beginning of March a new almanac complication will arise in Russia, says the Odessa correspondent of the *Standard*:—Owing to the fact that this year is bissextile with the Russians, Greeks, and Balkan Slavs, who still retain the Old Style chronology, there will ensue a difference of thirteen, instead of twelve, days between the Julian and Gregorian Calendars. Feb. 1, Old Style, becomes the 14th, New Style, instead of the 1st—13th, as heretofore. After all the talk of the last twelve months, there is no immediate prospect of a rectification of the calendar being made in Russia. The Church is bitterly opposed to the suggested reform; and the various learned societies which have latterly discussed the question are utterly divided in their views and opinions. Personally, the Emperor Nicholas is known to favour the long-mooted project for adopting the Gregorian reckoning. The necessity of a calendarial assimilation with Western Europe becomes every year more pressingly felt with Russia's rapidly-increasing commercial and industrial development, and her enlarged and enlarging intercourse with Western nations.

According to the official reports the fall of snow on Friday-Saturday last seems to have been one of the heaviest—at any rate in recent years. In many parts of London it melted rather quickly, but at the reporting-station of the Meteorological Office at Brixton the total fall when melted gave ·74in., equal to a fall of snow of between 6in. and 7in. At Westminster the melted snow yielded ·63in., but in parts there were drifts, and the hands of the clock at the Houses of Parliament (sometimes called Big Ben) were stopped just before 2 a.m. on Saturday—those on the face most fully exposed to the force of the blast being clogged with snow.

According to the Berlin correspondent of the *Standard*, Prof. Assmann states that the Royal Prussian Meteorological Institute in Berlin is about to make arrangements for the systematic examination of the higher strata of the atmosphere by means of special apparatus. The registering apparatus, which automatically notes the pressure, temperature, humidity, and wind velocity, is taken up by a kite-balloon connected with the earth by piano wire. It is inflated with hydrogen, and can take fifteen hundred mètres of wire. The control of the kites is effected by means of electrically-driven windlasses.

The addition to the Engineering School of Cambridge University, erected in memory of the late Dr. John Hopkinson, was formally opened on Friday last. Dr. John Hopkinson was Senior Wrangler in 1871, and took great interest in the Engineering School, and a few days before the fatal accident had expressed an intention of making a movement to secure funds for an enlargement. This has been accomplished now by the generosity of his widow, son, and daughter. The memorial is most appropriate, and engineers and others have responded handsomely in fitting up the laboratory and in providing apparatus. After the Vice-Chancellor had formally opened the building, Lord Kelvin (Master of Trinity) delivered an inaugural address, in which he said that John Hopkinson showed to quite an exceptional degree the rare power of grasping a high scientific truth, and applying it practically to mechanical art for the use of mankind. This was splendidly illustrated in the work which he did in improving the dynamo-electric machines, upon which we depended so much for light and power. Then there was his great discovery of a certain alloy of nickel and steel. Hopkinson's group-flashing light, a splendid application of scientific optics, was now in use in lighthouses and lightships all over the world. Everything that was for the good of clients, of engineers, and of the engineering profession itself Hopkinson had at heart.

M. Daniel Osiris offered the Institute of France a sufficient sum of money to found a triennial prize of a hundred thousand francs (£4,000) for the most remarkable discovery or work in science, art, or letters. It is announced that the Institute has accepted the gift on the conditions laid down by the donor.

University College, Liverpool, is to have a completely-furnished botanical institute, the gift of Mr. W. P. Hartley. The building, which will be erected close to the new chemical laboratories, will contain museum, lecture theatre, laboratories, library, herbarium, and private rooms, is expected to be opened early in 1901.

At the meeting of the Royal Society at Burlington House, last week, a paper was read describing some of the results of a remarkable investigation which has been undertaken by Prof. Dewar, Sir James Crichton-Browne, and Prof. Macfadyen, who have submitted a large number of disease-causing microbes for prolonged periods to the temperature of liquid air, which is $-190°$ C., and have found that they are not a bit the worse. After twenty hours of this frigid environment the bacteria proved as lively as ever. Doubt is thus thrown on the popular belief that a sharp frost can cut short epidemic disease, for frost is genial warmth when compared with the terrible chills administered in the laboratories of the Royal Institution. The photogenic or light-giving bacteria went out when immersed in liquid air, but resumed their luminosity when thawed and warmed up again. The microbes are to have a dose of liquid hydrogen shortly, and if they stand that they can stand anything.

At the meeting of the Royal Geographical Society on Monday, Dr. H. R. Mill read a paper on "The Geography of South-west Sussex," a specimen of the scheme he suggested in 1896 for drawing up a geographical description of the British Islands based on the maps of the Ordnance Survey. The idea is to compile a handbook calling attention to the main features of the land surface, and then to add a description of the climate, the agriculture, the trade, and the movements and distribution of population from the different official returns. The paper dealt with the Rother Valley and the Chalk Downs, and is a specimen of what might be done for every district in the kingdom. Dr. Mill finds that the coastal plain has an average density of population close on 400 per square mile, or one-third more than the average for England. On less fertile soils of the Rother Valley the density of population was only 200 per square mile, and on the Chalk Downs above 300ft. only 14 per square mile, the contrast between the three regions being even greater in population than in agriculture. Farming was the staple industry. There was no mineral wealth except chalk, flints, brick-earth, and here and there sandstone. Taken altogether, the district was a typical sample of rural England, untouched by manufacturers or trade, practically stationary in population except for the yearly increasing influx of summer visitors, and the seat of a remarkable number of parks and historic houses.

The following officers have been elected for the Association of Technical Institutions:—President, Sir Swire Smith. Vice-presidents: Lord Spencer, Sir Bernard Samuelson, Bart., Mr. H. Hobhouse, M.P., and Mr. W. Mather. Treasurer, Mr. R. F. Martineau (Birmingham). Hon. sec., Prof. J. Wertheimer, B.Sc., B.A. (Bristol).

At the meeting of the Society of Arts, on Wednesday, Feb. 14, Prof. R. W. Wood is to read a paper on "The Diffraction Process in Colour Photography." Sir W. de W. Abney, K.C.B., F.R.S., will preside.

A memoir has been recently presented to the Paris Academy of Sciences by M. Frillat, which is of interest to students of the science of photography. It refers to the transformation of the photographic image of a negative into the lamellar state by exposing it to the vapours of nitric acid, which dissolve the precipitated silver, and cause the disappearance of the image. The silver is reprecipitated by exposing the plate in an atmosphere of moist sulphuretted hydrogen, when the image reappears in colours—not necessarily the true colours of the objects, although, it seems, there is some possibility of exercising a little control.

Sir Thomas Grainger Stewart, Professor of the

Practice of Physics and Clinical Medicine in Edinburgh University for nearly a quarter of a century, and an ex-president of the Royal College of Physicians, Edinburgh, died on Saturday in Edinburgh, at the age of sixty-two. He was educated at the High School and University of Edinburgh, graduating M.D. in 1858, and subsequently pursued his studies at the medical schools and hospitals connected with the universities of Berlin, Prague, and Vienna. After his return to his native city, he was elected a Fellow of the Royal College of Physicians there, and appointed Resident in the University Wards of the Royal Infirmary. This position gave him opportunities for the study of the special forms of disease to which he particularly devoted himself, those connected with the kidneys, and led to his appointment as Pathologist to the Royal Infirmary and Lecturer on General Pathology at Surgeons' Hall. After filling with great success these offices for between six and seven years, he was, in 1869, elected Junior Ordinary Physician to the Royal Infirmary and Lecturer in Clinical Medicine. He held these posts until 1876, being also, from 1873 to 1876, extra-mural Lecturer on the Practice of Physics, and Lecturer on the Practice of Medicine. In the last-mentioned year, on the death of Dr. Thomas Laycock, he was elected to the Chair of Medicine in the University of Edinburgh, which he most efficiently filled. Sir Grainger Stewart was the recipient of many honours, and was a member of many learned societies in Europe and America. He was the author of several valuable treatises on medical subjects.

The well-known orthopædic surgeon, Mr. William Adams, died on Saturday last, aged 80. He was admitted a member of the Royal College of Surgeons, England, in 1842, and elected a Fellow in 1851. He was Lecturer in Surgery at the Grosvenor-place School of Anatomy and Medicine, Demonstrator of Morbid Anatomy and Conservator of the Museum, St. Thomas's Hospital, Surgeon to the Great Northern Central Hospital, the National Hospital for Paralysis and Epilepsy, and National Orthopædic Hospital, and afterwards Consulting Surgeon. He also filled the offices of President of the Medical Society of London and of the Harveian Society, and Vice-President of the Pathological Society. Mr. Adams was the author of many valuable works.

The death is announced of the distinguished Russian geographer General Alexis de Zillo, for more than twenty years an active member of the Russian Imperial Geographical Society, and a correspondent of the Paris Academy of Sciences. In a recent number of the *Izvestia* of the Russian Geographical Society there is an interesting article by the deceased general, in which he deals with the meteorological observations made in the Lukchun depression of Central Asia, which is believed to be quite 17 mètres below sea-level. The yearly amplitudes of the barometer are greater there than anywhere else on the earth.

The secretary of the Trinity House has, by the desire of the Elder Brethren, replied to some statements which have been made as to the supposed slowness with which the Trinity House moved in the matter of wireless telegraphy. The experiment, he says, at the South Foreland commenced at Christmas 1898. The Board afforded the necessary accommodation to the Wireless Telegraph Company free of charge, and aided and encouraged them in every way, being from the outset favourably impressed by the advantages of the system. The Elder Brethren have, however, good ground for stating that the alleged facts as to the saving of property of the value of £52,000 by means of this particular connection are incorrect; and, while they are of opinion that electrical communication with light-vessels might, in certain circumstances, be the means of saving both life and property, they do not consider that any property which would otherwise have been lost has been so far saved through the agency of electrical communication of any description with light-vessels on the coast of England. It is further pointed out that the expense of the permanent adoption of the system would be considerable, and that is not altogether within the control of the Board as the general lighthouse authority.

The Right Hon. W. H. Long, M.P., President of the Board of Agriculture, has appointed a departmental committee to inquire and report as to what regulations, if any, may with advantage be made by the Board of Agriculture under section 4 of the Sale of Food and Drugs Act, 1899, for determining what deficiency in any of the normal constituents of genuine milk or cream, or what addition of extraneous matter or proportion of water, in any sample of milk (including condensed milk) or cream shall, for the purposes of the Sale of Food and Drugs Acts, 1875 to 1899, raise a presumption, until the contrary is proved, that the milk or cream is not genuine. The difficulty of dealing with the above-mentioned branch of the subject of adulteration is well known, and inspectors find it almost impossible in some places to obtain samples of new milk. They are generally told that it is separated milk, or is not sold as pure milk.

A distinguished and influential deputation waited on the Duke of Devonshire and Mr. Ritchie on Monday, to urge the desirability of retaining the Frank Buckland Museum at South Kensington, to be placed under the Board of Trade, so as to add to its usefulness in helping fish culture in the United Kingdom. The Duke of Devonshire made a long and sympathetic reply, but concluded that although it was possible to give a home to this Museum in the new buildings to be erected at South Kensington, he doubted much whether that was a place where they could be shown to the very best advantage. Mr. Ritchie said he agreed that this question was of the greatest importance to the whole community. The Board of Trade was responsible for everything connected with the fishing industry; and if, after inquiry, the work should be intrusted to them they would be very glad to undertake it, and they would do all in their power to further the views of the Deputation. It was quite clear that the Museum at present was comparatively worthless for the purpose for which it ought to exist, and it would be better to abolish it altogether than not to do something to improve it. He hoped that their inquiries would lead to results which would be satisfactory to the Deputation.

It is stated that the whole coast of New South Wales is suitable for the cultivation of the oyster, and it is suggested that a method might be devised of bringing over the oysters (minus the shells), preserved in hermetically sealed vessels. Most people—amongst epicures, at least—prefer oysters freshly opened, and it is doubtful whether it would pay to bring them over in the shell.

Very little has been heard of late years in connection with the Colorado Beetle, which at one time created some alarm in this country when a few specimens were found in cargo arriving from America. It appears from an announcement made by Mr. C. E. Mead in a recent number of the *American Naturalist* that in New Mexico a beetle of the genus Collops has been observed feeding on the larva of the Colorado Beetle. It is known that the crops of potatoes in the district are not much affected by the Colorado Beetle, and if the observation is proved steps will no doubt be taken to transport specimens of Collops to other districts.

The new East River bridge connecting Manhattan Island and Long Island is a short distance above the Brooklyn bridge, and will be the longest, and considerably the largest, suspension bridge. Although it will be only a few feet longer than the Brooklyn bridge, the main span being 1,600ft., the roadway will have a full width of 118ft., accommodating two sets of rails for steam locomotives, four trolley tracks, two roadways, and two sidewalks for pedestrians. The cables will be four in number, each consisting of 37 strands of No. 8 steel wire, each containing 281 wires. A cable will thus have 10,397 wires, the interstices between them being filled with an anti-oxidation preparation.

The owners of autocars, automobiles, and other vehicles using the light hydrocarbons for the explosive medium in their engines, are threatened with a serious difficulty, as it is stated that the railway companies are refusing to convey "petrol" except at the sender's or receiver's risk, which means that the consignor or consignee will have to be responsible for any damage done, no matter how it occurs. There is here an opportunity for an inventor to devise some vessel in which petrol, gasoline, &c., can be carried with the least risk.

Amongst improvements in military rifles, it may be noted that a new Mauser was patented last year in which the loading is entirely automatic. With the ordinary magazine rifle, after every shot the firer has to open and close the breech, during which operation the spent case is ejected and a fresh cartridge transferred from the magazine to the powder chamber. With the new Mauser, all the marksman has to do is to keep his magazine charged. After firing, the breech is automatically opened, the spent case ejected, a fresh cartridge inserted, the striker cocked, and the breech closed ready for firing, these operations requiring only the fraction of a second.

A patent has been recently completed for what is believed to be an important series of alloys containing vanadium. The patent No. is 1694, 1899, H. H. Grenfell. Iron, steel, copper, and other metals are alloyed with vanadium and sodium, the latter being used probably for its purifying effect. According to the invention, both sodium and vanadium are added to the molten metal, either simultaneously or separately, in the metallic state, or as salts; or ferro-sodium and ferro-vanadium, or an alloy of these may be employed. It is stated that the process is adapted to be worked on a large scale, and that, in consequence of the purifying properties of the sodium, it is not necessary that the iron should be in a very pure condition before the vanadium is added.

It is stated that the "Prizes of Honour" which the commissioners of the Swedish Nobel "Million Fund" have at their disposal are to be allotted for the first time this year. The late Herr Nobel desired that the prizes should be given for some work of eminent social or scientific importance produced "during the past year." But, with the approval of Nobel's heirs, a slight change has been made in the limit of time, and the prizes are to be allotted to works of "the last few years." Five of the persons who are to receive the first prizes have already been named: (1) for eminent scientific discoverers, Prof. Röntgen, Sig. Marconi, and Prof. Nordenskjöld; (2) for eminent social work, Henri Durrant, the founder of "The Red Cross," and Frederick Bajer, of "The League of Peace."

USEFUL AND SCIENTIFIC NOTES.

The Practical Electrician's Pocketbook for 1900, edited by H. T. Crewe, M.I.Mech.E. (London: S. Rentell and Co., Limited), is a very useful work for all who have anything to do with electrical machines, and the power employed to drive them.

The following figures represent the amount of water supplied per head per day by the various metropolitan water companies during October last:—Chelsea, 44·74; East London, 29·98; Grand Junction, 47·08; Kent, 30·51; Lambeth, 35·43; New River, 30·88; Southwark and Vauxhall, 37·88; and West Middlesex, 33·41. The average daily supply of water delivered to the metropolis from the Thames during October was 124,622,505gal.; from the Lea, 35,439,164gal.; from springs and wells, 45,333,485gal.; from ponds at Hampstead and Highgate, 635gal. The daily total was, therefore, 205,395,839gal., for a population estimated at 6,003,271, representing a daily consumption per head of 34·21gal.

Power for a Great Exhibition.—No less than 20,000H.P. of machinery will be required for the Paris Exhibition. As it is intended that process of manufacture shall be displayed side by side with exhibits of raw material, much machinery will be distributed throughout the Champ de Mars, and the transmission of energy will be electrical. About 5,000H.P. will (says *Engineering*) be needed for this purpose, besides 15,000H.P. for lighting, making a total of 20,000H.P. The steam-producing plant will be collected in two buildings placed parallel to the old Machinery Hall. Of course, in each case the generators supplying steam will constitute exhibits, and payment will be made for the steam supplied, with an allowance towards the cost of installation. The coal supply will be taken through underground passage.

An artificial stone made in Belgium has been tested in the Malines Arsenal. It is said to have four times the resistive force of French freestone, is insensible to the action of cold, absorbs only 6 to 7 per cent. of water, even after a long dry spell, and cannot be crushed under a pressure of 40 kilos. to the square centimètre. This artificial stone is manufactured in the following manner:—Eighty parts of extremely clean and dry coarse sand are mixed with 20 parts of hydraulic lime reduced to a fine dry dust; this mixture is put into an iron box, which is plunged into a boiler of water, and this is hermetically closed. During 72 hours the cooking goes on under a pressure of six atmospheres, the temperature being maintained at 165°. At the end of this time the iron box contains a perfect homogeneous mass of stone, which rapidly hardens upon exposure to the air.

LETTERS TO THE EDITOR

[*We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible.*]

All communications should be addressed to the EDITOR *of the* ENGLISH MECHANIC, *332, Strand, W.C.*

*** *In order to facilitate reference, Correspondents, when speaking of any letter previously inserted, will oblige by mentioning the number of the Letter, as well as the page on which it appears.*

"I would have everyone write what he knows, and as much as he knows, but no more; and that not in this only, but in all other subjects: For such a person may have some particular knowledge and experience of the nature of such a person or such a fountain, that as to other things, knows no more than what everybody does, and yet, to keep a clutter with this little pittance of his, will undertake to write the whole body of physicks; a vice from whence great inconveniences derive their original."
—*Montaigne's Essays.*

THE PHYSICAL CONDITION OF MARS—SIRIUS IGNORANCE—THE REPORT OF THE DIRECTOR OF THE YERKES OBSERVATORY—PATH OF THE MOON AS REFERRED TO THE SUN—ANIMUM MUTAT—THE TOTAL ECLIPSE OF THE SUN OF MAY 28, 1900—SHORTEST DAY IN TRINIDAD—ROTUNDITY OF THE EARTH—FINLAY'S COMET; AND THE SOLAR MOTION IN SPACE — POSITION ANGLE OF EQUAL DOUBLE STARS—PRONUNCIATION OF ASTRONOMICAL TERMS — LIQUEFACTION OF AIR — THE ASTRONOMICAL SOCIETY OF WALES — DR. ISAAC ROBERTS'S PHOTOGRAPHS OF STARS, STAR CLUSTERS, AND NEBULÆ — THE CIVIL AND ASTRONOMICAL DAY — APERTURE AND FOCAL LENGTH—LADY FLOATING IN SPACE — HAIDINGER'S BRUSHES—SPANISH STATION FOR VIEWING THE ECLIPSE OF MAY 28.

[43280.]—READING the report of a lecture in Belfast by that very eminent astronomer Sir Robert Ball, last month, I am a little surprised to find him lending the weight of his great authority to Mr. Lowell's craze concerning the artificial nature of the markings seen, or alleged to have been seen, upon the surface of Mars; and looking, at least, not unfavourably upon the hypothesis that the so-called "canals" are the stupendous work of intelligent beings, presumably akin to the human race. Now I venture to say that we have no right to assert, nor any tangible ground for asserting, that life on Mars in any way resembles that upon our own world. *Imprimis*, the mass of Mars can only be something like 0·1073 that of the earth, and the force of gravity must, *ex necessitate*, be to that extent reduced there. One result of this would be, as pointed out by Dr. Johnstone Stoney, F.R.S., in his excellent monograph published three years ago in the *Scientific Transactions* of the Royal Dublin Society, not only that an atmosphere whose constituent elements are as light as those composing our own could not be retained by the planet, but that, in Dr. Stoney's own words: "*it is legitimate to infer that water in which* $\rho = 9$, *cannot remain on Mars*"; ρ being the density of a gas as compared with hydrogen. Under these circumstances he expresses his belief that the atmosphere of Mars must consist mainly of nitrogen, argon, and carbon dioxide, and that the latter gas, from its great density, must always remain close to the surface of Mars: "descending into valleys, occupying plains, and pushing its way under the nitrogen, &c." In short, what we describe as the Polar snows of Mars, he regards simply as frozen carbonic acid. If all this be true—and if we admit the kinetic theory of gas, it seems impossible to doubt its validity—what sort of creatures must the "canal" builders be, and whence can they derive the water to fill their "canals" with? This then, I take it, is a case in which suspension of judgment is eminently necessary; and in the light of our existing information (or want of it) to talk of sentient beings constructing canals on Mars is perfectly unwarrantable.

In a familiar passage Carlyle laments that he was not taught the names of the stars in his youth. From the narration of a fact contained in a letter from Ladysmith, which appeared in the *Standard* of the 24th of January, it would seem that the lament of the Chelsea Sage might well be re-echoed by many of the inhabitants of the beleaguered town, for he tells us that: "Night after night, groups of excited civilians watched the Dog Star rise over black Bulwana, and hurried into the streets, declaring that the enemy was signalling to some traitor in the town"! . . . That Sirius should be mistaken for a Boer signalling balloon certainly does show a very painful want of acquaintance on the part of the beseiged population with the very rudiments of a knowledge of the stars. Let us hope that as soon as the Boer republics are incorporated in Her Majesty's dominions, a branch of the British Astronomical Association will be established in Natal to begin with.

The first Annual Report of the Director of the Yerkes Observatory, albeit it does not extend beyond September 30, 1898, has only just reached this country; and very interesting reading it is, containing, as it does, a record of the amount of excellent original work which has been the outcome of the more than princely munificence of Mr. Yerkes, Miss Catherine Bruce, and others. Of course, *the* instrument of this observatory is the mighty 40in. refractor of which so much was expected, and which seems by no means to have belied that expectation. As many who will read these lines will be aware, the dome covering this leviathan instrument is 90ft. in diameter. On two nights in every week Prof. Burnham has devoted his entire time to the measurement of double-stars with this telescope, picking up a few fresh ones in the course of his work. Prof. Barnard has also measured certain double-stars for various purposes. Among others whose distance apart was determined appears κ Pegasi, and this was effected with a power of 3,750, when its components were only 0·1" apart. Mr. Barnard has no difficulty in verifying, with this instrument, the variability of Prof. Pickering's stars in the well-known cluster 5 M. Libræ. He has also fixed the position of 95 stars in this cluster, and of 27 in the even more splendid one, 13 M. Herculis. Furthermore, he has measured the diameters of Mercury and Venus with the giant achromatic, but has utterly failed to perceive the linear markings on those planets which have been imagined by certain other observers. Dickens, in his "Christmas Carol," speaks of poor Bob Cratchit trying to warm himself at the candle, going on to add, though: "in which effort, not being a man of strong imagination, he failed." I rather fear that some of the gentlemen at Flagstaff, Lussinpiccolo, and cognate localities, will be tempted to include Prof. Barnard in the same category as old Scrooge's clerk. Prof. Barnard further used the 40in. telescope to observe Jupiter's Vth Satellite, the Satellite of Neptune, and the position of the now famous planetoid Eros, to say nothing of employing it, and the 12in. one, in numerous observations of the markings on Jupiter and Saturn, measures of the dimensions and position of nebulæ, and the positions of comets. The same indefatigable observer has also obtained a large number of photographs of stars and nebulæ with portrait lenses of various sizes attached to equatorial mountings. By the aid of the great equatoreal, again, and a large solar spectroscope, the Director, Prof. Hale, has succeeded in observing a large number of new bright lines in the spectrum of the solar chromosphere. The green and yellow flutings of carbon were identified, as was the yellow one later on. As the layer of carbon (or hydrocarbon) to which these lines are due is probably less than 1" in thickness, and is in immediate contact with the chromosphere, it is scarcely likely that any instrument materially smaller than the great Yerkes refractor could possibly show these lines. Prof. Hale has further detected bright lines in the spectra of stars of Secchi's fourth type, and has devised a new and larger spectrograph. A very interesting series of experiments has been carried on by Dr. E. F. Nichols, who has been studying stellar-heat radiation, by the aid of a 24in. silvered mirror, into which the rays from Arcturus and Vega were reflected from a large heliostat, and were converged on to the small mica vanes of an exceedingly delicate radiometer. So sensitive was this radiometer, that a deflection of 0·004in. corresponded to the heat that would be received from a candle 15 miles away! were there no loss by reflection or from atmospheric absorption. The mean deflection obtained from 106 measures made on seven nights of the heat radiation from Arcturus gave a deflection of 0·0236in., and from Vega of 0·0106. Hence we apparently receive the same amount of heat from Arcturus as we should from a candle six miles off. I think that I have said enough to indicate something of the very valuable work that is being done at Williams Bay; but I may just add that to the equipment of the observatory there is added an instrument shop capable of turning out the most refined optical and physical apparatus, and an optical laboratory in which, at the date of the Report, a 5ft. glass mirror was being ground. Verily the University of Chicago may be proud of its superb observatory, and no less of those who direct and work in it.

In connection with letters 43248 and 43249, on p. 536, I may say that I myself gave a diagram of the concavity of the Moon's path to the Sun (in letter 39472) on p. 500 of your LXIVth Volume, and unless my memory is curiously at fault, had done so in a much earlier one.

I do not quite understand whether Dr. Godfrey (letter 43251, p. 538) contends that no one, to be consistent, should ever change his opinion, or admit that he may formerly have been in error. Whether or no, though, it is perfectly true that *thirty-three years ago* I did, as he says, imagine and allege, that there had been a year 0, and that hence a new century would begin with 1900. I was young and foolish then, and confess that I made a regular blunder, not having gone into the chronological question in the thorough way in which so many years later I have perforce had to do. Presumably my critic would respectfully admire that witness in our Central Criminal Court in London, who, giving evidence about a horse, stated that it was "16ft. high"; a statement, of course, immediately pencilled down on the back of his brief by the opposing counsel. "What," said that counsel, in beginning his cross-examination, "did you say was the height of the horse?" "Why, 16 hands of course," was the reply. "Oh dear no" responded the advocate, "You said 16 *feet*. I took the words down from your own lips." "Did I say 16ft?" rejoined the witness. "Well, if I did, *I'll stick to it!*" Surely here is an example of consistency after Dr. Godfrey's own heart. But, as said the wise man, "He who never made a mistake never made anything."

The quotation by "Meteor" (in letter 43252, on p. 539) from *Whitaker's Almanack* contains one curious mistake at least, if not more; for, *imprimis*, I gravely doubt if the line of central eclipse will cross any part of the Gulf of Mexico at all, and secondly, certainly will not leave the east coast of America anywhere near Charlestown; but at Cape Henry in Chesapeake Bay, some 379 miles to the north-east of it as the crow flies. An expedition to the Southern States of America would be rather a costly matter, whereas the party sent out by the British Astronomical Association to Portugal, Spain, and Algeria will fill the mail steamer chartered as a yacht, and so be able to travel economically. The joint committee of the Royal and Royal Astronomical Societies only propose to despatch observers to the same localities as the B.A.A. does. There is one thing to be said, and that is, that there are so many brilliant and competent astronomers among our American brethren, that the observation of the phenomena of the eclipse may be left entirely in their hands with the utmost safety.

The difficulty of "Trinidad" (query 97464, p. 545) apparently has its origin in his neglect of the equation of time, and tacit assumption that it is real noon by the clock when the sun is on the meridian or due south. Now, on December 22 the sun souths about 12h. 1m. 20s. p.m., but on November 22 does not cross the meridian until 12h. 13m. 48s. by a well-regulated clock. If he will calculate by a formula which I have given more than once in these columns the times of sunrise and sunset—i.e., the hours, minutes, and seconds from *apparent* noon at his station for the two days specified, and then apply the equation of time—he will see how his illusion has arisen.

I cannot give the date of the Act of Parliament for which "Rota" asks (in query 97489) on p. 545, and which was quoted by Mr. Ebenezer Breach of Portsmouth in his letter to Sir John Gorst; but I fail to see the sequitur of "Rota's" assumption that "the rotundity of the earth was known and taught long before any of our statutes were framed." The earlier Acts of Parliament certainly go back to the XIIIth century or sooner, and the Reformation was not completed in England until 1532. Does "Rota" know that Galileo's works teaching the Copernican system were not finally removed from the Index Expurgatorius of the Romish Church until 1835? I may add that I took the word "statute" from the paper in which the notice of Mr. Breach's action appeared, but for aught I know, he may have relied on Canon Law; and is "Rota" aware that mediævally the "round" meant a *circular* and not a spherical world?

Whence, may I ask, did "Efe" (query 97510, p. 545) learn that Finlay's comet is now visible? I make this inquiry because, up to the time of writing this, I have not heard a syllable about its rediscovery. Under any circumstances the question is an almost meaningless one, because it fails to specify whether it signifies the same orbit or whether it means, Is the comet in the same part of the sky, or in the same constellation (or constellations) as it was in May and June, 1893? At any rate, until the comet actually reappears, the query must be unanswerable in any form. With reference to the rest of "Efe's" question, he may take it that the motion of the Solar System in space has *not* been the cause of the disappearance of comets that used to be periodic. Some, like Biela's, may have broken up and been dispersed, and others perturbed to an extent which has carried them into fresh orbits with major axes so long as to render them practically parabolic. As for the number of miles that the Sun and his attendant planets move through in space in a year, there are 31,558,149 mean time seconds in a sidereal year, and the probable rate of Solar motion lies between 10·6 miles and 16 miles a second. "Efe" can now do a multiplication sum. Why should the Solar motion affect the Leonid showers? The entire system moves as a whole, the ring of Leonids and all. If "Efe" is sitting in a railway carriage and drops his glove, it falls on identically the same spot beneath his hand on the floor of that carriage, whether the train is standing still at a station or travelling at the rate of 60 miles an hour.

In reply to query 97519 (p. 546), I am not quite sure that I ever confronted the difficulty concerning which "Antares" puts it. "γ Virginis," though, did, I seem to remember, once bother me in days gone by; but I surmounted it in that case by looking up the last authentic measures. Had I, however, to measure *de novo* a pair of sensibly equal stars, I should take the *preceding* one as my initial point.

In connection with query 97521 (p. 546), I remember giving, some time ago, in these columns the pronunciation of the names of a considerable number of the fixed stars; and, if I remember rightly, some brother correspondent gave a more elaborate and exhaustive list than mine. For these "N." may, if it is worth his while, search the indices. "Mare" is pronounced Mair-ee, and the Greek letters Al'pha, Be'ta, Gam'ma, Del'ta, Epsi'lon, and so on, just as they would be in learning the alphabet.

It has been pointed out to me by a scientific friend that my reply to "Mark," in the third paragraph of my letter (43244), on p. 534, is of too unqualified a character, conveying as it does the impression that liquefaction of the lunar atmosphere could under no circumstances occur without stupendous pressure. Merely as a matter of course I meant at any temperature which we are justified in assuming to have existed on the moon. Given a sufficiently low one, and our terrestrial atmosphere would liquefy without any extraneous pressure at all; but we have no reason to suppose that, even now, the temperatures of the lunar surface approaches that at which a mixture of nitrogen and oxygen would be reduced to a fluid state, and *à fortiori*, at the time during which the moon was passing through an actively volcanic stage, it must have been very much higher. And, by the way, whence would "Mark" get his winds after the atmosphere of the moon was solidified? If he can obtain the perusal of the latest edition of Deschanel's "Natural Philosophy," translated by Everett, and published by Blackie and Co., he will find much that is instructive with reference to the liquefaction of gases, critical temperature, and the like.

I have just received the current part of the *Cambrian Natural Observer*, the quarterly journal of the Astronomical Society of Wales, and am gratified to find that the membership of the society has increased from 75 to 90, or between 8 and 9 per cent. Verily what Virgil said of rumour may well be applied to this excellent little association: "Viresque acquirit eundo." The number itself is largely occupied with records of the observation of the Lunar Eclipse of Dec. 16, which did occur, and of attempts to observe the more or less expected phenomenal shower of Leonids which did not. Among the latter will be found an account of the sensational balloon ascent made by the Rev. J. M. Bacon and his daughter, which was fraught with such danger to the aëronauts. I am amused to find the editor congratulating himself that the "C. N. O." "is the only popular scientific periodical that contains no portion of the Twentieth Century unpleasantness."

Every student of the physical structure of the Stellar Universe will welcome the second volume of Dr. Isaac Roberts's classical "Photographs of Stars, Star Clusters, and Nebulæ," which has just issued from the press. It would be difficult to exaggerate the value and importance of this splendid work, the more especially as its gifted author has experimentally discovered that with every conceivable care in the development and fixing of negatives, the images of faint stars fade out of the films after a comparatively few years. In illustration of this he gives two instances; one of a plate on which, soon after it was taken in February, 1886, he counted 403 star-images on the negative, whereof in May, 1895, only 272 remained; and the second of a negative of the same region taken in March, 1886, on which 364 star-images appeared, but upon which, on re-examination in May, 1895, only 234 were left. Now one purpose of capital importance which such photographs are taken to serve is that of presenting an irrefragable facsimile of the region depicted at the given date for comparison with others made at future and distant ones, by which any actual objective changes in the heavens would be instantly rendered apparent. If, however, details disappear after the fashion indicated by Dr. Roberts, it is abundantly evident that the negatives must in future ages become simply valueless; and hence the policy and necessity of obtaining positive copies of them in indestructible printing-ink as adopted in this beautiful volume. It is one which scarcely admits of description. It must be seen and studied for its beauty and value to be estimated. The student approaching the subject for the first time may well be struck with amazement at the intricacy of structure shown in the spiral nebulæ which occupy a considerable share of the volume, as also with the arrangement of groups of stars in so perfectly definite a form as certainly to indicate a direct physical connection between them. For Dr. Roberts's views on the genesis and evolution of suns and systems, and explanation of the probable origin of those temporary stars, or Novæ, which from time to time have blazed out in the sky, the reader must go to his book itself. I would fain hope that anyone who does so will thank me for having directed his attention to so interesting and important a work. I hear, on what I believe to be good authority, that only a limited number of copies of it have been printed. If this be true, the sooner the student obtains it the better.

In connection with letter 43262 (p. 554), I should like to say that the latest *Nautical Almanac* in my possession is that for 1902, but that I certainly should have heard of any intended alteration in the assumed beginning of the day in that for 1904, had it been in contemplation. The *Annuaire* of the Bureau des Longitudes is not the equivalent of our *Nautical Almanac*. The French analogue of that is the *Connaissance des Temps*. The practical astronomical day begins when the true sun's centre is on the meridian —a perfectly definite and easily-observable phenomenon, which cannot be predicated of midnight. It would be impossible for astronomers to adopt the senseless division of the day into two periods of twelve hours each. It would, in many cases, produce the wildest confusion. I may perhaps add that I see from your "Answers to Correspondents" on p. 565 that your computer took his first minimum of Algol from 'The Companion to the Observatory' for the current year. I now notice from the February part of *The Observatory* that it, in turn, was led into error by the *Annuaire* of the Bureau des Longitudes (which is of course intended for popular reading), having given its Ephemerides for 1900 in civil time. Undoubtedly this was the origin of the *Times* paragraph, which, equally as a matter of course, was blindly copied into all sorts of other papers, even (so-called) scientific ones. No alteration has been, or is likely to be, made in the *Connaissance des Temps*.

"A. S. L." (letter 43267, p. 556) is perfectly correct in his assumption that there is no *optical* reason for the 14 or 15-to-1 proportion between the aperture of a refractor and its focal length. It is simply a matter of practical detail and application of experience. With him I have always thought that instruments of short focus give more brilliant images than long-focussed ones; but they involve much sharper curves in the lenses, and after a certain point has been reached the word "achromatic" as applied to them becomes a mere euphemism.

It might interest Mr. Wadsworth (reply 96919, p. 559) to turn back to pp. 34 and 35 of your LXIVth volume.

"E. H. R." (query 97538, p. 564) may read p. 90 of Spottiswoode's "Polarisation of Light," in Macmillan's "Nature Series," with profit. It is impossible to improve on the description of Haidinger's Brushes and the method of seeing them given there.

In reply to "Corona," the eclipse of May 28 next will not be visible as *a total one* from any port to the West of Spain. Alicante and Cape Santa Pola, in the Mediterranean, will be the only Spanish stations on the coast whence it can be so seen. Over, on the Portuguese coast, would seem to be the likeliest place for your correspondent.

A Fellow of the Royal Astronomical Society.

VARIABLE STAR OBSERVATIONS, JANUARY, 1900.

[43281.]—R AURIGÆ was very faint during the last three months of 1899. Most of this time it was below 13·0 magnitude and beyond the reach of the Rousdon telescope. A rise has now set in, and it was observed 13·1 magnitude January 5, and by the end of the month had increased to about 11·5 magnitude.

R Lyncis passed a minimum, 13·0 magnitude, January 10, when it was a very minute faint point just seen with power 132. The interval since the previous minimum, January 16, 1899, was 359 days. On January 30 it was 12·2 magnitude.

T Ursæ Majoris. Owing to unfavourable weather the minima could not be well observed; but from an inspection of the light-curve it may be assumed at 13·0 magnitude November 15, 1899. The interval since the previous minimum, March 16, was 245 days. This variable is now on the rise, and will soon become a conspicuous object.

S Boötis passed a minimum, 13·0 magnitude, November 20, 1899. The interval since the previous minimum, February 1, is 292 days. A steady rise is now in progress, and 9·2 magnitude was reached January 27.

R Cygni has been below 13·0 magnitude, and invisible with the Rousdon telescope for nearly five months; at times a very faint nebula has been seen in its place. On January 24 the variable had reappeared as a minute but well-defined point 12·7 magnitude.

The instrument in use was the 6·4in. equatorial refractor by Merz. Weather was fairly favourable, and observations were made on 14 nights, some of which were remarkably clear. **C. E. Peek.**

Rousdon Observatory, Lyme Regis.

MINIMA OF ALGOL.

[43282.]—AT the risk of appearing needlessly hypercritical, I venture to suggest that the directions given on p. 553 (viz., to subtract 12 hours from the several times given on pages 439 and 527 as Minima for Algol) scarcely meet the requirements of the case, at least so far as the generality of your readers are concerned. In almost every instance this would only give the daylight occurrences of this phenomenon, when, of course, they would be invisible, and, therefore, not usually recorded, and would leave out altogether any mention of those for which the lists are specially designed, but, of which, being supposed to occur in daylight, all record was omitted. Of course January being now past and over, no useful purpose would have been served by giving a fresh list for that month; but this would not have been the case with February, wherein all the visible occurrences are still future (but with one exception not mentioned in the list given on p. 527), and for which a revised list, similar to that contained in my previous letter, would, I think, have been found useful. **W. T. N.**

LUNAR SEAS AND RAYS.

[43283.]—I HAVE just read "F.R.A.S.'s" remarks in 43189. I think I have not misrepresented Mr. Tepper's suggestion—it is scarcely right to call them his *views*; but he wished the idea to be discussed.

I am not anxious to sustain the meteoric theory; but I think it is an important factor which should not be forgotten in any effort to understand the causes of the lunar formations. Mr. L. B. Tappenden introduced it in Dec. *Knowledge*, and hence my reference to it. But neither Mr. Tappenden nor myself is the originator of this view. Mr. Gilbert held views much like it in 1892, and Mr. Proctor before then. "F.R.A.S." says it is obvious I have not read Prof. Darwin's work on "The Tides." I have seen his large mathematical treatise; but I could not wade through it if I would, and, I had almost said, would not if I could; it would be too much work for a lazy man. But I have read his popular book, "The Tides," and though he states that both earth and moon did rotate more rapidly than now, I still think it impossible that the moon ever could have rotated faster than it revolved in its orbit if it was ever attached to the earth, and separated from it by such means as Mr. Darwin suggests; but my views on this point will not be presented now.

"F.R.A.S." asks many questions. I will answer as concisely as possible.

1. Has he reflected . . . . on the size of those formations?—*Yes*. Is he aware that the diameter of Copernicus, Tycho, and Kepler are 56, 54, and 21 miles across.—*Yes*.

2. What sort of a meteorite and of what size to make a hole 56 miles in diameter?—*I should expect such a one as falls on the earth*, specimens of which exist in the museums of London and Paris. The size required would depend on the nature of the surface on which it fell, and the mass and velocity of the meteor. "It seems impossible that your correspondent can ever have examined those formations with adequate optical power."—My own telescope is only a 3in. achromatic, but I have had the use of others which are larger as often as I found more power needful. A 4in. Wray, and the 6in. by Cooke in the observatory, besides reflectors by Browning 10in., and by Turnbull 12in. If the work is bad it is in the observer, not in the instruments.

But I have not been a careless observer, and I have made drawings and paintings from the telescope many years ago which exist still, and a comparison of these with the fine photos. of the Brothers Henry, and the Lick and Paris atlases shows them too good for eye drawings. But it is to the great photographic work of the Lick, Paris, and other observatories to which we turn for light on the lunar surface, which, added to work of Rutherford and Draper will help us to solve the question of lunar seas and rays. I have not advanced any views of lunar cosmogony in my letters. My object was to get Mr. Tepper's suggestion discussed in "our" paper. I hope this will be done, and I thank "W. R. P." (43192) and "F.R.A.S." for calling attention to it.

Toronto, Jan. 24. **A. Elvins.**

THE ZODIACAL LIGHT—PHOTO OF RAINBOW.

[43284.]—THE night of Sunday, Jan. 28, being the first clear night for some time, I went out to look for the Zodiacal Light, and at once perceived it. It was a long thin cone, in whose base Venus was brightly shining, reaching up through Pisces to a little south of γ Arietis, beyond which I could not trace its blunt apex. It seemed to me to decidedly dim the fainter stars of Pisces over which it passed. Time, about two hours after sunset.

Some time ago "F.R.A.S." mentioned the difficulty of photographing meteoric phenomena. I inclose an ordinary sunspot of a rainbow, which is, however, too faint, I am afraid, for reproduction. It was "snapped" on a Sandell "Perfect" plate last September in an ordinary Kodak.

The brightness of the portion of sky within the

bow is well shown in comparison to the sky outside, as it ought to be by theory. On the negative the supernumerary bows may be just made out.

Galway. M. B.

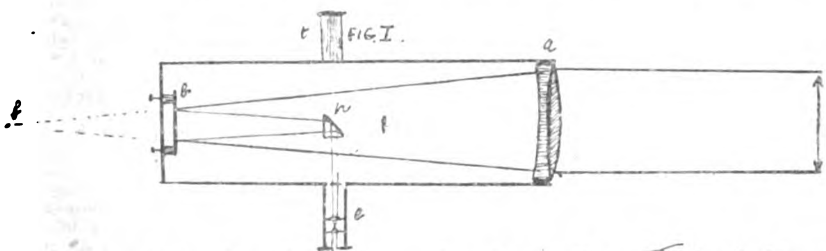
TWO NEW FORMS OF TELESCOPES.

[43285.]—I BEG to lay before you my idea for two new forms of telescopes, which I think present some advantages. One objection to the construction and use of large refractors is, of course, since focal length is a consideration, the vast amount of material and labour necessary to produce tubes long, and at the same time rigid, enough for the reception of the glasses. Again, to those who use both the reflector and the refractor to any large extent, it becomes evident that, although the reflector cannot compare with the refractor as regards illuminating power, yet the ease with which it can be used in almost any position (I am speaking more especially of the Newtonian and such like forms), and its portability and compactness are such as to commend it to many.

Now my idea is to combine the refractor with parts of the reflector in such a way as to make an instrument differing very little in appearance, size, and compactness from an ordinary reflecting telescope, and at the same time possessing all those desirable qualities which are so well known as appertaining to a refractor. I have called this form a combined refracting and reflecting telescope. Such an arrangement would be, of course, suitable for refractors of moderate and large dimensions, and having a considerable focal length, and by the very simple arrangement I shall mention, the tube length would be reduced *by more than one half.*

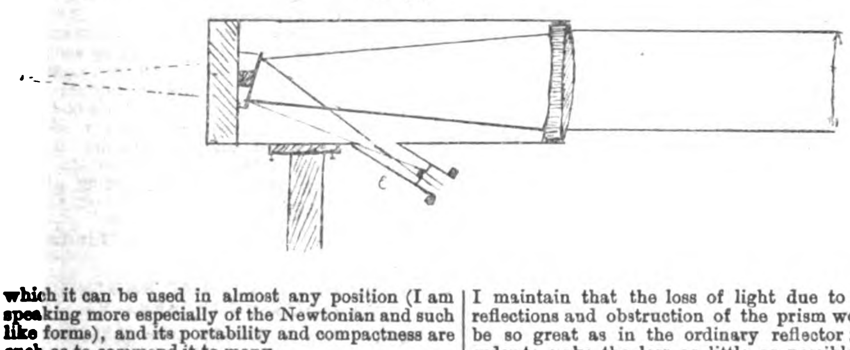
A reference to the accompanying diagram I will explain the arrangement. Fig. I. represents the telescope arranged in the Newtonian manner. About half way between the o.g. (*a*) and the focus (*f*) in the cone of rays is placed a *plane mirror* (*b*) which reflects back the rays until they fall on a total-reflection prism (*p*) which again diverts them, this time at right angles to the tube, into the eyepiece-tube (*e*). As in the Newtonian reflecting telescope, the eyepiece-tube may be one of the trunnions (*t*, *t*) on which the tube can revolve in altitude, and therefore the eye would not require to be moved at all. Shortly, the advantages would be these:—

1. Great reduction in tube length. 2. The definition of a refractor combined with the compactness, &c., of a reflector. 3. No air currents in tube.



a = o.g.; b = plane mirror; e = eyepiece-tube; f = foc. of o.g.; p = prism
t = trunnions.

FIG. II.



I maintain that the loss of light due to the two reflections and obstruction of the prism would not be so great as in the ordinary reflector; but in order to make the loss as little as possible, I have adapted the form shown in Fig. 2, or Herschelian. In this form the small mirror is tilted so as to reflect the rays into the eyepiece-tube (*e*) placed at an angle to the body-tube.

In the diagrams Fig. I. is a plan, and Fig. II. an elevation.

I shall be glad to see criticisms and opinions on the subject from some of your very able contributors and fellow-amateurs.

Alpe-street, Ipswich. Henry A. Bromley.

TELESCOPES AND MICROMETERS.

[43286.]—HERSCHEL, in describing in "The Telescope" the proposed construction of a Gregorian with the two mirrors silvered at the back, ends somewhat disappointingly. Having discussed the conditions of the problem, he merely says that Airy's calculations showed such a construction was possible, but gives no example. The main difficulty appears to be the correction of both the spherical and chromatic aberration by making both reflectors of the same kind of glass.

Is there any theoretical or practical objection to making the large mirror of crown and the small one of flint glass, so as to thereby destroy the chromatic aberration, and thus leave merely the spherical aberration to be corrected by the curves employed? The possibility of protecting the silvered surfaces would be considerable again; but perhaps the difficulties of construction and the excessive cost of optically pure glass (which would be a necessity) may more than balance this advantage. Has such a telescope ever been actually made? Lacaille, in his "Traité d'Optique," throws doubt on the accuracy of micrometrical (telescopic) measurements, on account of the image being curved, and thus not coinciding with the plane of the (filar) micrometer. If this is correct, what becomes of the decimals of a second that are to be seen in published measurements? What says "F.R.A.S."?

A. S. L.

IS THE UNIVERSE INFINITE?

[43287.]—MR. BURNS is no doubt quite justified in his contention as regards the number of stars, on two suppositions. (1) That the dark stars (dark bodies in space) bear no larger proportion to the bright ones at remote distances than at near ones; and (2) that there is no other medium in space which absorbs light. I might perhaps add (3) that the ether extends to infinity; for I do not see how light could reach us from a place where there was no ether. On these assumptions, the number of stars is not merely finite; but, if I may employ the term, moderate. Not so large, for example, as the number of animated beings at present on the earth.

The effect of an absorbent medium, whether composed of small opaque bodies or not, would probably resemble that of a haze, which, though its effects are imperceptible as regards objects close at hand, completely obliterates a distant mountain range. Such a haze would make an infinite universe appear to be finite to the beholder, even though the components were self-luminous.

W. H. S. Monck.

IS THE THEORY OF GRAVITATION A FINALITY?

[43288.]—MR. ALEXANDER (in letter 43260) asks the question: "Is the theory of gravitation a full and final explanation of the mechanical and physical cause of the known movements of the Solar System?" The answer is: "No; it does not profess to be so." Gravity explains the *restraint* which is put upon the motion of the planets by the attraction of the sun; but it does not explain the motion, or, rather, the cause of motion. A mechanical explanation may be given of the action of the reins upon the bit and mouth of a driven horse, and perhaps of the consequent change in the horse's direction of progression; but a similar explanation cannot be given of the cause which produces the trotting or galloping of the horse, and of the consequent motion of the carriage attached. The attraction of gravity prevents the planetary motion from being other than it is—*attraction*, whether the planet is receding from or approaching to the sun; but gravity does not profess for one moment to explain the cause of motion. "There is no defect in the theory of gravitation because it cannot explain what it does not profess to explain."

That is an answer to the *second* question in letter 43266, and the answer to the *third* is: "Yes; plenty of new facts have come to light since the first statement of the theory of gravity; but none of them suffices to explain the cause of motion. It remains for future generations to discover it."

Peasmarsh. F. B. Allison.

MOTOR-CARS.

[43289.]—KNOWING personally the responsible position the writer of the articles has held in the motor industry, I have the greatest respect for his designs, and although he states that a car has not been made from the designs now appearing, the readers may have every confidence in following his instructions. *Re* the horizontal valves, cheapness of manufacture is no excuse for placing them in that position. The valve-stem always wears the bottom of the guide, and when the guide-hole gets elongated they depend solely upon the spring to draw them into their seats, and after a time they give trouble. Valve should always work in a vertical plane, and when designing a motor this practice should never be departed from, however tempting the horizontal valve may appear.

I am glad to see the motor has a water-jacket.

Too many people are just now spending or wasting a lot of time and money in trying to make a small air-cooled motor drive a car satisfactorily. Keeping the motor at a proper working temperature is much more important than many people think; but I think the writer will agree with me that people owning water-cooled motors find more trouble with the joints going and flooding the cylinder than any other complaint.

However much the writer may say to the contrary, no matter how good the workmanship, or of what material they are made, they occasionally want remaking, and this is not a pleasant job. I have found a layer of tinfoil or lead paper next the water-face last as long as anything; but even these go sooner or later, and they manage to leak in the most provoking manner just when you are many miles from nowhere on a dark cold night. I think that very important item should have been avoided; it easily can, the cylinder not costing more than the one described.

I am pleased he is describing a carburettor of the surfacing type, as this class of vaporiser is simple; if properly managed, is reliable; and can be made by anyone for a few shillings. Besides, they leave less smell than those of the spray variety, and will run a motor any speed up to 2,000 revs. per min.

Yes, jockey pulleys and belt transmission are cheap, simple, and reliable in dry weather; but unless some means are taken to protect the belts in wet weather from the mud, the driver will have trouble, and plenty of it; the jockey may be tightened to breaking point, and then the belts will persist in slipping. As to fitting governors, what is the good of advancing the ignition to gain revs. on the engine if the governors cut out at the normal speed? The sole secret of success of electric ignition on small cars is being able to alter the speed of the car by altering the revs. of the engine; this being done by advancing or retarding the ignition. I take it the governors are to be fitted to prevent the engine racing when the work is taken off. The engine can be stopped from racing without governors by connecting the handle of the advance ignition to the pedal of the brake, which takes off the jockey pulley at the same time. By this pedal the engine could be slowed down simultaneously with the stopping of the car.

Lowestoft. **W. L. Adams.**

MOTOR TRICYCLES.

[43290.]—IN reply to Mr. Russell (letter 43274), perhaps he did not clearly understand my description, though I made it very plain. The gist of the whole thing is the engine's flywheels run in *opposite* directions. To do this you must use an intermediate pinion. This prevents the explosive impulses from synchronising; when they do, vibration is the result.

The engines must be on either side of axle to get the best effect. I mentioned about even number of teeth to prevent amateurs from using an odd number on intermediate pinion. To run engines as you suggest is quite useless as regards balancing. Dividing it into two or more cylinders gives you a less initial shock, but will not reduce vibration much. You must have an interesting sample of motor tricycle from your description of it, and I should judge you have many pleasant recreative hours by the road side, which no doubt tends to make you of a thoughtful and sceptical turn of mind. However, there is not any difficulty about running them, though chief fault is noisy gear, which also causes loss of power, as gear-wheels soon get worn and run badly. Why some motor-tricycle maker has not adopted multi-thread worm and worm-wheel driving is what I cannot understand; seeing how well and silently it runs on some of the new electric cars. A 7 or 8 to 1 ratio can easily be made and motor could be secured to small coupling on worm shaft to prevent ever disturbing worm. I merely offer this as a suggestion. If any one has a better method shall be glad to hear of it, as I am always open to receive any information. I think if some of our readers would send *small* rough outline sketches of frame for small cars it would do much to hasten what is needed by the public—viz., a small two-seated car to take two side by side not exceeding 3ft. 6in. wide in any part to go through about same space as tricycle, the seating of which could be arranged to overhang the wheels to get comfortable width, and motor I think should be secured to a separate frame from which the seating is, with good springs between. Speed is not so important as reliability and freedom from breakdown and motor shedding parts of its bowels by the wayside. It must be designed for *bad weather*—not merely for conditions of sunshine and dry roads, and should most certainly have a two-speed gear. Above all, it is a *sine quâ non*, that it is fairly cheap to be within the reach of persons of moderate means. This is the class of motor vehicle that will take on and pay well too. Who will be the first to make it remains to be seen. **Monty.**

STEAM-ENGINE.

[43291.]—I SHOULD like to endorse E. W. Fraser's remarks on steam-engines for amateurs and small power users. I made myself a steam-engine, cylinder 2¾in. diam., 5½in. stroke, and find it drives a 6in. lathe well. But it takes me three-quarters of an hour to get steam up, and that is not much catch, say to drill four holes. My injector is always failing, and it is by a first-class firm. Then you have to stop for steam, or oiling the engine, or stoking, and the result is you waste half your time, and do your job in pieces, and do not improve the finish of it. I am now making myself a gas-engine, and shall be very glad when it is done. **C. Wade.**

[43292.]—MY own experience with gas-engines is somewhat different to E. W. Fraser's. A steam-engine at least runs evenly, and it will go when steam is turned on. I have never had any trouble in keeping up the pressure, always providing that the boiler is large enough. A boiler that is too small for the engine wants constant attention. A steam-engine is less liable to go wrong, and requires less fiddling with than any gas or oil-engine I have yet met with. The gas-engine seems to be designed to keep one's pocket for ever on the bleed. Some engines burn out iron ignition-tubes at the rate of a dozen a week. Iron tubes may be cheap, but two a day makes the cheapest costly. Alloy tubes last sometimes a few weeks, but they cost a good bit, so that in the end they are no cheaper. The drive of a gas-engine is a succession of jerks more or less violent, according to the make, which causes breakage of small drills and milling cutters. In outlying districts or parts where the gas pressure is weak or varying, there is always the possibility of the tube burner going out suddenly. With a ½H.P. engine driving a 3in. lathe, this is a small matter; but where you have a big engine driving a lot of heavy machinery, it is exceedingly annoying, as all the machines have to be thrown off before the engine can be moved. In the matter of space occupied, a 3H.P. gas-engine is about as bulky as a 6H.P. steam-engine. The cleaning out of a boiler is nothing compared with the cleaning of a gas-engine cylinder, which is the filthiest and dirtiest job conceivable, and the operations connected with it are not calculated either to improve a man's temper or his language. No, a gas-engine is not all lavender, and, in my opinion, is a highly overrated machine. If it would do all that is claimed for it, it would be a most ideal motor; but it does nothing of the kind, and it lets you down badly if you repose the slightest confidence in it. Every engine ought to have a timing valve; but, for the sake of cheapness, they are usually omitted in small motors. The consequence is they waste the gas, and fire too early or too late, according as how the load and the gas pressure varies. Any tinkering about with the flame of ignition-tube only results in a waste of time and language. An oil-engine is a still more bulky machine than the gas-engine—has all its defects and a good many more of its own. **S. B. K.**

[43293.]—WHAT our friend E. W. Fraser (letter 43279) says is perfectly correct, and is not only applicable to such small engines as depicted here, but much larger, and for why, but that the boiler that is constant in its action has yet to be found? Some two years ago I was on the way to show how a constant boiler, and with automatic feed perfectly safe, could be made, when, on the Christmas Eve two years ago, I met with a terrible accident from which I was for a time afraid I should have lost the sight of both eyes, and was compelled to be compulsorily idle, and am in consequence now forced to have lazy spells every now and again, as my eyes will not stand to their work, and that means misery. The above is applicable to large as well as small engines. All want constant attention if you want to get anything out of them, even in an engine where the engine is of 100H.P. and the work constant; as, for instance, a pumping-engine for water-works where the draught from well and lift up a stand-pipe are always constant. Things want looking after sharp to keep things regular; oil, air, and gas the same. The latter—i.e., gas—if properly constructed, can be trusted to take care of itself for hours. If run at its proper speed, you will have no trouble to get what you want; but if throttled or attempted to govern the affair by the charge, i.e., wire-draw it, if you expect anything certain out of it; but in constancy you will be disappointed, that is certain; for small motors, no matter what they are, must be run at their highest capacity, and kept to it, if you want anything out of them, and they will not overrun themselves if properly constructed. The theory laid down as regards steam space and grate surface will not do for these as per scale. A surplus quadruple will not be found equal to the occasion unless you work up to three times the pressure upon your boiler, and reduce the same by a reducing valve between boiler and engine, to keep it constant. I have wondered many times why this has not been done for the pumping engine, as above; it might be and perhaps is done, but it has never come under my notice. The difficulties in my experience do not lie only with small plant as regards feed, and if you refer to the "E. M." for 1897 you will find some lines to get over the difficulty in constant automatic feeds in steam generators not boilers. For these light engines and generators that are perfectly safe at anything from 40lb. up to 200lb. or 300lb. per square inch, slow combustions, that may be left for hours. There has been a great mistake as regards steam generators—i.e., boilers, and so there is now; but things are looking up, and it has been an acknowledged mistake for years, the throttling of engines. But there are many such on the market now, as see query 97440, in the number for Feb. 2, 1900, and see queries *re* gas-engines, from faulty construction, the hundreds that are on the market that are—well, I might say useless. Difficulties and queries are cropping up every week, and they cannot be depended upon unless properly constructed—an independent valve for ignition, gas, air, and exhaust, all positive action by cams, and springs regulated to all requirements. Air-valve the weakest; and why? Because you cannot gauge the reaction after the explosion. As to free action in running for speed, according to the construction, there is a limit to taking in charges and ignition that you cannot get beyond, and they should be allowed to work up to that limit—i.e., small plants.

The time has very nearly come when we shall only have to agitate a pound of water to get a ton of steam with a tenth part of the fuel we have used to agitate a ton of water for a pound of steam. I live in hopes of finishing what I commenced—i.e., the generator and an aërial condenser. I have looked things up, though a series of accidents cropping up one after another has not left me breathing-time scarcely. I gave it up for a bad job; but I am about as tough as they make them, I think, and have pulled together once more, though to-day I felt very much inclined to shut up shop, seeing the blunders I have made recently, and which I never realised until I dreamt about them, and woke up with the words "I never could be such an ass!"—so, between 2 and 3 a.m., I jumped out of bed and hunted up the "E.M.," and, sure enough, my dream was true. It upset me not a trifle. **Jack of All Trades.**

DOUBLE-ENGINE RUNNING ON RAILWAYS.

[43294.]—YOUR correspondent "Large Boiler" (43259) does not seem to realise the fact that large boilers mean large fireboxes, and large fireboxes mean increased coal consumption and increased work for the fireman. The quick transit of heavy engines over the line means quick deterioration of the permanent way, for in double-engine running the weight is scattered over a large space compared to the concentrated weight of a single heavy engine.

Another point to be considered is the fact that the weight of almost all trains fluctuates greatly between the various stopping places. One train may commence its journey very heavy, but at the first stop may be relieved of half that weight, whilst another may start light, but soon become very heavy. In the case of the first example, the auxiliary engine could be detached when no longer necessary, whilst in the second an engine can be attached. I believe if "Large Boiler" goes into the matter he will find but few cases of the second engine completing the through journey.

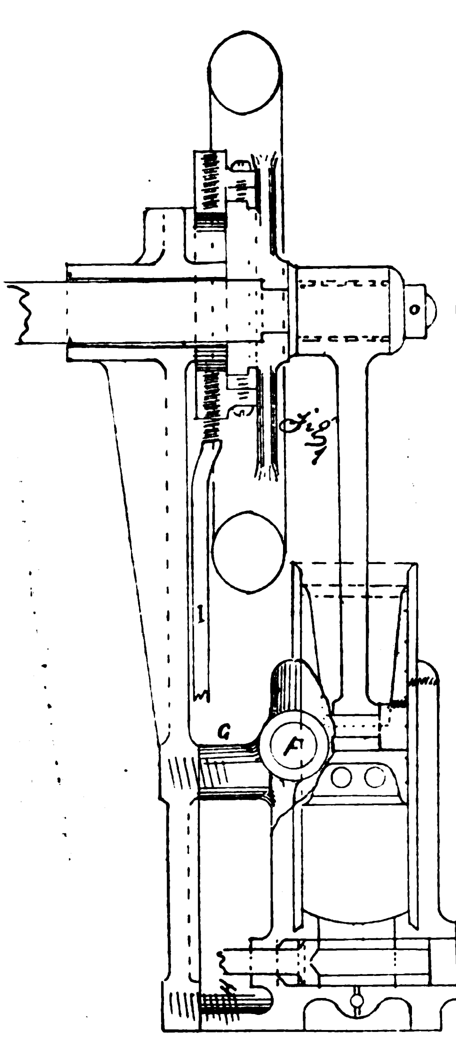
A point both "Large Boiler" and "L. T." (43271) seem to ignore is the weather. An engine can pull over dry rails what is impossible over wet and greasy metals. Thus a train may commence a long run with a fine dry road; but a shower of rain falling in the midst of that journey may delay the train several minutes through wheels of the engine slipping over greasy rails.

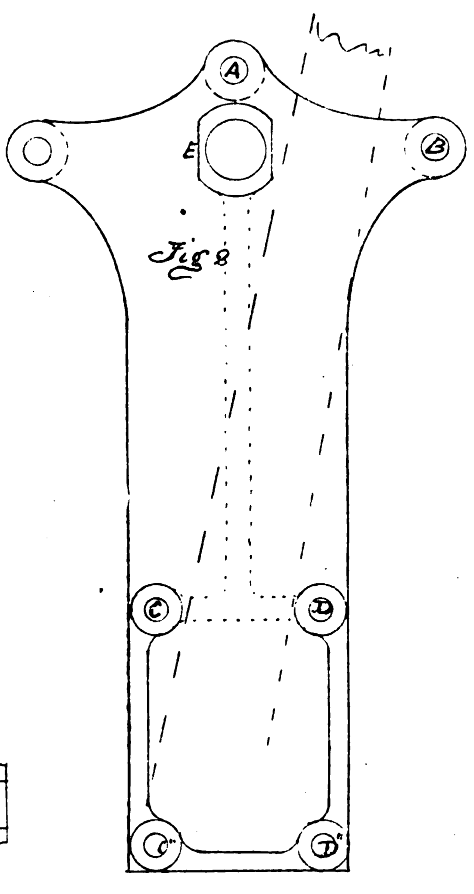
But, when everything is said and done, the chief difficulty lies in the fact that it is almost impossible to foretell the weight of any particular train until all luggage and passengers are on board. It is then far easier to requisition the services of any express engine which may be on hand, than to keep any particular heavy engine waiting for such an emergency. But, granting that heavy engines were used habitually on certain trains, it would be found that whilst on some days the engine would be utilising its full power, on uncertain days a light load would mean a loss of power, in the same manner as in the double-engine running of the present day on trains of a *uniform weight for the through journey*, of which there are few. **Lindum.**

HOW TO BUILD A LIGHT ENGINE FOR VARIOUS PURPOSES.—VI.

[43295.]—THIS is the edge view of the same as appeared in No. V.—i.e., Fig. 1—and, therefore, will not require the explanation that is there. F is shown here one of two lugs that are cast upon the cylinder jacket for the purpose of turning to account the convenience that it may be laid upon either side as a horizontal engine, when it would be policy to make one of these into an outlet for the exhaust to right or left to suit your convenience, and if not wanted, would not be in the way of anything; and drilled out and tapped and studs put in may be utilised for fixing or fixing anything to; but when put upon its side, bored out, as shown, down

to, and including the two chambers for exhaust. G are bosses for carrying the entablature, and from these to the foot is bored in. From there upwards the face is plain that a light sheet brass or iron casing may be riveted on, forming a bore with a sliding front or side to give the engines an extra long lease of life, or an extra chance of doing well. I have put in where possible a loose liner in the shape of a steel bush, perforated, and in applying this, care must be taken that the sharp angles and burrs are taken off with a scraper to make them rounding. At G and H studs may be fixed instead of set-screws—that supposing you were going to fix it to the supporting upright of a tricycle (see Fig. 2, where such is shown), that if A B C D are furnished with studs that pass through saddle-pieces or clamps, you have the means of fixing it to the same, no matter what the angle. Here you will see that there are bosses C D, C′ D. These are slight projections for taking the unnecessary surface off





in fitting the entablature to the cylinder E. This inside boss is filed away on both sides for the gate to slide over that carry the rubbers for the eccentric motion to the valve. Now, when this guide is only the shaft, the motion can be carried around at any point. Now, this is done in this instance that the bearing may be continued up to boss of wheel for shaft, as in a confined space we must take every advantage of getting as much bearing-surface as possible. Some of you will say: Why this motion? Why not have the usual eccentric and strap-levers, &c.? First, it is simple; second, easily fitted, light, no complications, easily adjusted for wear, if any; and last, but not least, direct-acting—no swing of the rod, and no bolts to work loose, and the whole can, as I have said, be boxed up snug.

Jack of All Trades.

As evidence of the tendency towards heavier locomotives and longer trains used on American railways during recent years, some interesting figures have been published regarding the weights of engines turned out by the Brooks Locomotive Works in the years 1891 and 1899. The average weight of the engines built in the former year was 82½ tons, and in the latter 121 tons. The figures are based on an output of 226 and 300 locomotives respectively. The weights given are those of engine and tender in working order.

REPLIES TO QUERIES.

*** *In their answers, Correspondents are respectfully requested to mention, in each instance, the title and number of the query asked.*

[97180.]—**Marine Navigation.**—I am not surprised that "J. H. H." cannot refer me to any work which treats of the subject; but perhaps there may be something in the records of the Institute of Marine Engineers. As to what "Charlton" (p. 559) says about the Davey motor, I remember seeing that in the Inventions Exhibition in 1885. I am also aware that water from condensed steam is used in the boilers; but I am not aware that exhaust-steam from the auxiliaries is used to drive the main engines at four knots. G. S. N.

[97301.]—**To Lanternists (U.Q.)**—I think cylinders are preferable and cheaper in all ways to automatic generators, unless living in very out-of-the-way places. I have used a double band (Ives) saturator, and although this is, by many people, considered about the most dangerous one, have never had an accident, and never failed to get a good light; but, at the same time, you would not save much by using a saturator, and no doubt the best plan, when working where gas is not laid on, is to have two cylinders, one for oxygen and one for coal-gas (not hydrogen); and if you use your two lanterns as a biunial, you are obliged to. All books on the lantern treat of lime-light. Rileys publish some small handbooks.

Optical L.

[97327.]—**Sparking Coil.**—There have been many replies on this subject—sparking coils of all sizes. As to a work on the subject, there are several. Allsop's, perhaps, as good as any. The articles which form that were published in these pages some few years ago. T. W.

[97328.]—**Small Dynamo.**—Mr. Chase will find in back numbers full directions for making all sorts of small dynamos. See the indices of the last six volumes, say, for references. M. D. P.

[97345.]—**Wax Phonograph Records.** — If "Junius" wants to obtain full particulars about the wax used for phonograph records, he should look up the patent specifications. I suspect he will find that every substance which can be considered wax, or can be used as wax, is protected by patent (probably out of date now). In one of the volumes for 1879 there is an account of the sixpenny phonograph, in which it is said that stearine wax was used for the "records." Essar.

[97355.]—**Mercury Interrupter.**—I have to thank Messrs. Bottone, Avery, and Drysdale for kindly answering my query. Owing to its over-conciseness, and perhaps partly also to the fact that the Wehnelt interrupter bulks so largely in men's minds just now, I have failed in making my meaning clear. What I wished to know was how the electrical contact is made in the ordinary mercury interrupter, between the mercury in the cup and the primary of the induction coil. Perhaps I was mistaken in assuming that this is done by means of platinum passing through the bottom of the cup, and it may be that copper is used. If so, and if the hole is sealed up with glass after the copper wire is passed through it, is there not a risk of the glass cracking when it cools, owing to the unequal expansion of glass and copper, and, if this be the case, how is the risk obviated? A. T.

[97381.]—**Piston-Speed for Launches.**—This was answered by "Regent's Park" in your issue of the 19th ult.; but he failed to impart the knowledge I sought, perhaps because I did not make myself understood. What I want to know is, what number of revolutions I may expect to get from a compound engine 6in. by 12in. by 8in. stroke, using steam at 100lb. working pressure, the engine running uncoupled, not driving anything, steam cut off in the h.p. at ½ stroke and l.p. at ½ stroke. I trust some one will be able to give me a little information. C. E. L.

[97382.]—**Rats.**—If the querist cannot get rid of the rats by the methods previously mentioned, I would suggest the employment of a professional ratcatcher. Rats are useful (when dead), for the pelts are always of value to make felt, or the skins for "kid" gloves. I saw it mentioned recently that in the Strand, where the old houses are about to be pulled down, there are thousands of rats, and it is certain that they abound in all the basements of London where there is any food to be obtained. To drive them away there is nothing better than catching a few and tarring them. The whole colony will leave. F. D.

[97429.]—**Tin Scale.**—Tin is easily soluble in strong hydrochloric acid, and is converted into white, nearly insoluble, powder by nitric acid. Messrs. E. and C. Kuhn, chemists, of Sechshaus, near Vienna, patented an invention for producing pure tin, good weldable iron, ammoniac, Prussian blue, &c., from clippings of white iron. Mr. Higgin, of Manchester, utilises tin therefrom for making stannate of sodium. The Panton patent (New York) tin-scrap is placed in a revolving inclined box, provided with hollow journals, through which is passed dry chlorine gas, to form and carry over to condenser bichloride of tin, which is precipitated as oxide and reduced. Mr. F. G. Martin, Bermondsey, S.E., has also worked on this subject. Also, Manhattan Metal Co., of New York, and Adolphe Ott, of the States, also; process used in Germany and Belgium. P. S. Simmonds on "Waste Products," 1873. Regent's Park.

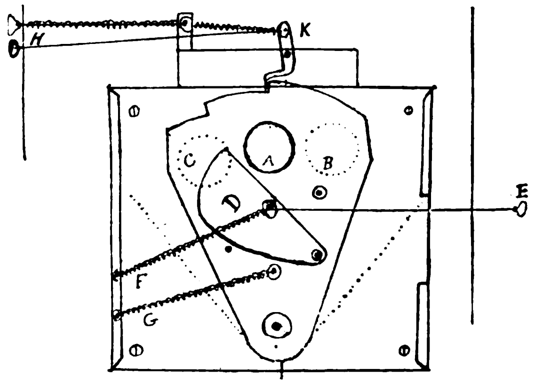
[97436.]—**Stamping Notepaper.**—The reply on p. 560 by Mr. Theodore Brown may suit the querist, but it appears very crude. Wonder whether Mr. Brown has ever seen how they impress stamps at Somerset House for cheques, &c. The ink is simply rather stiff printer's ink, and it is forced into the die either by a roller or by a dabber (not a stencil brush). The surface of the die is then wiped with a cloth, which may or may not have a little whiting on it, and the impression is taken in the usual way. A little hand apparatus can be bought at any stationer's, but most people now use a rubber stamp for common work. Dies of the kind are not in a hurry to go rusty, but when put away they are not covered with "white beeswax," but with a mixture of pure fat and plumbago—sometimes the latter only. S. H.

[97442.]—**Eyepiece.**—In this instance "Polaris" has already received replies to all his queries in "F.R.A.S.'s" usual courteous and accurate form, so that the peculiarity of certain other replies alone induces me to beg leave to draw further attention to this much and often queried subject. First, as to the three possible meanings of (1) "the theoretical limit of power," which may be either (*a*) magnification per linear inch of aperture, (*b*) minimum separation of double-stars observable, or (*c*) minimum magnitude of stars observable. Answers to (*a*) and also to (*b*) for one set of conditions have already been given with much clearness at page 535 by "F.R.A.S." while (*c*) has been taken up by Mr. Banks at page 544. Personally, I think (*a*) alone was meant by the querist, to judge from his own words, and if I also may give my experience, I should say that 30 or 40 per linear inch of aperture is about the maximum magnification possible with critical precision, for objects which present surfaces upon which details are expected to be seen—if atmospheric conditions permit.

But on the other hand, I should not limit the magnification even to 100 per linear inch of aperture, where, at times, certain stellar objects are to be scrutinised. Secondly, respecting the formula for the equivalent focus of "compound eyepieces," I find still more need for adding a little. Mr. Banks gives at p. 544, first of all, the well-known general formula which serves for all forms of compound eyepieces which have two lenses only, although, curiously enough (and peculiarly so in being presumably from the pen of a practical optician), he limits its applicability to eyepieces of the Ramsden or "positive" type, failing to notice that what he thinks necessary to add as a second "rule," suited specially to negative or Huyghenian eyepieces, is simply a roundabout way of expressing in words the shortened form of the first given formula. Line 9 of middle column at p. 537 shows how the formula he first quotes becomes simplified into what he gives as a second one adapted specially to negative eyepieces as he thinks, while, as I there have shown, the first given formula is equally applicable.

$$\frac{F_1 \times F_2}{(F_1 + F_2) - d} = \frac{2\,F_1 \times F_2}{F_1 + F_2} = eq.f.$$

are just two ways of writing the same thing in the usual familiar short language of symbols; but as already explained at p. 537, we are only justified in utilising this formula in its second form when (*d*) or the lens distance apart equals half the sum of the foci. The second form given above is Mr. Banks's expressed shortly. But should perfect accuracy in (*d*) be aimed at, we can no longer use the "half sum" originally proposed by Huyghens in order to equalise the refractions, but must use as supplementary the formula given at p. 537, first col., in which case we are forced to take the formula in its complete form as first given. Huyghens knew nothing about the wonderful coincidence connecting (*d*) with the conditions for achromatism, and which require, except for the very longest telescopes (*d*), to be made greater than the "half sum" (see 43250 quoted above). In microscopes particularly has this to be attended to, as the measurement of micro. eyepieces by the best makers will show. For my demonstration of the simple matter of diaphragm aperture in the letter just quoted, (*d*) equalling the "half-sum" was good enough for the purpose; still I there founded my deductions for the Huyghenian eyepiece on what Mr. Banks thinks only applies to the positive eyepiece. Thirdly, as to decrease of field of view by increase of magnification, I do not think the reply of "F.R.A.S." could be in any way improved upon. It was, "As the power increases, angular subtense of the stop decreases." Now, as *the stop* evidently meant by the querist and as understood by "F.R.A.S." is the diaphragm in the eyepiece, and not a stop near the object-glass—such as "O.G." speaks of in query 97457—it is very easily seen by all, that Mr. Banks has given a reply about diametrically opposed to the correct one when he wrote the following: "The field of view—is not influenced any way by a stop"; although he allows it to be "governed by magnifying power chiefly." Why chiefly? Is it not possible, as we all know, to contract the field of view very much more by a small "stop," than would be practically possible by any increase of power with which vision would be else than a dim apology for it? Indeed, for certain solar observations this is frequently done, and the spectroscope slit itself is but another form of diminished field when the instrument is used in its "analysing" form. [In my letter 43257, p. 545, first column, line 15, for "reflector" read "refractor."] H.

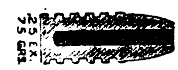


[97364.] — **Hand-Camera Shutter.** — This sketch shows the shutter open when taking a view. Before taking a view, A in fan-piece is at B, and C is at A; of course, C and B are solid metal—no holes—which covers A before exposure and after exposure; D is pulled in front of A by E when renewing shutter ready for a fresh exposure. The dotted line showing the position of fan-piece before and after exposure, F and G causing D and the fan-piece to act properly, which are very fine brass wire springs. E is very fine catgut. H is strong brass wire, with a knob that is pushed with the thumb, and is outside the camera, and when pushed causes K to release the fan-piece for either instantaneous or time exposure. The sketch is the exact size, and the holes in fan-piece and fixed front-plate are exactly opposite, and ½in. diameter, and opposite centre of lens. PHOTO.

[97456.]—**Launch.**—Yes; it is quite practical to bring the propeller tube out to one side of stern-post in a small boat where it would dangerously weaken the boat to cut the stern-post. The tendency will be to drive the boat a little out of the straight, which is easily remedied with the rudder. I fixed up the propeller in this way in a small launch I fitted. Fill up inside with pitch run in hot, and see that wood is quite dry; outside a piece of copper can be riveted on to hold things together. The job wants doing nicely, or you will have trouble. The propeller will, of course, go outside rudder, and will have a movable stay to hold it in position. When wanted out of the way, it is merely folded up. If the description of jointed shaft is not sufficiently clear to "Navigator," I will make a sketch if I can find the time. With regard to prices for the same H.P. varying so much—well, some makers are liars, and some are not, when speaking of the power of their engines. W. J. SHAW.

[97457.]—**Stopping-down Object-Glass.**—I must apologise to "O. G." for having been so long in replying to his query. My superb 4in. Cooke refractor, like his, has several stops down the tube. These are for the purpose of cutting off stray light and surface reflections, and as long as they are placed at their proper intervals according to their diameters, they in no way reduce the aperture of the object-glass. The shortest way to discover whether the stops are cutting off any useful light is to adjust the telescope to solar focus, and, turning the eye end of the instrument to the light, examine it from the object end. The full aperture of the object-glass should then appear to be illuminated from all positions in which the eye may be placed. Should this, however, not be the case, remove the stops, and, having ascertained the focal length of the o.g., find, by the following simple method, the proper distances at which the stops should be placed. Assuming your object-glass to be 4in., and its focal length 72in., drive two tacks into a plank (or one of the floorboards of a room) the former distance apart, and a third tack the latter distance away at right angles to a point midway between the two tacks; then tightly stretch a thread completely round the three tacks, and you will have a triangle representing a full-sized section of the cone of rays formed by your object-glass. Now locate the spot where the threads are apart exactly the diameter of your largest stop, and measure its distance from the two tacks. This will be the place where that particular stop should be fixed in your tube. Apply the same process to the remaining stops, and if the object-glass is a good one, it will now perform its best. I may here remark that it is not uncommon for unscrupulous makers to conceal the faults of a lens imperfect near the edge by cutting off the defective margin in this secret way, so that what pretends to be a 4in. is in reality only equal to a 3in.—or less. If, however, your instrument is by a maker of repute, and yet will not pass the test I have given, it is probable some of the stops may have become accidentally misplaced, and only need correct adjustment. NORMAN LATTEY.

[97467.]—**Rook Rifle.** — The short rim-fire cartridges will shoot very accurately up to about 35 yards, while the long and the long-rifle cartridges will kill up to about 60 and 130 yards respectively; and with a little practice you should hit a penny every time at a distance of 30 yards. The penetration of the short cartridge bullet is about 3in. of deal, and the long rifle 5in., both at a distance of six yards. I have used a Marlin and a Colt 22 cal. repeater for the last five or six years, and find that they are of very little use for rabbit shooting unless they hit in the brain. The hollow-fronted bullets are somewhat better, but many rabbits get to ground after being hit. During the late frost, I had a rabbit dug out; the spinal column was completely smashed just behind the head, yet it managed to crawl nearly a yard down the burrow. For shooting sitting rabbits and rooks I use a Marlin 25 cal. repeater, shooting a bullet like the sketch, with 10 grains of black powder and a telescopic sight. "W. S." will have to load these



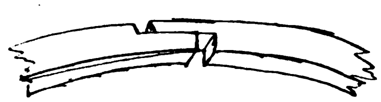
cartridges himself; but this is very simple, and the cost of a complete rig-out, including gun, telescope, and loading tackle, will be about five guineas, and if "W. S." does not bag two out of every three rabbits up to 45 yards, it will not be the fault of the gun. CLYTIE.

[97469.]—**Tender Feet.**—Take regularly a short footbath, putting a handful of bran into the water, and apply a little slice of raw beef upon the tender part. Hold your legs in a horizontal position whenever you can. T. N.

[97471.] — **Piano-Organ.** — The querist must satisfy himself by adopting the motor which suits him. Apparently the usual spring-work, as used in musical-boxes, is most suitable. A little electric motor could be employed, but that would involve a battery, unless the current could be obtained from the "leads" of one of the companies. It is not stated whether the organ is to be movable. If so, the battery would be necessary, and then I should think "clockwork" would be the best arrangement. R. S.

[97472.]—**Oil Engine.**—Much better buy a set of castings; they should only cost about 35s.—less than you can make the patterns for, and they will be correctly designed. Do not make an engine with a smaller cylinder than about 4in. by 2½in., which should give about ½B.H.P. at 400 revolutions. CLYTIE.

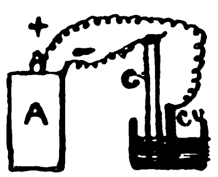
[97474.]—**Knocking in Gas - Engine.**—I would strongly advise "Country Parson" to test the tightness of the key securing his flywheel, as he may there find the cause of the knocking in his engine at every explosion. It is no use to merely try with a light hammer, which may fail to locate the trouble, as I have found on two occasions that on one of my gas-engines I have had to drive in the key with a sledge to stop a similar trouble. I may say the engine is of 14H.P., so required a good heavy hammer, a 4lb. one failing to put it right. It is not at all likely the leakage past rings is the cause of trouble. As to rings in gas-engines, it is surprising how indifferently these most important adjuncts are generally fitted, as either they have a gap in which, when in position, is a fixed stop, or they are cut across with a mere diagonal cut. Neither of these can be really made gas-tight. Quite recently I fitted a new set (four) of rings to my electric-light gas-engine, diameter of cylinder 7in., and made the joint as per sketch. I milled



out the joint—a vastly superior plan to filing—and got a perfectly gas-tight joint. Having cut the joints, as shown, I sprung the rings into size of cylinder, and took a light cut over to get a true circle, and a very few hours of working showed that the result was well worth all the trouble as against the old butt joints with a fixed stop.

Plymouth. E. H. MICKLEWOOD.

[97476.]—**Tinning Carbon.**—The first thing to do is to clean the end of the carbon you wish to tin; then place the end into a saturated solution of sulphate of copper. The arrangement is shown in the accompanying sketch. C the carbon plate



connected to the negative pole of a cell A. Cu copper plate placed with its face parallel to the face of the carbon, is connected to the + pole of the cell (you must be careful not to have the plates touching each other). When there is a fairly thick coating of copper on the surface of the carbon you wish to tin, take it quickly from the solution and rinse it in hot water, having ready a clean, hot, well-tinned soldering-iron. When rinsed run the iron quickly over the coppered surface. I say

quickly, because if the copper surface is exposed to the air it quickly oxidises; if this happens you will not get a nicely tinned surface on your carbon.

A. STAMMWITZ.

[97477.]—**Brasswork.**—The brass can be cleaned with rouge, with oxalic acid, or with ordinary "dipping acid," but it will soon tarnish unless protected by a coat of lacquer. I guess "Seeker" wants something that no one has yet found. If brass or copper is to be protected against the action of the air, it must be coated with something—a lacquer or collodion. The best way is to lacquer the work after it is thoroughly cleaned. Brass or copper will begin to tarnish directly it is exposed to the air, so the only remedy is a cover—otherwise lacquer.

R. S.

[97480.]—**Chlorine and Fluorine.**—Fluorine was first definitely isolated by Moissan in 1886 by the electrolysis of hydrogen fluoride, containing the acid potassium fluoride in solution. It had previously been found by Gore that perfectly pure anhydrous hydrogen fluoride would not conduct.

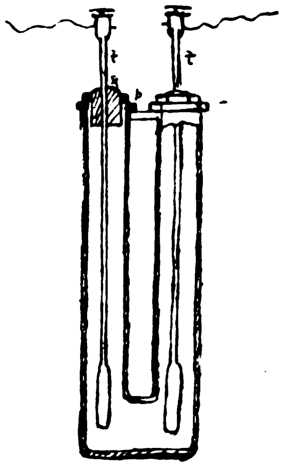


Fig. 1 shows apparatus used. The anhydrous hydrogen fluoride is poured into the U-shaped platinum-iridium vessel, with one-fifth of its weight of hydrogen potassium fluoride. The open ends are closed by fluorspar stoppers (*f*); these are ground so as to nearly fit the tube, and are then wrapped round by thin platinum foil. The electrodes (*t*, *t*,) are of platinum-iridium, held in position by leaden washers (*p*), the whole being covered with melted shellac. The U-tube is placed in a double-walled glass vessel containing liquid methyl chloride, which cools the tube to $-23°C$. On passing current from 25 Bunsen cells arranged in series, hydrogen is given off at the negative electrode, and fluorine at the positive pole. The fluorine is passed through a platinum spiral tube surrounded by methyl chloride, in order to condense any vapour of hydrogen fluoride; the last traces being absorbed by fragments of sodium fluoride contained in a platinum tube. In this manner from three to four litres of fluorine may be prepared in an hour. The reaction goes on as follows:—

(1) $2KF,HF = 2K + H_2 + 2F_2$

(2) $2K + 2HF = 2KF + H_2$.

Fluorine is a light greenish-coloured gas, with a pungent, irritating smell resembling that of hypochlorous acid. It is characterised by an extraordinary chemical activity. Sulphur is at once melted in it and inflamed; phosphorus takes fire; arsenic, antimony, and boron become incandescent; iodine inflames, and crystalline silicon burns with great brilliancy; fluorine combines with hydrogen with explosion even in the dark; organic compounds are violently attacked; cork is carbonised and inflamed; alcohol, ether, benzine, and turpentine take fire; glass is at once corroded. With liquid O as refrigerant, and in making a vacuum, it was found by Dewar and Moissan that the liquefaction of F takes place by evaporation of liquid O at a pressure of 325mm. of mercury. Boiling-point of F is $-187°C$. Density of liquid fluorine is 1·14; it still inflames turpentine at this temperature. It is a clear, yellow, highly-mobile liquid. Chlorine is interesting as being the first gas which was liquefied, viz., by Northmore in 1805—1806, who obtained it by heating chlorine hydrate in a sealed tube. Used in colour-making works and for treatment of gold ores. It was easily solidified by Faraday, about 1845, using a mixture of CO_2, snow, and ether as a cooling agent. Solid chlorine is a greenish-yellow mass melting at $-75°C$.

R. W. M.

[97480.]—**Chlorine and Fluorine.**—(1) Fluorine, the first of the halogen series, was the most recent to be discovered, it having baffled all attempts to isolate it until the year 1886, when Moissan succeeded in solving the problem. Its isolation depends upon the discovery that a solution of the acid potassium fluoride, HF,KF, in anhydrous hydrofluoric acid is an electrolyte, and that by the passage of an electric current through this solution fluorine is disengaged at the anode, or positive electrode, and hydrogen is evolved at the cathode. The primary decomposition taking place is the breaking up of the acid potassium fluoride:—

$$HF,KF = F_2 + H + K.$$

The atom of potassium, in contact with the free hydrofluoric acid present, is then converted into potassium fluoride with the elimination of an equivalent of hydrogen—

$$K + HF = KF + H.$$

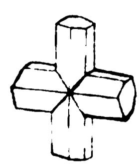
And the normal potassium fluoride then unites with a molecule of the acid to regenerate the acid salt—

$$KF + HF = HF,KF.$$

The reaction is performed in a U-tube made of an alloy of platinum and iridium, a material which is less acted upon by the liberated fluorine than platinum alone. The anhydrous hydrofluoric acid is introduced into the apparatus, and about 25 per cent. of its weight of the acid potassium fluoride is added, which really dissolves in the liquid. The tube is immersed in a bath of methyl chloride, which boils at $-23°$ C. On passing a current from 20 to 25 Grove's cells through the apparatus, fluorine is evolved at the positive electrode, and hydrogen at the negative. A more recent method (Brauner, June, 1894) is by heating potassium fluor-plumbate, $3KF,HFPbF_4$. At 200° C. this salt gives off hydrofluoric acid, and when heated to $230°-250°$ C. fluorine is evolved. With regard to its properties, it is the most chemically active of all the known elements. Fluorine appears to be colourless, judged by the small volume of it that can be viewed at once. Smell, like a mixture of chlorine and chlorine monoxide evolved from potassium chlorate and hydrochloric acid. When cooled to a temperature about $-185°$ C., it condenses to the liquid state (Moissan, May, 1897). Even gold and platinum are attacked by fluorine. (2) When chlorine is cooled to a temperature of $-102°$ C., it freezes to a yellow crystalline mass.

Bonnyrigg. GEO. W. STRATON.

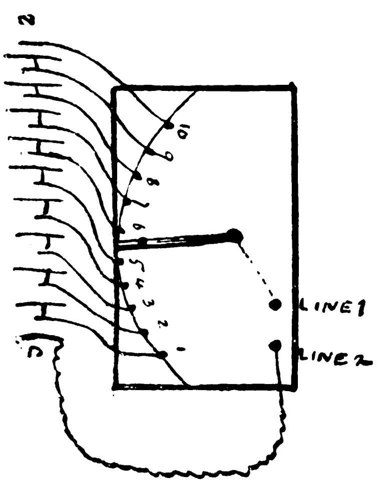
[97496.]—**Silicates of Alumina.**—Alumina has chemical formula Al_2O_3; silica or flint SiO_2. A large number of aluminium silicates occur native and constitute important minerals. Kaolin or porcelain clay $Al_2O_3,2SiO_2,2H_2O$ is produced by the decomposition of orthoclase $K_2O.Al_2O_3.6SiO_2$. Staurolite, which occurs in remarkable cruciform crystals (see figure) has the compositiom $4Al_2O_3$,



$3SiO_2$, a portion of the alumina being frequently replaced by ferric oxide; andalusite and kyanite have the formula $Al_2O_3SiO_2$; Allophane has the composition $Al_2O_3,SiO_2 6H_2O$. Specimens can be obtained from any chemical dealer.

R. W. M.

[97504.]—**Electrical.**—I trust that the accompanying sketch will answer your purpose.



S. ELLIMAN.

[97511.]—**Radiometers.**—The term "ultra-gaseous state" is used when a gas is so highly rarefied that the mean free path of its molecules becomes of appreciable magnitude—can be easily obtained by a Sprengel pump. A fair state of ultra-gaseity would give M.F.P. of 5cm. (2in.), the pressure would then be about $\frac{2}{1000000}$ atmos., and the number of molecules per c.c. about 2×10^{13}. The properties of the ultra-gaseous state, as far as they are purely thermal or mechanical, are best studied by means of Sir W. Crookes's radiometer (see Fig. 1).

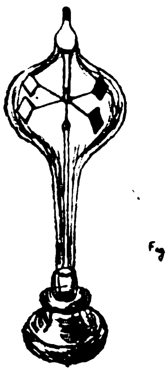


Fig 1

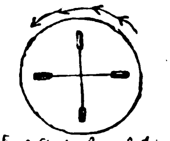

Fig. 2 Direction of revolution of radiometer.

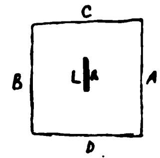

Fig. 3.

It consists of a glass vessel, at the bottom of which is a glass support carrying a fine steel pivot. On this revolves a light glass cup carrying four aluminium vanes, fixed vertically to the extremities of a pair of light horizontal arms at right angles. One side of each vane is coated with lampblack and the other left bright, and arranged so that all the black faces look the same way round a horizontal circle. The interior of the vessel contains air in the ultra-gaseous state. (See Fig. 2 for direction of rotation.) If the gas in the vessel falls short of the ultra-gaseous state, the vanes rotate very slowly in a direction opposite to the arrow. As the ultra-gaseous state is approached they become stationary, and when it is well maintained they behave as shown in figure. If exhaustion is carried too far they again become stationary. All these actions have been mathematically investigated by Clerk-Maxwell; we shall confine our explanation to general terms. (See Fig. 3.) Let A B C D be a vessel containing gas wherein is suspended a disc whose right face, R, is black, and its face L bright, and let the vessel be exposed to radiation equally all round. Then, since R is a better absorber than L, it becomes hotter. Now, temperature of gas close to either face is practically equal to temperature of face, and since the higher their temperature the greater the molecular velocity μ of mean square, the velocity is greater over R than over L. From the fundamental equation $p = \frac{1}{3} \rho \mu^2$ it is therefore clear that if the difference of temperature between R and L does not establish any appreciable difference of density, the augmentation of μ must render the pressure on R greater than on L, and so drive the disc (if free to move) from right to left. But if the difference of temperature sufficiently diminishes the density over R as compared with that over L, this diminution may, in accordance with equation (ρ = density of gas), just compensate for augmentation of μ, the pressures on the two faces remaining equal, and no movement occurring; or it may be over-compensated, in which case the disc moves from left to right. Consider three cases:—Case 1. When gas falls considerably short of ultra-gaseous state. Here the hotter molecules, after rebounding from R, encounter numerous others which obstruct their progress towards A; this diminishes the density over R, and increases it over L, and so over-compensation above referred to is produced; the disc therefore moves to the right. This corresponds to rotation of the radiometer opposite to arrows (Fig. 2) when insufficiently exhausted. Case 2. When the ultra-gaseous state is nearly attained. Here the rebounding particles still encounter others, but not so many; the obstruction and consequent flow from R to L is less, and the diminution of pressure just compensates for the augmented velocity; the disc accordingly does not move. This corresponds to the non-rotation of the radiometer vanes when the exhaustion has reached a certain pitch. Case 3. When the ultra-gaseous state is well maintained. Here the rebounding particles encounter practically no others; the flow and density diminution are practically nil, and there is nothing to compensate for the augmented velocity; the disc therefore moves to the left. This corresponds to the ordinary action of a properly made radiometer. The reason the radiometer does not revolve when the exhaustion is

carried too far is because the actual pressures on each side of the vanes are so minute that their difference is insufficient to overcome the friction between the cup and the pivot. It should be noted that we have supposed vessel A B C D to be exposed to radiation equally all round. This is quite unnecessary with the radiometer, since if, in a certain position, the bright face of one vane is towards the source of radiation, and dark face away from it, the effect of the bright face getting hotter is more than compensated by the vane at the other extremity of the same arm. Case 3 is probably reached when mean free path = R A (Fig. 3), borne out by fact that the larger the bulb the more complete must be the exhaustion. If a gas between two surfaces be such that mean free path of molecules is not much less than distance between the surfaces, it is called a Crookes's layer. Therefore a radiometer only works when there is a Crookes's layer between the vanes and the bulb. R. W. M.

[97517.] — **Propellers.**—Herewith I give particulars of two large fast twin-screw ships at a moderate and top speed. One is a recently-built cruiser, the other a mail steamer.

	H.M S. *Diadem.*		S.S. *Normannia.*	
Length	435ft. 0in.		498ft. 9in.	
Breadth	69ft. 0in.		57ft. 5in.	
Draught	26ft. 0in.		22ft. 3in.	
Block coefficient	0·495		0 582	
Displ. (tons)	11,000		10,590	
Diam. of screws	16ft. 9in.		18ft. 1½in.	
Pitch of screws	22ft. 11in.		26ft. 9in.	
Developed surface	116sq.ft.		175sq ft.	
Speed of vessel (knots per hour)	20·72	16·01	20 75	14·53
I.H.P.	17,104	6,277	16.244	4,310
Revs. per minute	118·6	86 9	92·5	60
Slip of screws	23°/。	17 9°/。	15°/。	8·2°/。

The above examples are the nearest I could get to the speeds required; the developed surface given is for both screws. I suppose your correspondent need not be warned that the slip per cent. as usually stated (and given above) is only the "apparent" slip. To find the true slip we require to know the speed of "wake" or shell of water which accompanies every ship in motion. This wake is a function of block coefficient, length, and speed. Hitherto practical men have only been able to get approximate values of this important quantity.

Glasgow. CLUTHA.

[97522.] — **Solution Wanted.** — The indeterminate equation of "E. H. R."—viz.,

$$16v + 13w + 9x + 21y + 5z = 17(v + w + x + y + z)$$

becomes by transposition—

$$4y = v + 4w + 8x + 12z$$
$$\therefore\ y = \tfrac{1}{4}v + w + 2x + 3z.$$

Therefore if v be any multiple of 4, we may give to w, x, z any integral values we please.

West Norwood. HENRY T. BURGESS.

[97523.]—**Curious Geometrical Figure.**—If "E. H. R." will get a piece of the gummed margin of postage stamps and fold it with a half-twist, as he has done, and then cut it through longitudinally, he will find something more curious than the fact of its having only one edge and one side. He will get one ring double the diameter and half the width of the original ring. If this is cut through again the result will be two rings linked together like a chain, and, of course, one quarter of original width. Take another piece and fold it with a complete twist—this is, two half-twists—then cut through lengthwise, and the result will be *two* rings of same diameter as the original. If a ring is folded with three half-twists, the result, after cutting lengthwise, will be one ring double the diameter, but with one side twisted round the other like a knot. By repeated cuttings of these rings the convolutions become so complicated as almost to defy tracing them. The more twists given on first folding, the more complicated and curious the result. I saw this given many years ago as a kind of illustration suggestive of a "fourth dimension of space." A ring with one half-twist has only one edge and one side, because the twist has brought the outside edge into line and continuous with the inside edge, and the top side has been turned over and brought surface to surface with the under side. All odd twists, no matter how many, produce, when cut lengthwise, a ring double the diameter with the number of twists also doubled. All even twists produce two rings of same diameter, each one of which, if cut through again, produces two rings, and so on indefinitely; the odd twists, after the first cutting, doing the same. Try one with four half-twists, and one with five; the result is not only in the highest degree unexpected—it is simply bewildering. JAMES PARIS.

[97525.]—**Threshing.**—The first process, the threshing, is performed by a rapidly-revolving drum, having about six or eight beaters bolted to its circumference. This is surrounded for about a third of its circumference by a concave or breast-work capable of adjustment nearer or farther from the drum; the sheaves, after the bonds have been cut, are opened out and dropped on the drum in as even a stream as possible, being carried between the drum and concave, some of the grain being knocked out by the beaters, and some rubbed out between the beaters and concave. After the straw, &c., escapes from between drum and concave at the bottom, it falls on the shakers; these, generally four or five in number, are wooden frames with cross-bars, something like ladders with the staves very close together, and are mounted on cranks in such a manner as to carry the straw forward, at the same time giving it a severe tossing, and so shaking out any loose corn which may not have separated from it. When first leaving the drum the straw is delivered over the end of shakers, whence it falls to the ground ready to be taken away. Under the shakers is a reciprocating kind of wooden tray (the riddle) which catches the grain and short straws, &c., which work along till they come to a place where the tray is perforated with holes about ¾in. or 1in. in diameter; the grain and chaff fall through these, and the short straws pass on over the end, where they fall to the ground and are called cavings. The grain and chaff, after falling through the riddle, are met by a blast from a fan, which blows out the chaff, the grain going on to sieves which remove anything larger than the grain, such as small pieces of stick or stones, &c. It then goes on to an elevator, and if the machine is a double-blast finishing machine, and wheat is being threshed, it may be turned through a kind of secondary drum to knock off any chaff which may adhere to some of the grains. It then goes before another blast, and through a second set of sieves, and finally into a revolving screen, which takes out cracked or shrivelled corn, the best passing right through the screen into the sack. The screens usually make three divisions of the grain, and are adjustable. When barley is being threshed it is caused to pass through a cylinder, through which runs a spindle studded with knives, which cut off the awns or beard of the barley; the knives act as a screw conveyor. In the makers' catalogue they generally give diagrams showing the different parts of machine. LOYAL ENGLISHMAN.

[97528.]—**Power for Motor.**—Theoretically, the power required to drive a dynamo having an output of 40a. at 100v., is 5·36H.P. Practically, it will not be less than 6H.P. In like manner, the theoretical output in H.P. of a motor excited by a current of 40a. at 100v. would be 5·36; but, allowing for conversion losses, it will probably not exceed 4H.P., or less, if the distance to which the current has to be conveyed is considerable. S. BOTTONE.

[97528.]—**Power for Motor.**—If these motors are of moderately good design, an efficiency of 85 per cent. may be assumed. Consequently, with an electrical H.P. of 4,000 watts (100v. × 40a.) as a dynamo either of the machines will require $\frac{4000}{746} \times \frac{100}{85} = 6{\cdot}28$B.H.P. In the same way the motor when supplied with 100v. 40a. will give out $\frac{4000}{746} \times \frac{85}{100} = 4{\cdot}55$B.H.P.

A. H. AVERY, A.Inst.C.E.
Fulmen Works, Tunbridge Wells.

[97528.]—**Power for Motor.**—You would require 5B.H.P. to drive the dynamo, and you might reasonably expect to get 4B.H.P. to 4½B.H.P. on the shaft of the motors, if both machines are of modern design and efficient.

Dudley. WEBSTER, MICHELSON, AND CO.

[97531.]—**To Mr. Avery.**—If the Lahmeyer dynamo is to be built exactly same size as the reduced copy in the December *Model Engineer*, it will be necessary to substitute a cogged drum armature, or the magnetic reluctance of the circuit will be too great. I should advise the following:—Cogged drum armature, six teeth, wound with 360 conductors No. 24 S.W.G.; field coils, 440 turns of No. 22 S.W.G., connected in shunt; output 10 volts 3 amps. at 2,800 revs. as a dynamo, or $\frac{1}{15}$B.H.P. as a motor at the same speed.

A. H. AVERY, A.Inst.E.E.
Fulmen Works, Tunbridge Wells.

[97532.]—**Electro-Motor.**—To MR. BOTTONE.—Altogether too small and too skimpy to make a good dynamo. Put in a tripolar laminated armature; wind this with about 2oz. No. 24 silk-covered wire. If now you can manage to get 8oz. No. 26 on each limb of the F.M.'s, and connect these up in shunt, you will get the best attainable results—viz., about 6v. 1a. at 3,000 revs. Current required to drive as a motor, 1a. at 6v. pressure. S. BOTTONE.

[97534.]—**Turning Vulcanite.** — Vulcanite is worked and turned like the hard woods, scraped and filed smooth, and receives a delicately fine, even surface, rather than a polish, first with emery-paper or the powder on rubbers with oil, and is finished with rottenstone powder and oil applied in same manner, and then the dry powder, which many apply in palm of hand. REGENT'S PARK.

[97534.]—**Turning Vulcanite.**—Ebonite is very easily turned by hand in an ordinary lathe, using a sharp chisel as for wood. Try French polish.

Salisbury. E. R. DALE.

[97534.]—**Turning Vulcanite.**—The best way to turn this material is undoubtedly with the slide-rest, using sharp-pointed dead hard tools. Flat and round edges are smoothed after first two or three cuts, and can only be used for round and hollow parts with a grindstone handy. Ebonite takes a beautiful polish by fetching out scratches with emery cloth, then finally using 00 blue-back, afterwards oil and chamois leather. Vulcanite may be treated same way. ELECTRO.

[97536.]—**Lacquering Bedstead.**—"W. A. H." may proceed in following manner:—Procure from chemist or colour merchant a sufficient quantity of lacquer of (I should recommend) a light shade, it being easier to manipulate; also some methylated spirits. With the spirits wash off the old lacquer, then heat the rail with Bunsen burner till you can just bear your hand on it; then apply the lacquer with a broad camel-hair brush in very light thin coats, waiting till one coat is dry before putting on another, which only takes a second or so, keeping up the necessary heat by the Bunsen. Rail may be polished before lacquering, but must be free from grease. ELECTRO.

[97537.]—**Induction Coil.**—To MR. BOTTONE.—You will find that discs of paraffined paper, built up to $\frac{1}{16}$in., will be quite equal in efficiency to vulcanised fibre, or rather superior, if anything. But the paraffin must be good, and should have been previously melted over some dried powdered chalk, to neutralise any acidity. Of course, the clear melted paraffin must be decanted off the chalk sediment before use. The paper circlets must be ironed together, so as to form a compact mass of the desired thickness, and should fit the tube tightly. S. BOTTONE.

[97538.]—**Wood Connecting-Rods.**—Wooden connecting-rods have greatly taken the place of iron ones on threshing machines, as they bend and require no oil or grease. E. R. DALE.

[97539.] — **Wood Connecting-Rods.** — First cost, to enable machine to be sold for less than if fitted with metal. £ s. d. is the governing factor in all productions. MONTY.

[97540.]— **Quick - Drying Black Paint.** — "Constant Reader" does not say if he wants his paint dead or glossy; but, if either, I think he will have a job to make it cover on white ground. In fact, he will find it, I'm afraid, impossible. The quickest drying will be the dead or dull, which you can varnish afterwards if required glossy. The following may suit you:—Get a tin of drop black ground in turps, and mix with turpentine till thin enough, and add sufficient gold size to bind it or to keep it from rubbing off. Very little is sufficient. I may say it will not weather without being varnished, but would last all right inside providing there is no handling. HOUSE PAINTER.

[97540.]—**Quick-Drying Black Paint.**—Black enamel will be suitable, or he can rub up drop of ivory black in a little French polish, and thin to suit with methylated spirits. FRED DAVIS.

[97540.]—**Quick-Drying Paint.** — Lampblack ¼lb. Make this red-hot, leave to cool, then crush to powder; then add spirits turpentine half-pint. May be worth a trial on small scale; lay on quickly. REGENT'S PARK.

[97541.]—**Planing Machine.**—I think 3in. is thick enough for the size you name. In reference to the rack and wheels, double-skew teeth are better than plain spur-gears if the teeth are made correctly as parts of true spiral. But there the difficulty comes in. The helical teeth would be cast, while spur-teeth can be cut, and have no backlash. Probably you know that the Sellers planers are rack-driven by a worm, and run remarkably smooth. An alternative would be a screw with differential bevel-wheels to operate it; or a crank drive, which is more precise, like a shaper. J. H.

[97541.]—**Planing Machine.**—To "J. H."—ERRATA.—I notice thickness of table is given as 3½in., it should be 2½in., and for the word "beams" read *bearers*.

Bromley, Kent. A. F. SHAKESPEAR.

[97544.]—**Welding Compound.** — Borax 10, salammoniac 1; grind together; fuse until spume has gone. When clear, pour out to cool and concrete. Grind to powder, raise steel to bright yellow heat, dip into powder, heat as before, and hammer. Or, pulverised white marble; heat pieces, roll in marble, and hammer. (A. A. Hopkins.) REGENT'S PARK.

[97544.]—**Welding Compound.**—The following seems much used:—1 part salammoniac, 10 parts borax. These are pounded together and fused until clear. It is then poured out, and allowed to cool, when it is then pounded to *powder*. To temper a chisel: first heat the chisel in the fire to a dull red heat, cool the point of it in

water, and rub with sandstone. When the colour of brown yellow comes to the point plunge it into water. The temperature is 500° Fahr. STUDENT.

[97543.]—**Indicated Horse-Power and Probable Brake Horse-Power of Compound Engines.**—Assuming Boyle's law, we get that the final pressure is 30lb.; then, for low-pressure cylinder—

$$p_m = \frac{60}{2}(1 + \log_\epsilon 2) - pb\ (= 3\text{lb.})$$
$$= (30 \times 1{\cdot}69) - 3 = 49{\cdot}2\text{lb.}$$

Then, for high-pressure cylinder—

$$p_m = \frac{120}{2}(1 \times \log_\epsilon 2) - 49{\cdot}2$$
$$= (60 \times 1{\cdot}69) - 49{\cdot}2 = 52{\cdot}7\text{lb.}$$

$$\text{I.H.P.} = \frac{2\ P\ L\ A\ N}{33{,}000}$$

For H.P.C.—

$$\text{I.H.P.} = \frac{2 \times 52{\cdot}7 \times 114 \times 180}{33{,}000} = 96\text{H.P.}$$

For L.P.C.—

$$\text{I.H.P.} = \frac{2 \times 49{\cdot}2 \times 285 \times 180}{33{,}000} = 152\text{H.P.}$$

Total I.H.P. = (96 + 152) = 248I.H.P. Brake horse-power = 75 per cent.

$$\frac{75}{100} \times 248 = 186\text{B.H.P.}$$

These values are too high, as sufficient data are not given for accurate calculation. STUDENT.

[97546.]—**Transformer.**—To MR. BOTTONE OR MR. AVERY.—Premising that in order to make such a transformer of small size you must use in conjunction with it a suitable resistance or self-induction coil to pull down the current to 8 amps., you will find that the following proportions will give you good results:—Iron core, 7in. long 1¼in. diam., built up of No. 22 soft-iron wire; heads of bobbins should be soft-iron plates fitting tightly on the core. The whole should be dressed with india-rubber tape, then wound with ½lb. No. 18 d.c.c. for the primary, and ¼lb. No. 14 d.c.c. for the secondary. If the whole coil is inclosed in a roll of soft sheet-iron, screwed to the bobbin-heads, it will work all the better; but, of course, holes must be put through this covering to admit of the passage of the ends of the primary and secondary wires—which holes should be bushed with ebonite. Could not well be used with direct current. S. BOTTONE.

[97547.]—**Induction Coil for Motor.**—To MR. BOTTONE.—For your particular purpose, and especially using such small current batteries as those you name, the wire of the primary presents far too high a resistance. I make no doubt that if you remove the 24, and substitute for it an equivalent weight of No. 18 d.c.c., you will do all you desire. (2) It is possible that I used wire of somewhat finer gauge than yours. B.W.G. is not a standard size, and varies a good bit. It may also be that I made some mistake as to the precise weight. Anyhow, four layers is the amount I used; but not for a motor-car coil. S. BOTTONE.

[97549.]—**Hardening Soft Steel.**—For thin steel use:—Beef suet 3lb., train oil 1½gal., wax 6¾oz.; add rosin 1½lb. REGENT'S PARK.

[97549.]—**Hardening Soft Steel.**—Heat the articles to be hardened in a muffle to a bright red; then plunge them into common linseed-oil. They can then be polished, and let down to the required shade of colour by any of the usual methods. As I have had no experience with whale oil, I cannot say if it will harden steel. You might as well add brickbats to it as to put resin or potash in it so far as the effect on the steel would be, so that "Polished Pincer" will do well to keep to pure oil. I presume "P. P." is using a good-quality cast steel. E. W. FRASER.

[97550.]—**Electrical.**—Very little is to be gained by coupling-up a voltmeter when charging as you state. Couple your three bichromate cells in series, and take a reading with the voltmeter to see whether they are giving six volts. Now couple the cells direct to the accumulator. After a fair time of charging uncouple the accumulator, and test it alone with the voltmeter. When it is fully charged it should indicate 4·4 volts on the meter. The amount of oil of vitriol in a one-quart cell will be about 6oz., thus:—Water, 1 pint; bichromate of potash, 3oz.; oil of vitriol, 3oz. S. BOTTONE.

[97551.]—**Leather to Glass.**—Bicycle-puncture solution or Prout's or marine glue, or shoemaker's paste or glue-paste will do this if no wet comes near. FRED DAVIS.

[97551.]—**Leather to Glass.**—Secotine. E. R. D.

[97553.]—**Magnetic Induction.**—Purely a matter of convenience. When a mass of iron (an armature, is placed between the poles of a magnet, it completes, more or less perfectly, according to its proximity, the magnetic circuit, and at every alteration in the strength of the magnetic field current can be taken off from conductor surrounding the entire circuit at any point, so that if independent coils are wound round any portion of the field-magnets, current can be taken from these, as well as from the armature. So in the coil, the magnetic circuit may be completed, or nearly completed, by making the core-wires twice as long as the bobbin, and binding them over to nearly meet at the centre. Then, of course, a separate contact-breaker is required. This is, in fact, the form given to the "Hedgehog" transformer. S. BOTTONE.

[97556.]—**Glass.**—"Cristal" corresponds to our English words "flint glass," which is a heavy lead glass. "Cristal de roche," like our rock crystal, is sometimes used to indicate quartz or pebble, same as used in the best spectacles; but no large windows are made of this, for the simple reason that no very large masses of transparent quartz are found. S. BOTTONE.

[97557.]—**Leather to Glass.**—The following cement will stick pretty well anything: 1 part indiarubber, 12 of coal-tar. Heat gently, and mix; then add about 18 parts shellac. It should be used hot. E. W. FRASER.

[97558.]—**Motor Crankshaft.**—Malleable iron is not suitable for crankshafts, being too soft and liable to blow-holes. It is more suitable for any thin flat or hollow work. The so-called cast steel is more frequently mall. iron. There is Mitis iron, which might suit, made from Swedish wrot. iron to which a small quantity of aluminium has been added. Why not make two small cranks, with a coupling between? This is the usual method adopted. MONTY.

[97560.]—**Cellulose Packing.**—Bloxam gives cellulose when pure is white, opaque; is infusible and insoluble in all ordinary solvents. Dissolved by Schweitzer's reagent, and presumably has long life. REGENT'S PARK.

[97561.]—**Paint and Oil for Models.**—Has "Cymro" tried vaseline on the bright parts? I could not say if it would do, but it may. I do not think you will do better than use Brunswick or, what is better, Japan black; both quick-drying, and will stand steam heat. HOUSE PAINTER.

[97561.]—**Paint and Oil for Models.**—"Cymro" should use one or the other of the muchly advertised sewing-machine or cycle oils for his models. Blacklead and tallow mixed is grand for cylinder grease. When putting models away, coat them with common vaseline. It never dries, and does not affect steel or iron. I once had a £20 model nearly ruined through putting it away coated with machine oil; so do not use it, except for bearings. Paint to stand hot water can be got of any colour at any colourman's. Personally, I prefer Maurice's bath enamel. By the way, "Cymro" should not paint his cylinders; they should be lagged. E. W. FRASER.

[97562.]—**Water Bath.**—Because water will never boil unless it can circulate freely, and the metal holding it prevents this. FRED DAVIS.

[97563.]—**Wireless Telegraphy.**—There are two ways open to you. (1) Arrange the relay with the armature horizontal, and nearly balance it by a short wire and counterpoise; or (2) control the armature by means of a very fine helix of very fine wire and controlling screw. S. BOTTONE.

[97564.]—**Cleaning Enamelled Slate.**—I wash mine carefully with soap and warm water, and, if not smooth, French-polish it with a little black stain dissolved in it—like black polishing is usually done. FRED DAVIS.

[97569.]—**Automatic Duplex Diaphragm.**—This consists of two ordinary cells joined together with a tube, to allow of a second outlet at right angles, like the letter T; the usual floating weight and limiting screw are fixed to one cell, and the glass diaphragm is placed in the other, and the two connected with a long needle. I am greatly disappointed with mine, as it gives far less sound than the ordinary (single) one. FRED DAVIS.

[97570.]—**Specification for 3in. Spark Coil.**—To MR. BOTTONE.—Your general plan is good. The only point of weakness is the ebonite tube: it should not be *less* than ¼in. in the shell. However, you can probably use your existing tube with perfect safety if you bind it round with well-paraffined demy paper until you have increased the outside diameter to 1½in. Put 12oz. of wire in each division. Ebonite is polished by rubbing with soft flannel, dusted with putty powder, and moistened with paraffin oil. S. BOTTONE.

[97573.]—**Bare Patches on Animals.**—Generally caused by a skin disease, a kind of eczema, due to too much fat food. Let doggie have more biscuits, more grass, and less meat. Pussy will benefit by being kept to bread and milk. To effect a rapid cure give 5 minims a day to each animal of Fowler's arsenical solution to the cat in the milk, to the dog on bones. This solution is flavoured with *lavender*, and some dogs object so strongly to this smell that they will not touch food containing it. In this case ask your chemist to give you the *acid* arsenical solution; this has no smell or taste. Of course you must not give more than five drops; otherwise you may kill your pets, instead of curing them. S. BOTTONE.

[97573.]—**Bare Patches on Animals.**—These are due to weak health. Strumous or scrofulous children and aged people lose their hair, both from same cause—weak health, causing degeneration of the hair-supplying glands. The only remedy is raising the "tone" of the animals—plenty of fresh air, cleanliness, wholesome food, tonics, &c., just like human animals. FRED DAVIS.

[97573.]—**Bare Patches on Animals**—are probably mange. Try this as a simple one of some nine in Beasley's "Book of Recipes." Ointment: Charcoal powder 2oz., sulphur 4oz., salt tartar 1dr., Venice turpentine ½oz., lard 6oz. REGENT'S PARK.

[97573.]—**Bare Patches on Animals.**—These are due to a parasite. Persons coming in contact with the animals may be affected in the same way. The cure is dilute acetic acid; use each day till the hair can be distinguished on the patches, when the cure is complete. ROY.

UNANSWERED QUERIES.

The numbers and titles of queries which remain unanswered for five weeks are inserted in this list, and if still unanswered, are repeated four weeks afterwards. We trust our readers will look over the list, and send what information they can for the benefit of their fellow contributors.

Since our last "Optical L." has replied to 97301.

QUERIES.

[97575.]—**Crowdus Battery.**—Full particulars of same will oblige.—BATTERY.

[97576.]—**Edison Phonograph Grand.**—A rough sketch and description of speaker and records of this instrument will oblige.—PHONO.

[97577.]—**Electric Organ Action.**—Can any reader tell me what size wire to use for electro-magnets for organ action? How much wire per magnet, and what size core? The armature-valve is a free ferrotype disc, ⅝in. diam. What size wire for cables? Flexibility is no object, as console is fixed. Will cotton-covered wire do for magnets and cables? I am using three or four Leclanché cells. Should they be connected in series or parallel? Robertson's excellent book gives no practical information on this branch of the organ trade. Any hints would be very acceptable.—ZADDEUS.

[97578.]—**Lathe Matters.**—Would some of our lathe experts kindly advise as to the adaptability of the "Barnes" or "Star" 4½in. lathes for the fitting of milling attachments? Possibly some of our readers may have such attachments fitted to lathes of the above or other American makes. I feel sure that a description of same would be of interest to many of our friends interested in lathe matters. Personally, I fear the "Barnes" 4½in. lathe would not be sufficiently rigid for milling purposes, except very light work. I feel sure the 4½in. "Star" lathe would be more satisfactory in this respect, and it also has the advantage of automatic cross-feed. The former weighs 270lb. and the latter 333lb., I believe. I know the workmanship in the "Barnes," also that the metal is intelligently distributed, although the tool is light. I am wishful to obtain information in this respect with regard to the "Star."—HENRI.

[97579.]—**Affection of Moustache.**—Can any of "ours" give a remedy for the above? I have consulted my club doctor, and he says he has read of the affection somewhere, and that it is "hair jointed like bamboo," but gives no remedy, merely saying that it will go off again, and that it is not due to parasites, or anything of that kind, and that it is not likely to spread to any other part of the body or head. There are as many as half a dozen joints on some of the hairs, and they look as though they had been singed. They are easily broken off at the joints, and are then liable to split. I hope some of "ours" will be able to assist me in getting rid of this affection.—J. E. W.

[97580.]—**Sea-Water and Bacteria.**—I shall be much obliged if some of your correspondents can give me any information on the following points:—(1) What effect has sea-water on anaërobic and aërobic bacteria? (2) If a system of sewers is flushed by salt water, the sewage being carried to a septic tank and bacterial contact beds, would the bacteria do their work as efficiently as they do it in fresh water? (3) If 25 per cent. only of the water is salt (sea-water), the remainder being fresh, what effect would this have on the bacteria? (4) Have any experiments been made in this direction?—S. C. B.

[97581.]—**The Sun.**—Can prominences be seen with a

spectroscope on a 5in. achromatic? How many prisms? Direct vision or radial?—CORONA.

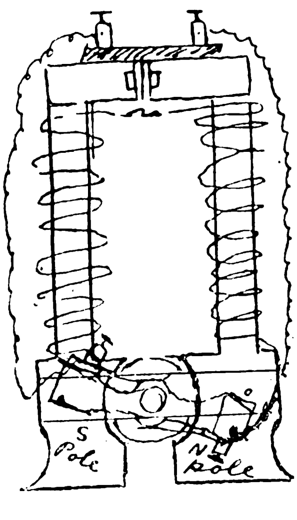
[97582.]—**Model Traction.**—Will some mechanical friend explain the method of the fast and slow speeds. and the way they are arranged on a traction engine? Also, how is the compensating gear arranged on the road wheels? A sketch would oblige.—N.

[97583.]—**Mercurial Column.**—Could any reader give instructions how to construct mercurial column for the testing of pressure gauges?—USAGE.

[97584.]—**Bone Bearings.**—Can "Jack of All Trades" say whether these would work well, with salt water only as a lubricant, in such bearings as those for the gunmetal journals of centrifugal circulating pumps for marine work? These are usually of lignum vitæ.—W.

[97585.]—**Electric Cables in Coal Mine.**—Will any kind reader let me know how electric cables are run in a coal mine? Are they put on insulator or not? Do they use solder iron or ladle for branch wire in a fiery mine (for electric motors)?—JOHN HOLDEN.

[97586.]—**Plating Dynamo.**—To MR. BOTTONE.—You replied to my query, "Plating Dynamo" (97242). Having come into possession of some 22d.c.c., I put that on the field-magnets, eleven layers on each, which just took up all the available space, and seven layers on armature 18d.c.c., but I cannot get it to work. I have magnetised the field-magnets with a No. 3 Leclanché cell. I send sketch showing connection, which perhaps I have



wrong. It does leak in winding, for I have tested it. The commutator has an oblique cut 1/16in. wide in it. If you rectify the cause of failure, I should be obliged.—SECULARIST.

[97587.]—**Motor Car.**—I should be obliged if the writer of the articles would give me a little information on the construction of core boxes for the cylinder, and especially the end for water jacket. I have a foundry of my own, and can manage any ordinary castings, but have had a difficulty with water-jacketed ones. I have made several gas-engines, and to get over the difficulty have brazed the water jacket on separately.—J. M.

[97588.]—**Acetylene Burners.**—I cannot get a burner for optical lantern work that is satisfactory. Will someone kindly assist me?—LANTERNIST.

[97589.]—**To Mr. Bottone.**—I wish to construct a small dynamo continuous current capable of giving a pressure of 40 volts, and sufficient current to light eight 10c.p. lamps. I also wish to charge accumulators with it. What kind of armature do you recommend? Also, what length and gauge of wire shall I use for armature and field-magnets, and what should be their dimensions?—J. O. T.

[97590.]—**Sound.**—At Butha Bathe, and at Ahlotsi, in Basutoland, they can hear the big guns at Ladysmith —130 miles away. They want to know—1. Does rain, not fog, help, retard, or affect sound as to its travelling distance? 2. Does very rare atmosphere help, retard, or affect sound—Ahlotsi plateau is over 6,000ft.? Would that atmosphere help or retard, as compared with the atmosphere of the sea level? 3. Would the fact that the sound has to cross a range of mountains help or retard?—S. BOXWELL.

[97591.]—**Differential Gear.**—Will any reader kindly explain the action of the common form of differential gear, as applied to traction engines, &c.? A sketch or two would be very much appreciated.—COMPENSATE.

[97592.]—**Silicate of Alumina.**—I am much obliged to Mr. Bottone and Mr. Forman for replies on this subject. I want a silicate of alumina which would fuse and become very hard when subjected to a powerful heat, giving as a product something like glass. Which, amongst the various things named, would be best?—S. W.

[97593.]—**Wireless Telegraphy.**—I should be much obliged if Mr. Bottone would kindly tell me what size, and how to make a Leyden jar to use with a ½in. spark coil for wireless telegraphy, and also whether it is best to use one or two jars?—CARLIOL.

[97594.]—**Motor-Car.**—To THE "WRITER OF THE ARTICLES."—Will you kindly say if I can use common paraffin oil instead of petrol in the motor you are describing? If not, what alterations would be required? I see motors for paraffin are advertised in this paper. Ten miles per hour will be the fastest speed I shall want to travel. Will you also tell me if there is a tax or license on motor-cars? I have been told that all motor-cars must be fitted with gear for backward motion. Is that so? I cannot find anything relating to the Locomotives on Highways Act in the "E. M."—W. H. W.

[97595.]—**Motor-Car.**—Could the "Writer of the Articles" please give me some idea of the lowest cost of making the present motor-car? I should make it of wood as described, and with solid rubber tires on the wheels. The woodwork to be stained and varnished, as I should use loose cushions on the seats. I should also like to know the length and breadth of the car, and the height of the wheels?—CARLIOL.

[97596.]—**Kitchen Range.**—Would some competent subscriber give instructions, with working drawings and scantlings of materials, for making a small wrought-iron kitchen range to burn solid fuel, with oven and hot-water vessels, adapted to a family of three or four persons?—M. G. MATTILICH.

[97597.]—**To Mr. Bottone.**—Thanks for your reply in Jan. 5 concerning reversing arrangement of armature. Will you kindly inform me if the method described in Fig. 2—viz., series wound motor—is applicable to motors of considerable power, say two-horse?—J. H. C.

[97598.]—**Elleviegen Light.**—What quantity of oxygen gas does a saturator require per hour? Could a saturator be used with an injector jet?—G. P.

[97599.]—**Permanganate of Potash Battery.**—Could Mr. Bottone, or any other electrician, inform me the best way to make the above battery, as I am told it is stronger than the bichromate?—J. W.

[97600.]—**Nickel or Silver-Plating Small Articles.**—The best method of doing same, whether by dynamo or batteries? I have plenty of power and tools, &c., but I have practically no knowledge of it. Will some kind reader oblige and name a book on the subject?—PLATER.

[97601.]—**Power of Boiler.**—Will a boiler, 30in. by 12in., with internal firebox and a single flue, and a working pressure of 50lb. per square inch, drive an engine 3in. bore, 1in. stroke, at 100 revs. per minute? If not, what sized engine will the boiler steam if the stroke and speed are to be kept the same? The engine will be of the vertical inclosed and balanced type, and run in oil. With steam cut-off at ¾in. stroke, about what power should I get? I should add that the cylinder is double-acting.—E. W. FRASER.

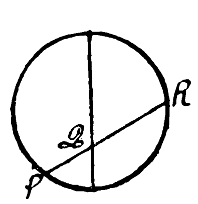
[97602.]—**Motor-Car Engine.**—Would the writer of the articles on "Motor-Cars," or any correspondent, kindly tell me what alterations would have to be made to drawings in "E. M." to increase power to 4 B.H.P.?—POWER.

[97603.]—**Dilution of Creasote.**—Will some of "ours" oblige by giving information as to the best method of diluting creasote to the extent of from 1 part of creasote to 3 or 4 of the diluent? The diluent must not exert a deleterious influence on wood, and must be cheaper than creasote.—TIMBER.

[97604.]—**Mixed Jet.**—How do the oxy-hydrogen and oxy-coal-gas lights compare as regards brilliance? Is the manipulation as regards working of jet the same in each case?—LYMNOS.

[97605.]—**Grating.**—How may Thorpe's glass-plate diffraction grating be applied to camera, ordinary table spectroscope, and lantern? And how may wave-lengths be calculated by its means? Any other useful information will oblige.—LYMNOS.

[97606.]—**A Geometric Difficulty.**—Through a given point, P, in the circumference of a circle, to draw a



chord, PR, cutting a given diameter in Q, so that the segment QR of the chord may be equal to a given straight line. A solution of this, or any comment that may suggest a solution by plane geometry, would greatly favour.—A. J. D.

[97607.]—**Telescope.**—I have long desired to make a telescope of large aperture, and have at last, after reading of Mr. Glass's achievements, decided to make an 8½in. Newtonian of 84in. focus. Would some reader kindly clear up the following points for me?—(1) What should be the dimensions of the plain elliptical mirror, and what distance should its minor axis be from the face of the speculum? (2) Using the telescope terrestrially, what would be its maximum power, with good light, under average atmospherical conditions? I am making a machine to grind the speculum, like that made by Mr. Glass. (3) In this machine what should be the stroke of the grinder and polisher for an 8½in. mirror? (4) What should be the (a) size of and (b) space between the leaden facets and the pitch facets of the grinder and polisher? (5) What pressure should the grinding and polishing tools exert on the speculum? (6) Where can I get a good book on grinding and silvering telescope mirrors?—R. E. WATTS.

[97608.]—**Water Power for Electric Lighting.**—I am desirous of putting an electric light installation of some 150 lights into a country house, using water power. Will Messrs. Webster Michelson or someone else kindly inform me if I can get sufficient power from a breast wheel, 14ft. in diameter and 3ft. 5in. wide, with an available fall of 9ft., to charge a set of accumulators, sufficient to run 80 16c.p. lights for eight hours? The supply of water is practically unlimited, or only limited by the size of the stream which conveys it from the dam on the river. The distance of the house to be lighted, and accumulators from the water-wheel and dynamo, is 1,200yds. I should prefer not to have to work the dynamo for more than six hours per day, as the same power with another [illegible] works a sawmill when required.—ROYAL NAVY.

[97609.]—**Polyphone Attachment for Phonograph.**—Have any of our readers any experience as to the construction of this fitting, which is described in the "E. M.," No. 1797, Sept. 1, 1899? It seems to me to be a superb idea, and one simple of putting into effect. The phonograph is hardly clear enough for a fellow to copy from. Is the spectacle-frame hinged? and does the split boss or clip in sketch No. 2 grasp the sliding tube? I don't see how the fitting can be put on an ordinary phonograph, unless the whole of the spectacle-frame is removed. Can someone say who knows? Does our friend R. A. R. Bennett know anything of its merits? As I have nearly finished making a phonograph (which I shall shortly describe, with the Editor's permission), I should like to have the latest addition. What is a Bettini reproducer? Does it make much improvement in the speech of phonograph? What is about the pitch of teeth and the diameters of the train of three wheels which works the screw of 50 threads to the inch, carrying the spectacle-frame. I had three wheels cut (and they were beautifully done) for mine; on the ¾in. wheel there were 24 teeth, and on the 1½in. wheel 48. Of course, this was all right as regards the proportion of numbers, but the row those three wheels kicked up completely drowned all reproduction by the stylus. Have I had them cut too coarse a pitch?—SLIDE-RULE.

[97610.]—**Grammaphone.**—Will any of "ours" kindly help me if they can? Having built a grammaphone, I should like to make my own records, as I find it rather expensive to give 2s. 6d. for every record I want, and then only have songs and music of people I do not know. 1. What is the record to be made of? If a composition, I should like description of same. 2. Will an ordinary needle scratch the lines? 3. Shall I want a fine-thread screw to carry the sound-box to the centre of record-plate? And, if so, how many threads to the inch, and at what relative speed should record and screw travel at? Should I want a different diaphragm? If so, please give description.—CHUFFY.

[97611.]—**A Problem.**—Will any reader of the ENGLISH MECHANIC solve the following, which I give in its original form? "I have a spherical cheese 1ft. in diam. A sphere taken from the centre, 1in. in diam., weighs exactly ½lb., and is worth 1s. 6d. per pound. The surface of the cheese is worth 1s. 2d. per pound. The difference of weight of cheese from the centre to the surface is in the same ratio as the price. It is required to find the size and weight of a central sphere of this cheese, the value of which is to be exactly 5s." The working will oblige.—A. H. W.

[97612.]—**Constant Voltage.**—I have an apparatus which works well with 12 volts of electricity. The current is made and broken about thirty times per minute, and is only on a fraction of a second each time, and will at the most be used eight hours per day at above rate. Now, what I want is a constant supply of 12 volts when each contact is made. I have tried E.C.C. and National batteries, but these have soon grown weak. I know very little about the construction of batteries. Would some kind of accumulator do? Would someone kindly tell me what kind of battery, &c., I should require, or other information that would help? I want the battery clean and easily portable.—VOLT.

[97613.]—**Percussion Powder.**—Would any reader of the "E. M." give me a recipe for a percussion powder for putting into small rim-fire cartridges? I have tried chlorate of potash and sulphur mixed, but it does not seem sensitive enough. It should be capable of being made into a paste, so that on being poured into the cartridge it would solidify and fill the little rim. I believe the substance that is put into the small paper caps for toy pistols would suit my purpose very well if only I could find out what it is composed of.—AN OLD SUBSCRIBER.

[97614.]—**Nautical Telescope.**—Could any one of "ours" kindly tell me the cause of extremely bad definition of old nautical telescope? At a distance of twelve yards objects are clearly defined; but beyond that they become hazy in proportion to distance of removal. Its length from object-glass to eyepiece is 3ft. (36in.), outer tube of mahogany 19in. long, and sliding tube 17in. The object-glass is of 1⁹⁄₁₆in. aperture, and formed of two lenses—one convex crown glass in front, and one concave flint glass behind. The sliding tube has two lenses in small tube about 12in. from eyepiece, which has also two lenses. These lenses are all perfectly sound and clear. I would like to know whether the fault can be remedied, and also whether such a telescope would be of any use astronomically, and what alterations it would require. The lenses are all removable, and do not appear to be other than those put in when new. The sliding tube bears the inscription, "Hughes, London, Day or Night."—SPHINX.

[97615.]—**Electrical.**—Will any electrician kindly tell me the probable output in volts and ampères from an undertype dynamo? The armature is laminated, 3in. long, 2in. diameter (tripolar), wound with 27 yards No. 22 s.c. wire; fields, 2in. section (square), 4in. in height, wound with 2lb. No. 22 c.c. wire in shunt. What speed ought it to be driven at? Could I charge a 12-volt accumulator with this machine?—FRONTAL ATTACK.

[97616.]—**Jesse's Acetylene Generator.**—Will the correspondent (letter 43265) on Jesse's Acetylene Generator answer the following questions? (1) Will compo. gas-pipe do for the tubes mentioned, the large one in holder being of a larger size to slide as holder rises? Is this so? (2) Will ordinary gas-burner do? (3) How large will holder and generator be for, say, one burner to be kept on for three or four hours? (4) I presume the generator is lined by a water jacket to keep it cool. Does it fill from the vessel in which the holder is? (5) Is it not a lot of trouble to refill with carbide, and to get the mud out? I suppose the feed-hole is large enough to get one's hand in. Is this so? (6) If any gas is left in holder when the generator is refilled, what is to stop it coming back to same? Is there a tap? (7) Will the receptacle for purifying ever want refilling? (8) Will the seams of all parts do soldered?—S. R., Bromsgrove.

[97617.]—**To Mr. Bottone.**—Seeing your reply (96963) on dry cells, I have made the cell. I have half filled it with sawdust, with which I put half-pint of

water, 1oz. of chloride of zinc, 2oz. of salammoniac, and ½oz. of glycerine. This I soaked in a jar for four days, and then I made another paste of 1oz. of powdered carbon, ¼oz. granular black oxide of manganese, 60 grains of rouge, with sufficient golden syrup to make the paste, which I pasted on the carbon plate. I next placed a piece of cork in the bottom of the cell, and then filled in with the soaked sawdust, and then filled in with pitch. I had to use golden syrup, as I cannot get treacle. I do not know if that will make the difference. The cell will not ring my bell.—Constant Reader.

[97618.]—**Air Silencer.**—Will some reader kindly describe the construction, with a sketch, of silencer for air-inlet to small gas-engine, 3½in. bore, 5in. stroke, 250 to 300 revolutions per minute? It is very noisy when drawing in air on suction stroke. There is 8in. length of ¾in. pipe to air tap.—Tudor.

[97619.]—**Repairing Stone Steps.**—There is a powerful cement for repairing steps or making-up stone steps. Can anyone inform me what it is composed of? It makes a smooth surface, and is as hard as rock.—F. H.

[97620.]—**Concrete Floor.**—I have a concrete floor, the surface of which powders, covering everything with fine dust. I wish to be informed how to cheaply make it have a hard, smooth surface that will not powder and stand a fair amount of wear.—J. H. H.

[97621.]—**Vinegar.**—How can I make vinegar from old ale? I have a few gallons turning sour, and I know it can be done; but how to do it remains a query. How is malt vinegar made, and why is it there is so much difference in the flavour of vinegars?—Jimmy.

[97622.]—**Charging Accumulators.**—My charging switch is also the discharging. By having a six-way charging and discharging switch put on, could I charge cell 30 ampères while discharging 30 ampères, cells taking 60 ampère charge? And would it not be very economical, as our discharge is generally from 30 to 40 ampères?—A. Archer.

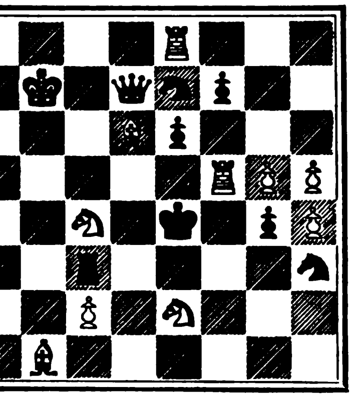
[97623.]—**Sizes of Telescopes.**—Will any reader kindly give a few particulars of the principal large telescopes—the "Lick," and that now being prepared for the Paris Exhibition, &c.—diameter of the o.g., focal length, magnifying power, diameter of mirror (when a reflector is used), &c.?—T. R. D.

CHESS.

All communications for this column to be addressed to The Chess Editor, at the Office, 332, Strand.

PROBLEM No. 1712.—By W. A. Clark.

Black. [7 pieces.



White. [12 pieces.

White to play and mate in two moves.

(*Solutions should reach us not later than Feb. 19.*)

Solution of Problem No. 1710.—By T. Taverner.

Key-move, Q-Kt 5.

NOTICES TO CORRESPONDENTS.

Problem No. 1710.—Correct solution has been received from Richard Inwards, F. B. (Oldham). H. B. F., G. W. U. ("The Q neatly outsteps the Kt in various directions"), J. E. Gore, Whin Hurst (May we wish "God speed and a safe return!"), A. Tupman, E. Hunt, Rev. Dr. Quilter ("A very instructive and excellent problem, and merits a first prize, although the key-move is not difficult to find"), N. M. Munro.

A. H. W., T. Chipperfield, B. E. D. (Genoa).—Only solution as above.

Metal, it is said, never rusts in the waters of Lake Titicaca. A chain or an anchor can be left it in two weeks, and will be as clean and bright as when it came from the foundry.

The production of aluminium in the United States last year did not greatly exceed that of 1898, when the output was 5,200,000lb. The prices of this metal remained practically unchanged through the greater part of the year, a slight reduction in quotations having been made towards its close. The selling prices in the United States for No. 1 ingots, 99 per cent. pure, range from 33c. to 37c. per pound, and No. 2, 90 per cent., from 31c. to 34c., while rolled sheets held at 42c. and upwards per pound, according to quantity purchased. The production continues in the hands of one company.

ANSWERS TO CORRESPONDENTS.

*** *All communications should be addressed to the* Editor *of the* English Mechanic, 332, *Strand, W.C.*

HINTS TO CORRESPONDENTS.

1. Write on one side of the paper only, and put drawings for illustrations on separate pieces of paper. 2. Put titles to queries, and when answering queries, put the numbers as well as the titles of the queries to which the replies refer. 3. No charge is made for inserting letters, queries, or replies. 4. Letters or queries asking for addresses of manufacturers or correspondents, or where tools or other articles can be purchased, or replies giving such information, cannot be inserted except as advertisements. 5. No question asking for educational or scientific information is answered through the post. 6. Letters sent to correspondents, under cover to the Editor, are not forwarded, and the names of correspondents are not given to inquirers.

*** Attention is especially drawn to hint No. 4. The space devoted to letters, queries, and replies is meant for the general good, and it is not fair to occupy it with questions such as are indicated above, which are only of individual interest, and which, if not advertisements in themselves, lead to replies which are. The "Sixpenny Sale Column" offers a cheap means of obtaining such information, and we trust our readers will avail themselves of it.

The following are the initials, &c., of letters to hand up to Wednesday evening, Feb. 7, and unacknowledged elsewhere:—

Interested.—G. E. Bonney.—Electric Sign.—R. W. B.—Young Electrician.—Jack of All Trades.—J. E. L.—Robbie Burns.—Silver Plume.—Theodore Brown.—Ajax.—Acetylene.—Bird.—Dragoon.—Grove.

G. J. Cocks.—We know nothing of them. If you want to make inquiries, you should write the Superintendent of Police, Derby.

Slide Rest.—When suggestions of the sort referred to are offered, readers should try them for themselves—if they think it worth while. We really cannot spare space for replies to questions asking whether such "are successes" or not.

F. C. Lambert.—Linen or cotton will do, or the special material to be seen on mounted maps. Stretch it over a board and damp it, then paste the map and lay it on, letting the centre touch first. Work out towards the sides. Press down with another board until dry.

A. M. B.—The original "graph composition"—a patent—was 1 part of glue, 2 parts of water; when melted, add 4 parts of common glycerine, a few drops of carbolic acid, and sufficient whiting or white-lead to make the whole milky. Sulphate of baryta is preferable to white-lead. There are other recipes, but they are much the same. 2. For blackboards, see p. 323, No. 1704, Nov. 19, 1897.

C. O. D.—"Gas, Oil, and Air Engines," by Bryan Donkin, jun. (London: Charles Griffin and Co., Ltd.) But why not look up the subject in our back numbers and recently? Any of the large booksellers in Leeds could probably show you the works on the subject, or some of them.

Geo. F. Scott.—You would find all about Tidal Power inventions by searching at the Patent Office Library. There is much information in back volumes.

A. Paull.—We have no advice to offer, and cannot adopt your other suggestion. The box awaits your messenger.

E. R. D.—One like the Perkins or the Serpollet, in which the plates are so hot that the water injected flashes into steam immediately. 2. Would it be possible to get the burning-glasses sufficiently close to the camps? 3. Do not know. Where did the description of the gun appear? 4. Liquid air is still on view at the Royal Institution, and is being used every day nearly for experiments and investigations. If you refer to the liquid air schemes in America, we are unable to give any further information. Probably the companies were not so successful as was anticipated. See answer to "Thrasna" below.

Jimmy.—Anything that will encourage the acetous fermentation will do; but the query is inserted, as most of the flavour depends on the way the fermentation is carried on.

W. H. Turner.—It would be advisable to see a medical man, and ascertain if there is any organic disease. For a good, safe hair dye see the Mutual Aid Column of the *Weekly Times and Echo* last week.

A. Archer.—The nature of the battery cell is not stated, but probably there was a mixture of hydrogen and air, and so the explosion when a light was brought near.

Tin.—See many recipes in back volumes. Guttapercha mixed with pitch is a good common one; but we know of nothing better than the solution of indiarubber properly applied.

York.—You will require air-compressing plant, or else ammonia plant. The half-horse engine will be of little, if any, use for such a purpose. See articles in back numbers.

Thos. Greene.—Only by inquiry of the engineering firms, or by recommendation of someone known to the firm. Some firms do not care to take apprentices at all; but from the terms used the boy is to be a "gentleman apprentice," and for that a rather heavy premium must be paid.

F. J. Caldar.—We cannot tell you whether the lenses are easily procurable, nor what would be the probable cost. You must apply to those firms who manufacture lenses. Any of those who advertise in our pages would tell you at once whether they manufacture such lenses, and the price.

Thrasna.—A full illustrated description of "The Latest Liquid Air Plant" will be found in No. 1793, Aug. 4, 1899. Do not know where you can purchase liquid air in this country; but it is made at the Royal Institution, and is rather expensive.

F. H. Ewer.—Too long. We have given all the space we can spare to the subject, which has quite got out of the range of *practical* interest, and we are very short of space just now.

W. W. Rickmers.—1. The curious visual deception referred to has been more than once pointed out and examples given; thanks all the same. 2. We have tried the experiment, and we certainly cannot find any "clinging" of the pencil shavings to the desk. There is now and then the most momentary pause, due probably to impact, but that is all.
